Messrs. Bidder, Hawksley, and Bazalgette's Report of 1858, in which the level of the water in the wells all the way down the valley of the Thames is given, from which you will see that there are a very large number of wells, the surface water of which is at a level below that of high tide. The levels of a number of wells at Erith are given, in which the water varies from 4 feet only to 2 feet above ordnance datum, 2 feet being the mean tide level.

(*Mr. Bidder.*) As you referred us to the page, I see the note that, "The water in the wells, although "influenced as to supply by the state of the tide, is "not brackish, the water beds in the chalk dipping "to below high water in the Thames are dammed up "during high water, and, consequently, the water "will rise in the wells," showing that there may be fluctuation in the wells without any communication with the water in the river.

7976. (*Mr. Lumley Smith.*) Now, almost the last thing I have to ask you, but which I ought to have asked you before, speaking about the solid matter which got into the river: we have heard that a certain amount of mixing goes on between what comes from the outfall and the sea water, and a certain amount of mixing goes on between what comes from the sewers and the land water. To what extent would the mixing action affect the solid matter which is not in solution, but in suspension?—The mixing action would affect everything which is capable of mixing, but it would not affect the solid matters which fall down to the bed of the river.

7977. Then, as far as the tests for mixing are concerned, would they at all show what quantity of solid matter has been deposited in the bed of the river?—No; a large quantity of solid matter clearly is deposited, and that would not be affected at all by the mixing action; that solid matter could only be carried away either by a sufficient velocity of flow in the river, or by being gradually dissolved, if it were capable of being dissolved, by decomposition, being carried away then in a soluble form.

7978. Which in your judgment would reach the sea the fastest; that which was in solution, or that which was in suspension?—Naturally everything which is capable of mixing gets to the sea very much quicker than the solid matter which lingered on the bed of the stream.

7979. As what comes down from the sewers mixes more or less with the sea water, and oscillates up and down with the tide, would it tend to deposit certain quantities of matter which were in suspension?—Yes, it would. I find that if we take the velocity flow of the sewers upon the south side, of which we know the most, that velocity flow is greater than the velocity flow of the ebb of the river itself. That is to say, assuming the sewer to be running full or half full, and the matter coming out of the sewer at a high velocity and going into the river at a slow velocity, the tendency must be for it to deposit. In the case of the north the velocity of flow in the sewers, as far as I know, is about equal to the flow of the ebb tide; they about balance each other, assuming that they are running full.

7980. I think one of the witnesses gave us the result of his experience with regard to the pace which was required to carry along suspended matter, and to prevent the solid matter sinking to the bottom; do you recollect what that was?—He gave various rates in sewers, but the rate of velocity in the southern outfall, when running full or half full, is about 194 feet per minute, and the flood tide itself is first about the same, but the ebb tide is about 160, which is about equal to the velocity in the sewers upon the north side.

7981. As the velocity slackened, would the tendency to deposit the solid matter increase?—Certainly, and especially near the turn of the tide; and in slack places the solid matter of course goes down and forms mud banks.

7982. At extreme low water and extreme high water the water would necessarily be slack at some part of the river?—Yes.

7983. (*Sir P. B. Maxwell.*) Are you referring to question and answer No. 6319?—Yes.

7984. (*Mr. Lumley Smith.*) In your judgment would the same rule apply to the sewers as would apply to the river?—It would apply to an ordinary river but not to a tidal river; the same law does not apply to a tidal river as applies to an ordinary river, but in an ordinary river the flow would carry the solid matter to the sea. Wherever there is a slack in a tidal river you would naturally have a tendency to deposit.

7985. (*Sir John Coode.*) Would not all this very much depend upon the angle at which the one would impinge upon the other?—Yes; but you may have a deep place and a deflection of the stream into the bottom which would always keep it a deep place, and then the deposit would take place in the shallower water.

7986. But two streams may meet so as to join in harmony, or they may meet at right angles?—I have in view a vertical angle, that is to say, you have exactly the same deflections in the vertical plane of an ordinary river as you have in the horizontal plane. You may have a deep hole, and the water may enter it at a considerable angle, and the consequence is that it is deflected down on to the bottom, and reflected off, and always keeps that a deep place in the river. Although the natural sectional area of the river may be so much greater at that point, yet it never silts up; the hole in the bed of the river always remains a hole.

7987. (*Chairman.*) Taking a slow flowing river, which you might think would deposit and have a level bottom, yet nevertheless you find deep holes in the bottom of it constantly?—That is so.

7988. I never could understand why it should be?—Simply that takes place in the vertical plane which takes place in every horizontal plane of a river.

7989. (*Mr. Lumley Smith.*) Have you anything to add with regard to the mixing as to the chlorine figures; have you compared at all the relative amount of chlorine at any of those places in your table which is printed at No. 7511 at high and low water with a view to this inquiry?—Yes.

7990. Have you anything to point out with regard to that?—Yes, there is a very curious point with regard to this. If you look at the amount of chlorine in the river at Barking upon this table, and the amount of chlorine in the river at St. Paul's pier, which is just about the range of the tide, you will find that upon the 14th of September, during the period of high water, there were two-thirds of the amount of chlorine in the water at St. Paul's pier that there was at Barking at low water. You must compare the high water with the low, because the water which is in the river at Barking at low water is, by tidal impulse, pushed up to the extent of the range; that which I have just mentioned was upon a spring tide. Upon the 22nd of September, it being a neap tide, you will find that the quantity is just one-third only. Then you come upon the 30th of November to a period when there is great dilution, and when the initial quantity of chlorine in the river will make a considerable difference; therefore if you deduct the 1·7, the initial amount of chlorine due to the river water, from the 5 at Barking, and deduct the 1·7 from the 2·8 at St. Paul's pier, you will see then that one-third exactly upon that neap tide is carried up to that point.

7991. The distance between those two places being, as you have said, about the range of the tide?—The distance between those two places is about the range of the tide.

7992. Although the water is pushed up from Barking to St. Paul's pier, you find a very different amount of chlorine?—Yes; you do not find all the water having gone up, or else as it goes up it mixes with the fresh water, and as it goes down it mixes with the salt water, and it is that mixing action that so much accelerates the rate of progress out of the river.

7993. I do not think you have anything to add with regard to the tables you have handed in? Have

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

you sufficiently explained them all?—There are tables on page 5 which were put in to show the amount of the mixing action going on, and on the diagram I have put before his Lordship I marked in red figures the amount of chlorine at every period according to the number upon the diagram. Upon the last occasion I put in a table, and the diagram before you shows the several quantities of chlorine. A float being put in at low water at London Stone, it floated up a certain distance, samples of water being taken both at the surface and at half the depth of the river. The next day it is put in at low water at the point where it reached the previous day at high water, and so it is carried up the river; and these tables show the amount of the admixture which goes on all the way up the river. Then following that, there is a table referring to the water coming down the river; the distance the samples are apart is shown in one of the columns, and there you see the effect of mixing with sea water as you go from the fresh water at Teddington to the London Stone again.

*The table was handed in and is as follows:—*

SAMPLES of WATER taken on TIDE flowing up the RIVER THAMES.

| Date. | Amount of Chlorine in 100,000 parts of Water at Low Water. | Amount of Chlorine in 100,000 parts of Water, at High Water after Flowing up River. | Distance apart of Samples. | Number of Volumes of Water with the least Chlorine to make one with the most. | Remarks. |
|---|---|---|---|---|---|
| 1882. | | | Miles. | | |
| Oct. 29th | 1,277·5 | 1,215·0 | 13·40 | 1·05 | London Stone to Chalk. |
| „ 30th | 241·0 | 134·5 | 14·25 | 1·79 | Chalk to Crossness. |
| „ 31st | 4·4 | 3·7 | 11·25 | 1·18 | Crossness to Limehouse. |
| Nov. 1st | 1·7 | 1·7 | 5·20 | 1·00 | Limehouse to Vauxhall. |
| „ 2nd | 1·7 | 1·7 | 3·53 | 1·00 | Vauxhall to Wandsworth. |
| „ 3rd | 1·7 | 1·7 | 1·45 | 1·00 | Wandsworth to Beverley Brook. |

SAMPLES of WATER taken on TIDE flowing down the RIVER THAMES.

| Date. | Amount of Chlorine in 100,000 parts of Water at High Water. | Amount of Chlorine in 100,000 parts of Water at Low Water after Flowing down River. | Distance apart of Samples. | Number of Volumes of Water with the least Chlorine to make one with the most. | Remarks. |
|---|---|---|---|---|---|
| | | | Miles. | | |
| Nov. 4th | 1·7 | 1·7 | 17·80 | 1·00 | Teddington to Blackfriars. |
| „ 5th | 1·8 | 3·6 | 14·00 | 2·00 | Blackfriars to Crossness. |
| „ 6th | 50·0 | 343·0 | 13·67 | 6·86 | Crossness to Medway Canal. |
| „ 7th | 1,000·5 | 1,365·0 | 14·50 | 1·36 | Medway Canal to London Stone. |

7994. I suppose this mixing brings about a better state of things than if the water went out of the sewer and did not mix?—Yes, it does; formerly the caculations were made simply for displacement.

7995. My learned friend suggested that at night-time some of the floats might have got anchored. I believe you have had the float ranges coloured so as to show which is night and which is day range?—Yes; I have had them coloured so that the black lines show the nights and the red show the days. I have had an average of them taken, and it will show that the average of that particular sheet is that the night tides are rather a longer range.

7996. (*Chairman.*) In your judgment, does the progression of the float downwards, so far as there has been any, correspond with the quantity of fresh water added from above?—You will see that in many cases the floats have gone up to a certain extent.

7997. But upon the whole?—This simply shows the tidal oscillation which is going on, that is affected by so many conditions that it does not really show the progress out to sea. I would beg leave to explain the other tables which I produce. They will speak for themselves; but in these cases you will observe that we have taken the water as if, instead of being mixed with sea water, it had been mixed with a volume of tidal or Southend water, showing the ratio of mixing all the way down the river. It does not need any further explanation, but it makes very little difference in the calculations whether you calculate from this table or from the sea-water table.

*The following tables were handed in:—*

TABLE PRODUCED from CHLORINE TESTS SHOWING the QUANTITY of UPPER RIVER (TEDDINGTON) WATER MIXED with each VOLUME of TIDAL (SOUTHEND) WATER at VARIOUS PLACES on the THAMES.

| | September 14th. | | September 22nd. | | November 30th | |
|---|---|---|---|---|---|---|

| „ 7th | 0·27 | 0·0 | 14·50 | Medway Canal to London Stone. |

(*Sir John Coode.*) If I gathered rightly the question that fell from his Lordship, it was whether or not you found the distance which the float travelled down was influenced by the quantity of fresh water in the river.

(*Chairman.*) What I meant to say was whether it corresponded to it.

7998. (*Sir John Coode.*) I think, if you look at sheet 3 of your tidal observations, you will see that it does correspond with the quantity of water flowing over Teddington Lock?—Yes; you will find that above London Bridge the amount of water has a considerable effect upon the water flowing down the river, but below it has not much effect, and when the floods come they soon begin to drive the floats down the river.

*Mr. B. Latham, M. Inst. C.E.*

30 Jan. 1883.

Adjourned to to-morrow at half-past twelve o'clock.

# EIGHTEENTH DAY.

## Wednesday, 31st January 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANCOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.

W. POLE, Esq., F.R.S., *Secretary.*

Mr. BALDWIN LATHAM, Mem. Inst. C.E., called again; cross-examined by Mr. BIDDER.

7999. I have followed, with as much intelligence as I can, your three days of examination; but from all this mass of figures and statistics just tell me, to begin with, what conclusions do you invite the Commissioners to draw adverse to the present condition of the river?—The conclusion which I draw is that, the capacity of the sewers not being adequate for the present district, sewage is turned into the river at higher points which naturally lingers longer in the river, and at certain periods of the year tends very much to increase the pollution of the river.

8000. Granted all that, do you invite the Commission to draw a conclusion, or do you point to anything which leads to the conclusion that, as a matter of fact, the state of the river is unsatisfactory?—Certainly I do. I have already pointed out that there are conditions with regard to the water supply, and there are conditions with regard to the accumulation of mud, which in my opinion are highly detrimental to the districts below London.

8001. Granted that the conditions are adverse, do you point to any fact or observation as showing that at the present time, as a matter of fact, the condition of the river is unsatisfactory?—At the present time of course the river is extremely diluted.

8002. I do not mean at the present moment; I mean in a wider sense?—I mean generally that, under the conditions under which sewage is discharged at Barking and Crossness in the summer months, the river cannot be otherwise than most offensive and most prejudicial to the interests of those who use it.

8003. In point of fact, you put it in this way, "having pointed to certain conditions, I infer that it "cannot be otherwise than unsatisfactory"?—I have already stated in my evidence that under conditions which occur in the height of summer when this mud decomposes, and when no purification takes place, the river must be offensive.

8004. You have been engaged for a considerable time in making observations relative to this inquiry, have you not?—I have been engaged on this inquiry since June last.

8005. That being so, have you any fact or observation to lay before the Commission to show that, as a matter of fact, the condition of the river is unsatisfactory?—I have seen the river myself, on one or two occasions when I have been down it this year, simply bubbling up from the effects of fermentation, and black in colour; but I recollect a year or two ago, when I was going down in the summer, that it was very foul from Deptford to below Erith.

31 Jan. 1883.

8006. May I assume that what you saw this year was in the neighbourhood of Crossness and Barking?—It was between Barking and Erith.

8007. Was it in the neighbourhood of Crossness?—It was more or less all the way down the river.

8008. Was it in the neighbourhood of Crossness?—I say it was all the way from Barking to Erith.

8009. (*Chairman.*) Supposing you knew nothing about the river and nothing about the sewers, if we can suppose such a possibility, and you went up and down the river in a boat, would you say that there was anything wrong there?—Not at the present time; but in the summer of 1878, when I was down the river, it was certainly most frightfully offensive; it was like sailing upon the top of a cesspool, containing diluted cesspool matter.

8010. On one particular occasion?—This was in the summer time.

8011. Was the river in the same state throughout the summer?—When I was there.

8012. How often was that, do you suppose?—Upon that occasion I only went down the river and back again.

8013. (*Mr. Bidder.*) Will you just fix a little more precisely, if you can, the part of the river where you made that observation?—I have already told you that it was more or less so from Deptford to below Erith.

8014. What was the date when you made that observation?—In the summer time in 1878, probably in July, but the exact date I have forgotten.

8015. I suppose it was in relation to this water business?—I was down several times, but not down the river upon the water business; it was not upon that occasion.

8016. I will first clear away one or two minor matters to which you adverted yesterday. With regard to the question of the wells in the neighbourhood of the river, you referred to a certain well at Cross Street, Erith, yesterday, and you gave certain

*Mr. B. Latham, M. Inst. C.E.*

31 Jan. 1883.

statistics as to the amount of chlorine in it. You said, if I followed you rightly, that, assuming the chlorine came from the river, it followed that a certain portion of the well water was river water?—That is true.

8017. Having regard to the facts, do you believe that that chlorine did come from the river?—It is quite possible that it did.

8018. Having regard to the facts, do you think it did?—It is quite impossible to say for certain.

8019. Are you aware that there had been great complaints for a long time of a number of wells in Erith having been polluted by cesspools in the neighbourhood?—When I gave that evidence yesterday, I was careful to qualify it by the statement that it might be leakage from a cesspool.

8020. Were you aware that there had been great complaints of wells in Erith being polluted by cesspools in their neighbourhood?—I knew for a fact that it had been mentioned here.

8021. Were you aware, as a fact, that this particular well had been reported as having a cesspool in its immediate neighbourhood, and being polluted by it?—I heard what was read yesterday with regard to it.

8022. Now, with regard to the chalk quarry at Grays, you referred the Commission, in connexion with that, to a certain table, Table 9, in the Report of 1858, upon the main drainage, showing the level of water in wells situated in or near the line of the outfall sewers?—I referred to wells at Erith from this particular table.

8023. Now, I will ask you whether your attention was drawn to, and if so, whether you confirm the note on the right-hand side of the page. "Mr. Sturge, of "Northfleet, states that, in clearing the ground near "low water in the Thames for the foundation of a "wharf, he came upon a strong spring of fresh "water, which he walled round and preserved, and "it now furnishes a copious supply of pure water "not in the slightest degree brackish. There are "several other springs along the shore near low-"water line, all fresh water, proving that the water "bed in the chalk slopes to about the level of the "low water in the Thames." Is that in accordance with your own observation?—That is quite true with regard to the water in its natural state, but that condition is immediately altered the moment you begin to pump in the neighbourhood.

8024. I had better read the whole of the note. "At Springhead, about half a mile south of North-"fleet, near the Referees' line, the springs boil up "in numerous places to near the surface, about six "feet below Trinity high water. Mr. Sedger states "the water in his well rises and falls with the tide, "but the water is quite pure. The water in the "wells, although influenced as to supply by the state "of the tide, is not brackish; the water-beds in the "chalk, dipping to below high water in the Thames, "are dammed up during the high water, and, con-"sequently, the water will rise in the wells." Is that in accordance with your own observation?—It is. Some years ago I made a little sketch, which explains the theory of tidal wells (*exhibiting the same*).

8025. It is so, that, although the wells may fluctuate in their level with the state of the tide, it by no means follows that there is any actual transfer of water from the river in the tideway to the well?—I have known the case of a well not far from Plymouth which is absolutely dry at low water, and at high water it overflows and runs into the tidal way, being fresh water, but if any exhaustive pumping were to take place from these same fissures from which the water escapes at low water into the river, the tidal water would enter.

8026. But, speaking of the chalk in the London basin, that is fed from high lands both north and south, is it not?—It is fed from high lands upon the south as regards one portion, and a portion upon the north is clearly fed from high lands upon the Essex side.

8027. And the subterranean flow of the water is from those high ridges towards the bottom of the valley in the river?—That is so; but it is known that the quantity of water varies immensely, coming down in the chalk formation from year to year. The moment you begin to pump, you alter the whole conditions, and you may have water flowing back through the apertures by which the water escapes at ordinary times.

8028. And with regard to your observations at this particular chalk quarry at Grays, you said that you had got some observations of the year 1860, and you were kind enough to say that you would give us the reference to them.

*The Report was handed in, and is as follows:—*

"REPORT ON THE WATER FROM THE SPRINGS AT GRAYS, ESSEX.

"I visited Grays on the 30th August, in company with Mr. Meeson and Mr. Beale, jun., and had an opportunity of examining the copious springs originating from the chalk of that locality. The water was perfectly pellucid, and possessed a sparkling aspect. Its taste was most agreeable and refreshing. The temperature obtained by immersing a thermometer in one of the springs as it flowed from the chalk was 53° 5″; the mean temperature of the atmosphere accurately ascertained being at London 61° 4″. This characteristic would be most valuable should the water be supplied to London, since a difference of temperature of eight degrees between the air and the water would be extremely grateful to the palate, and would afford a strikingly favourable contrast with water derived from rivers, which, in this latitude, have an average temperature above that of the atmosphere. After being kept for a fortnight the water exhibited no disposition to deposit any sediment and no appearance of vegetable growths, as frequently occurs with river water when allowed to stagnate. I could detect no traces of animal life in the water, whereas in river waters, even after filtration, the absence of evidence of animal life can rarely be affirmed.

"I have carefully tested for the presence of organic matter, and have only been able to detect a trace, but in such minute quantities as to render it impossible to assign any weight to this constituent. The water having been taken at the end of an unusually wet month, when water is most likely to be contaminated with organic matter from the surface by impregnation from rain, falling on cultivated soil, I think it very probable that under usual circumstances there may be no organic matter at all in solution, except in a condition of oxidation, and, therefore, comparatively innoxious in a sanitary point of view. When subjected to quantitative analysis it yielded the following composition—per imperial gallon—in grains:—

| | |
|---|---|
| Volatile matter - - | 1·60 |
| Silica - - - | 1·60 |
| Sulphate of Potash - | 1·30 |
| Sulphate of Lime - | ·95 |
| Carbonate of Magnesia - | ·96 |
| Carbonate of Lime - | 16·13 |
| Carbonate of Soda - | ·30 |
| Nitrate of Lime - - | 1·23 |
| Chloride of Sodium - | 2·33 |
| | 26·40 grns. per gal. |

The chalk present in solution gives the water 16·13 degrees of hardness, which could be removed by the liming process of Dr. Clark. The small amount of sulphate of lime dissolved in the water, compared with that in the waters at present supplied to the metropolis, would render it an exceedingly soft water if treated by the softening process referred to. But, taking the water as it now issues from the chalk at Grays, I consider it well adapted for the domestic

supply of the metropolis, and superior in a sanitary point of view to waters obtained from rivers and open canals.

"ROBERT DUNDAS THOMSON,
M.D., F.R.S.S., L. & E.
Court House, St. Marylebone,
17th September 1860."

8029. This, as you said yesterday, shows that in 1860 that gentleman reported having found 2½ grains of chloride of sodium, you say that your analysis found 13½ parts of chlorine?—Yes, at high water; that is 13·6 in 100,000 parts. This paper gives the figures in grains per gallon.

8030. Are you aware that 13 parts of chlorine in 100,000 parts is by no means an unusual proportion in fair chalk water?—A most unusual thing.

8031. You are prepared to say that, are you?—I am prepared to say that most distinctly, from my knowledge, with regard to the chalk formation in which I have been making special observations for seven years.

8032. Will you produce for me the analysis which you had taken, and which showed those 13 parts of chlorine?—I think the chemists had better produce their own analyses.

8033. It will be produced?—It will be produced.

8034. By whom was it made?—By Professor Way, these tests were made; but Dr. Tidy has analysed the water in the neighbourhood, and he will be able to speak to it as well, as he was engaged upon the water question.

8035. (*Chairman.*) Had your analysis of the chalk water been limited to what, I believe, are called the waters of the North Downs?—No; I have generally collected statistics both from the North Downs and from the South Downs, and in the case of the chalk in the neighbourhood of Hull, in Yorkshire.

8036. And you find that 13 in 1000,00 parts is a large proportion?—Except where it is near the sea, and, as I said yesterday, there are wells near the sea which contain a very much larger quantity, but for inland wells it is an enormous quantity.

8037. (*Mr. Bidder.*) I will tell you what I want to put to you at once; was there in that analysis any evidence of sewage contamination?—I believe that the samples were only taken for the purpose of ascertaining the quantity of chlorine, for my own instruction, for the purpose of working out the relative volumes according to the formula which has been introduced, and the analyses only show the amount of chlorine in 100,000 parts.

8038. Now, passing on to your evidence of yesterday, you made an observation with regard to the sewage having a tendency to deposit whatever solid matter was in suspension as the velocity diminished? Yes, certainly.

8039. In point of fact, is not the sewage brought to absolute stagnation in the reservoir at the outfall?—Part of it is.

8040. The bulk of it; of course, there may be a certain quantity which happens to run through just at the time when the outfalls are opened, but as regards the bulk of it, it is brought to a condition of absolute rest?—You cannot say absolute rest, it would be to a slight extent stirred up by water flowing into it, but still to a great extent it will be in a state of comparative quiescence where there is no direct flow.

8041. Therefore the matter which has been upborne by the velocity of the stream, and is ready to fall as soon as the velocity ceases, has an ample opportunity of doing so in the reservoirs themselves?—Yes, and I find, in reference to one of the earlier reports, I think it is one of the 20th of July 1858, of Messrs. Bidder, Hawksley, and Bazalgette, that they point out that the reservoirs are purposely to be used as reservoirs of subsidence, so that the matter might accumulate at the bottom and not flow into the river in times of storms.

8042. In connexion with this matter, you gave certain figures yesterday as regards the amount of solid matter that comes out of the sewage in the year, and you quoted that report as to a certain extent confirmatory; I think it was at page 74?—Yes, it was 250 tons a day.

8043. I suppose you were referring, when you mentioned 250 tons, to that passage at page 74; let me read the whole passage in order that you may have it all before you. "In considering the causes "of the turbidity of the Thames, it should be remem- "bered that the amount of solid matter of every "description which is poured into the Thames by "the London sewers is a comparatively insignificant "quantity, certainly not greater than 250 tons a day, "a quantity scarcely exceeding that which is cleared "out of the docks by manual labour only. The mud "incident to the Thames as a tidal estuary is largely "in excess of the mud projected into the Thames by "any population on its banks; the former is per- "manent, whilst the latter is perpetually undergoing "destructive decomposition." Now, do you agree with that? There are two assertions there, one that, supposing it is 250 tons a day, it is quite insignificant compared to the mud which is due to the Thames as a tidal estuary; and the other that, whatever its amount, it is perpetually undergoing destructive decomposition?—I say that a certain portion of the solid matter cannot undergo a destructive decomposition.

8044. First, let us take it that it is insignificant in proportion to the mud naturally due to the Thames as a tidal estuary; what do you say to that?—I look upon the mud which is brought up by the flow of the tide as being the same pretty well every day, simply passing backwards and forwards by the flow of the tide, but in the case of sewage it is a fresh volume added every day.

8045. Is it not the fact that the passage of the tide, the action of the in-flowing tide, the waves produced by the wind and by steamers, and so on, are constantly abrading soil from the banks of the Thames?—Yes, exactly; that matter is partly made up of the solid matter which has gone in as sewage.

8046. Not that which is part of the solid banks of the Thames?—I am speaking generally of the mud.

8047. Then is it not the fact that a large quantity of mud comes down by the upland water?—There is a certain quantity, but very small comparatively, which discolours the water. For instance, if you go up the river to-day, you will find that it has a peculiar milky brownish appearance, but that amount is insignificant compared to the total matter.

8048. Do you agree or not with the assertion that the amount of solid matter introduced by sewage is insignificant compared to that which is introduced by natural causes?—I cannot say that it is insignificant.

8049. (*Chairman.*) That is rather an awkward word; it might be insignificant in point of bulk, but not in point of effect. I suppose that one grain of arsenic might be insignificant in point of bulk.

8050. (*Mr. Bidder.*) I am at present only on the point of quantity?—I say that in course of time this mass of mud which is passed into the river from the sewage accumulates to an enormous extent, and therefore it cannot be looked upon as insignificant as regards its effects upon the character of the river itself.

8051. Never mind its effects; do you agree for the moment in the fact that it is insignificant in quantity; is it insignificant in quantity?—If you take the whole quantity in a particular day in the whole of the Thames, and the mud in suspension of all sorts, and compare that which comes in on that same day with what comes in from the sewers, of course the latter bears a very small proportion to the whole.

8052. I do not wish you to limit your answer to a particular day, but, taking the whole year round, taking the quantity produced by the sewers, and the quantity produced and added by natural causes, is not the amount of sewage of insignificant quantity?—No,

*Mr. B. Latham, M. Inst. C.E.*

31 Jan. 1883.

it is not, because in the case of natural mud it is the same mud moving backwards and forwards, whereas in the case of sewage it is fresh mud brought in every day.

8053. (*Chairman.*) But there is fresh mud introduced every day by natural causes?—Not much, except in times of flood.

8054. And the amount of mud produced by the wash of the steamers and so on?—That is all the same mud reproduced.

8055. If you were to dip your vessel into the river in an average condition, what proportion of mud other than sewage would there be to sewage mud?—I think the chemists can answer that question better than I can.

8056. I should say not?—It would require a chemical analysis to determine this question.

8057. I thought you had given us the amount of solid matter that flowed into the river?—Yes, I have.

8058. I should have thought that you would have known what proportion of natural mud there would be in ordinary water?—I do not know what amount of suspended matter there was in the river upon these particular days throughout the river, but our chemist would know.

8059. (*Mr. Bidder.*) Has your attention been drawn to the observations which were taken, I believe jointly, by the late Mr. Keates and Dr. Tidy, who was upon your side of the table upon the last inquiry, the mud inquiry, which are printed in the volume the Commissioners have before them; it is in the tables before page 1176?—I have not seen anything in that inquiry relating to chemical analysis.

8060. This is not as to chemical analysis; but as to the tons of mud that come over Teddington Weir, there is a series of tables, and the particular table to which I am now referring is Table C. I draw your attention to certain observations in the month of February 1880, showing an average of 445 tons a day?—I observe that this is in a particular month only, namely February 1880, a month of course when there would be much more likely to be floods than in other periods of the year, and, therefore, much more likely for suspended matter to be going down, when it is, as shown to be, 444·9 tons upon the average of that month.

8061. (*Chairman.*) That is a wet month?—It used to be called February fill-ditch when I was a boy. I should like to point out to you upon that table that upon one occasion it is as low as 5·8, and upon another day it is 4666·2 tons per diem.

8062. (*Mr. Bidder.*) You say that that is a month of flood, but I want to draw his Lordship's attention to what the arbitrators say at page 22 of their Report at the end of the volume. They say, "The Thames is a "comparatively clear stream except in time of flood," that is of course the Upper Thames. "On the "other hand, a series of observations was specially "made during the month of February 1880; the "samples of water, instead of being collected one "foot below the surface, were taken daily as nearly "as possible at the mid-depth of the river. One "sample taken, when the flow past Seething Wells "was at the rate of 81,000,000 cubic feet per 24 "hours, showed the total solid matter in suspension "to be as little as six tons in 24 hours; but a sample "similarly taken when the flow had increased "sixfold in consequence of rain showed that the "volume of solid matter amounted to 4,666 tons in "the same interval of time. It is to be regretted "that a large flood did not occur during this month, "and that we have been unable to obtain evidence of "the amount of matter in suspension brought down "by the upland waters of the Thames under such "circumstances," so that it was not a month of exceptional flooding?—No, but you will see quite clearly from this table that the ground was excessively sensitive, as is shown by the marked fluctuations from day to day in the quantity of solid matter coming down, that is, sensitive to the rain flowing off.

8063. Now they go on to say, speaking of the foreshore and saltings, "The tidal estuary of the Thames "is stated to be about 70 miles in length, in which "about two-thirds of the foreshores are protected "from the wash of the water. The tidal tributaries, "including the Medway, appear to be of about the "same length, but of the proportion of protected "foreshores in these no evidence was given. The "saltings are portions of the foreshore which are "comparatively level, covered with vegetation, and "overflowed at high water for the most part only at "spring tides. The wash of the river, especially "that caused by winds and by steamers, disintegrates "the sides of the saltings. The balance of loss which "the river banks and saltings in the Thames have "suffered was estimated to be 766,000 cubic yards in "the whole period since the outfalls were opened, to "which an addition of 90,000 cubic yards were esti-"mated as contributed by the tidal creeks; this would "afford somewhat less than 400 tons a year for each "mile of foreshore." Have you any observation of your own to make upon that point?—Taking the outfalls to have been opened in 1864, and the inquiry was in 1878, that is 14 years, and only 766,000 cubic yards in the whole period were washed in, divide that by 14, and it shows a very much less quantity of matter annually washed from the saltings than that which comes from the sewers.

(*Chairman.*) It is about a fourth part, is it not?

(*Mr. Bidder.*) The Commissioners performed the calculation and made it 400 tons a year for each mile of foreshore, that is 56,000 tons a year.

(*Witness.*) It is less than a third of the total quantity, as I have shown, brought in by the sewers, calculated upon the basis of the ABC process.

8064. But it is 400 tons per year per mile of foreshore?—I have told you that the amount of solid matter brought in by the sewage as shown by ABC experiment is about 200,000 tons a year, that is nearly four times this. I will give you the right number, it is 54,714 tons a year from these saltings, that is, taking 14 years.

8065. That looks like a good deal more than a third of your 250 tons a day?—But I did not give the 250 tons a day.

8066. The next thing that the arbitrators point out is the denudation of the bed of the river as supplying materials, do you agree with that?—I should think it is a very difficult thing in the Thames to decide what has been taking place from natural denudation, and what has been taking place from the dredging which is constantly going on.

8067. Then at page 23 the arbitrators point out that "A proportion of suspended matter is beaten up "in storms from the sand and mud banks at the "mouth of the river, and is carried along by the "in-flowing tide, as is the case in all tidal estuaries," do you agree with that?—It is quite possible at certain periods, but you must remember this, that it can only be carried 12 miles up the river.

8068. Then at the same page they say, "the dry "weather sewage contains on an average 23 grains "per gallon of suspended matter;" how is that to be reconciled with your 57?—I say that is utterly fallacious. I have looked at those reports, and I find that there is an enormous discrepancy in them.

8069. You are aware that this is the report of the arbitrators after a long and careful inquiry into the analyses produced by chemists; it is rather a strong thing to say that it is utterly fallacious?—I say it most distinctly, having a very good knowledge of what the solid matter in sewage is. I say these tables given by the chemist to the Metropolitan Board of Works show that in the north of the Thames it is 25½ grains, and in the south it is 21½ grains. Now, as we know that even in dry weather the sewage upon the south is mixed with 50 gallons of water per head per day, and the sewage upon the north with 30 gallons per head per day, those two proportions of solid matter bear no such relation to each other, as the relative volumes show. If the south is right, the north

ought to have shown a very much larger proportion of suspended matter. We know that a very large amount of suspended matter rolls down the bed of the sewer and escapes collection in small samples.

8070. You say the conclusion of these gentlemen is utterly fallacious upon this point?—Whatever their conclusion is, I differ entirely from them.

8071. The ground for your own conclusion, I understand, is a certain ABC experiment, which you referred to, which was carried on at Crossness; that is the only one you favoured us with?—I gave you the three modes in which it was arrived at.

8072. You said that that was an experiment conducted by the late Mr. Keates, the chemist of the Metropolitan Board of Works, who unfortunately died a few months ago?—The experiment was conducted under the supervision of Mr. Keates.

8073. You yourself are not a chemist?—I am not.

8074. I will ask you to turn to page 961 of this Mud Inquiry volume, and I will draw your attention to Mr. Keates' own evidence. At the bottom of page 961 you find Question 10,080; the result is given. "That would reduce it to 26 grains," and the answer is "To about 26 grains." Now I invite your attention to this. The very gentleman who conducted the experiment says that the result of that experiment is not 57 grains, but 26?—I see that they have taken pretty well my own figures, but unfortunately they have not shown any determination as to the difference between the matter in solution in the sewage and in the effluent water; a part of the chemicals went away in solution in the effluent water.

8075. He did not know his business any better than the arbitrators?—I have given you his figures from his report, which show clearly that the quantity of suspended matter in this experiment was what I have stated, namely, 57 grains in the gallon.

8076. (*Chairman.*) Do you say that this experiment was not satisfactorily conducted by him?—The experiment was quite satisfactory, but the conclusions in the Mud Inquiry Report do not agree with the statements in the evidence. There was a certain amount of matter added to the sewage which went away in solution in the effluent; that is to say, the effluent contained a greater amount of matter in solution than the sewage originally did, and that ought to have been deducted.

8077. In their calculations they begin by adding the solid matter; that they do add, and then they omit to deduct that which went away in effluent?—Yes.

8078. That is your proposition?—Yes, those are the exact figures here.

(*Mr. Bidder.*) I thought it fair to draw the witness's attention to the fact that the gentleman who made the experiment had arrived at a different conclusion.

8079. (*Chairman.*) Does it appear in this evidence that any deduction had been made for the solid matter carried away in the effluent water?—That does not appear.

8080. And you say that some such deduction ought to have been made?—Certainly.

(*Chairman to Mr. Bidder.*) Do you say that it does appear that there was such a deduction?

8081. (*Mr. Bidder.*) I was going to ask a preliminary question. (*To the witness.*) Where does it appear that there was an increase of the matter in solution?—I have here a report of Mr. Keates, and on page 16 he gives the analysis of all samples of the sewage between August the 15th and the 30th of November; and the total solids in solution, if added up, and the average taken, show them to be 72 grains, and then the effluent water analyses are given by himself as 98·7. That is in the table on page 10 of the same Report, in the first column.

8082. (*Mr. Bidder.*) Where did you get the 72 grains?—At page 16 of Mr. Keates's report. By adding up all the solids in solution, and dividing the result by all the examples given there, it comes to 72.

8083. It is suggested to me that there were great variations, as the analyses show, in the quantities of the solids in solution, and that the figures you relied upon in the one case, do not relate to the same occasions as the figures you compare with them in the other case?—I presume Mr. Keates, in his report to the Metropolitan Board of Works, supplied this table showing what was the constituent of the raw sewage, and what was the constituent of the effluent, so I presume that he considered it a fair result to arrive at what was the effect of this process in the sewage.

(*Mr. Bidder.*) Let me refer your Lordship to the last page of the Report which the witness is referring to, which contains the analysis of raw sewage; your Lordship will see it gives about a dozen days, and the dates are given; this is on page 16, the last page of Mr. Keates's Report.

(*Witness.*) That column adds up to 864·4, and the average is 72.

8084. (*Mr. Bidder.*) Your Lordship will see that the analysis of raw sewage relates to about 12 occasions, the dates of which are given, beginning with August the 15th, and ending with November the 30th; the analysis of effluent sewage to compare with it will be found in the two previous pages, 14 and 15. Now, the first thing that these figures show is that the amount of solids in solutions varies very much?—It does.

8085. You have taken the effluents upon one day; at page 14 it is 90; it sinks to 79, and it rises to 145; that is enough to show a great amount of variation. Now, upon August the 15th we have not the corresponding analysis of the effluent water, therefore we cannot compare that. But upon August the 28th we have the amount of solids in solution as 74·9 in the raw sewage, and 90·3 in the effluent water?—Yes, showing the effluent water as containing the greater quantity.

8086. There is a difference there in favour of the effluent water, but nothing like so great as that which you mentioned; in fact, it is about 15 grains instead of 28. Now, on September the 9th we have the raw sewage, but we have not the effluent water. On September the 14th we have the raw sewage, but not the effluent water; upon October the 15th we have both.

(*Chairman.*) It does appear that the total solid matter in solution in the effluent water was greater than in the sewage.

(*Mr. Bidder.*) It does; I believe the chemists will agree that there is a certain excess, but not anything like what the witness has suggested.

(*Witness.*) I have only taken the figures from the Report.

8087. (*Mr. Bidder.*) I venture to suggest that you have compared things which are not comparable; you have compared raw sewage on one day with effluent on another day?—But, from what I understand from these experiments, the sewage was averaged, and Mr. Keates, in publishing these tables, gave what he considered to be the average quality of the sewage itself, and the same with regard to the effluent water; therefore, I consider that, if I take his results as I have done, it fairly gives these figures which I have already produced to the Commission.

(*Sir John Coode.*) Are those the experiments upon which Mr. Keates made the remark that the sewage at the southern outfall was abnormally weak throughout the whole experiment. I find that at page 10. If that relates to the same experiment, it would have a material bearing upon the point in question.

(*Mr. Bidder.*) The sewage upon the south side is always weaker than upon the north.

(*Sir John Coode.*) But Mr. Keates says, "With "respect to this point the sewage upon the south "side was abnormally weak throughout the whole "experiment," which would have a material bearing.

(*Witness.*) And at other times the amount of solid matter in solution would be very much more.

8088. (*Mr. Bidder.*) Let me now go to the other

*Mr. B. Latham, M. Inst. C.E.*

31 Jan. 1883

*Mr. B. Latham, M. Inst. C.E.*

31 Jan. 1883.

branch of the statement of the Referees in 1858 that the matter in suspension in the sewage is subject to a constant destructive decomposition; do you agree with that?—Yes, a certain portion of it; as I mentioned yesterday.

8089. To a very great extent that is true, is it not?—The chemists will tell you that.

8090. Suppose your figures which you gave yesterday were right, and that roundly 200,000 tons of suspended matter were annually projected into the river by the outfalls, have you any idea how much of that matter would be burnt up and destroyed by the destructive decomposition?—No; that is a matter beyond my province.

8091. You refer me to the chemists?—I do.

(*Sir John Coode.*) Let me refer you to page 125 of Messrs. Hawksley, Bidder, and Bazalgette's Report, on which is Table 13, in which you will see the extent to which the suspended matter varies according to the period of the day at which the sample was taken. Table 13 in Messrs. Hawksley, Bidder, and Bazalgette's Report shows that the total suspended matter from the samples taken at noon was 38·15 grains. Then, if you turn to Table 14, the samples of which were taken at midnight, you will see that the suspended matter scarcely touches 14 grains per gallon.

(*Mr. Michael.*) That is, giving the average between the samples.

(*Sir John Coode.*) But you must take care that the samples always are averaged.

(*Mr. Bidder.*) It must be remembered, in referring back to these tables, that in the sewers which are referred to there the sewage was much stronger than in the Metropolitan outfalls.

(*Sir John Coode.*) My remark only went to this, that we must have averaged results taken over periods of the day.

(*Mr. Bidder.*) I think you will find very valuable results in the Arbitrator's Report, and in the evidence in that book which is upon the table, because the subject was gone into in extreme minuteness on that occasion.

8092. (*Chairman.*) What is this destructive process which is referred to. It is not annihilation of the matter, but the resolution of it into its constituents?—Certainly, all the organic matter is capable of being oxidised and changed into different forms, carbonic acid, nitric acid, and so on.

8093. Changed into its constituents, it would be no longer solid then?—No, it would be changed and go away in the water.

8094. It would be no longer capable of depositing itself?—That part which is mineral, such as the road detritus, would be capable of forming sand in the bed of the river.

8095. Would the strictly organic matter, though no longer capable of depositing, be capable of poisoning the water?—Yes, it is that which in hot weather really causes the water and the mud-banks to be so offensive. In the course of decomposition, certain parts of the constituents of the mud-banks are given off in a gaseous form and pass into the water.

8096. (*Mr. Bidder.*) And as matter in suspension ceases to exist?—I was speaking of the mud-bank, which was not matter in suspension.

8097. However, you refer me to the chemists as to what matter disappears as matter in suspension?—Yes, I have not myself made any experiments in the Thames mud, but I know that the chemists have, both upon your side and upon our side; therefore they are the competent parties to speak to it.

8098. You gave a confirmatory calculation yesterday, based upon the assumption that every unit of the population produced, I think you said, 3½ ounces per diem of solid matter contributed to the sewage?—Yes.

8099. Are you aware that that 3½ ounces,—I do not know where you got it from; it is not a recognized figure—represents moist fæces and not dry fæces?—I beg your pardon, it does not at all.

8100. I am told so by a chemist; is it not the fact that that figure represents matter which contains 75 per cent. of water?—No, certainly not.

(*Dr. de Chaumont.*) I put that question to Mr. Latham yesterday, and he distinctly says it represents water-free substance.

(*Witness.*) I stated also that that included the total matter in solution, both in the urine and fæces.

8101. (*Mr. Bidder.*) Your calculation is based upon the assumption that there is that amount of solid water-free matter?—Upon the understanding that that amount in solution was made up by other substances which were added to the sewage.

8102. That is another point; but your basis of calculation is founded first upon this, that each unit of the population contributes in suspension and solution what is equivalent to 3½ ounces of solid water-free matter?—Yes, but with no view of saying that that contains nothing that was not suspended matter in the sewage.

8103. (*Chairman.*) Take the excreta of a man for a day, and dry it thoroughly, so that there was no moisture in it, would that be 3½ ounces?—The excreta and the urine, taking the average of the whole population. But, taking a man alone, it would be more. A man's excreta upon the whole would, it is calculated, amount to one quarter of a pound of fæces in a moist state.

8104. Not including the urine in that case?—No.

8105. Is there solid matter in the urine when it is dried?—Yes.

8106. (*Mr. Bidder.*) I want to see if we correctly understand the basis. You mean that if the entire excreta of a man had all the water evaporated from them they would weigh 3½ ounces?—I do not say of a man; I say the whole of a mixed population, men, children, and women, more or less.

8107. That is your basis; that the entire excreta of an average unit of the population, when evaporated, so that they would contain no moisture, would weigh upon the average 3½ ounces?—Yes.

8108. Passing from that to the inference with regard to the amount of suspended matter, before you can apply that in any way to the amount of the suspended matter in the sewage, you must have some knowledge as to the proportion of that 3½ ounces which would represent matter in suspension and matter in solution originally?—Yes.

8109. Have you any information to give to the Commission as to that point?—I do not think I have the figures; but in one of the reports of the Commissioners you will find them fully set out. Those are of course things which I do not know from actual experiment, it is only a matter which I have become acquainted with in the course of my profession; but from the same source from which I have got it I can provide you with the quantity.

8110. Have you made any assumption upon that quantity in your calculation?—I have already said that I base nothing whatever upon that fact.

8111. Suppose, for instance, the fact be, as I am told it is, that of the total solids obtained in that way, whether it is 3½ ounces or any other quantity, four-fifths represents the matter in solution and one-fifth represents the matter in suspension; does not that very seriously affect the amount of matter in suspension that you get?—Of course, if that is so.

8112. If that is so, would it not seriously affect the question?—But it is nothing like that; there is four-fifths of the total nitrogen in the urine in solution, but that would not be true with regard to the solids.

8113. Where did you get your 3½ ounces from; of course, as an engineer, it is not from your own observation?—I cannot tell you, it is information which I have come across.

8114. You cannot refer me to any documentary authority on that point?—In a great number of places I believe it is quoted; it is in the Report of Mr. Cuthbert Johnson to the Commissioners of

Sewers; then there was the evidence given before the Select Committee of 1858, when Dr. Thompson went very largely into that question. I have a note to this effect—"Report of Select Committee on River "Thames, July 1858, Evidence of Dr. L. Thompson, "Question 1691. Each individual contributes at the "rate of 3½ ounces per diem."

8115. But contributes what?—Solid matter.

(*Chairman to Mr. Bidder.*) I have no doubt it is subject to correction and better information, but, in the opinion of one member of the Commission, that is about the contribution of each average individual.

(*Mr. Bidder.*) I am told that that is about the contribution of moist fœces, of which 75 per cent. is water; but I think it would be a saving of time if I were to leave that till the chemists come into the box. Mr. Latham says it is not an observation of his own, and, having got what his observation is, I will leave it there.

(*Witness.*) I find that the same eminent chemist, Dr. L. Thompson, in the same inquiry, estimated the solid matter of the sewage then at 260 tons a day; that is at Question 1671.

(*Mr. Bidder.*) I will pass from that I have got clearly from you what your basis is, and I shall not profitably occupy time by carrying it further. It comes to this, as far as you are concerned, that your figures are taken upon a basis, and you have explained to us that you do not undertake to say what the proportion of sewage destroyed as matter in suspension by decomposition is. Beyond that, have you any knowledge of your own of what the proportion is between what is dry and what is moist?

(*Sir P. Benson Maxwell.*) I understood the witness to say that he gave you certain results from the Native Guano Company's experiments, and then he said, if you will assume that 3½ ounces is the ordinary amount that is generally recognized by men of science, then you will find that my calculation from the Native Guano Company's process is very much confirmed by the calculations upon that estimate.

(*Mr. Bidder.*) My question is whether it does confirm it or not; and that depends upon whether it is dry or moist, or a mixture of the two.

(*Chairman.*) The calculations of the men of science show what ought to be the result of the experiment, and the result of the experiment was that.

(*Mr. Bidder.*) But there is also a question behind; supposing the figures are right in the beginning, how much of that, or what proportion, is destroyed by chemical decomposition?

(*Chairman.*) Made to cease to exist as organic matter?

(*Mr. Bidder.*) No, as matter in suspension; that it becomes soluble matter, or gas.

(*Witness.*) I gave another estimate of the amount of solid matter which is drawn from the experiments which I mentioned as being made at Croydon, and that was, that it was one-fifth of a pound per head per day. The 3½ ounces does mean matter in suspension, but is only given as a matter of comparison with the figures I gave from the ABC experiment, and also to compare with the one-fifth of a pound per head, which, I say, is a very fair estimate of the amount of solid matter contributed by the population to the sewers.

8116. (*Mr. Bidder.*) Now, passing from that, you told me that 13 grains of chlorine was an unusual amount of chlorine to find in chalk water, upon the average?—I said in an inland place.

8117. I draw your attention to the Sixth Report of the Rivers Pollution Commission of 1874, and on page 104 of that Report is a Table in which they give the composition of water in deep wells in the chalk beneath the London clay, and they give an analysis of the water in wells in different parts of the country, and they give the quantity of the chlorine, and they show an average of 15, which is rather more than yours. Taking those results, it would show that your well at Grays was rather freer of chlorine than the average of the unpolluted water of the district?—I should like to say, with regard to that, that those you are referring to are a totally different character of water from those of ordinary chalk wells; in every one of those instances the chalk is overlaid by other geological formations, and, whenever that is the case, it makes a very considerable difference to the quality of the water. But if you go to absolute chalk wells where there is no other geological formation except the chalk or the Thanet sand overlying it, then I say that, with the exception of places liable to be infected by sea-water or tidal water, you will not find such a quantity of chlorine in any instance.

8118. But at Grays that chalk is fed by water from chalk hills, north and south, a great many miles of which are overlaid by that stratification?—Let me point this out, having studied this area very carefully. I find at New Wimbledon a bore-hole mentioned. Now it is a fact that the chalk in that district is absolutely devoid of water; the water comes from the Thanet sand and the Woolwich and Reading beds overlying the chalk, and by infiltration from the Wandle itself. I can show you that all the wells in the district of the Wandle valley are supplied by waters that infiltrate, and are not the natural water of the district itself.

8119. But you know the Wandle itself is chalk water?—Yes; but I know that the Wandle and the waters which are supplied from the strata overlying the chalk are not so pure as the real chalk water.

8120. But in this Report they give this as a fair example of unpolluted waters from deep wells from chalk beneath the London clay?—Yes; but I say that it has been investigated over and over again by chemists and found that whenever the chalk is covered by London clay, the water differs essentially from the pure chalk water.

8121. But the London clay, if I am not mistaken, though it may not overlie the Grays quarries, yet overlies the district all round. Let me now draw your attention to the fact that the very worst well in this list is the well at Braintree, in Essex?—Yes, it is a very deep well, and a very deep well under those conditions which I have already pointed out, so that the water differs essentially from the chalk water in these wells.

8122. Am I not right in this, that the London clay overlies the chalk in that part of the river?—In the case of Braintree there is a considerable depth of clay overlying the chalk.

8123. Will you kindly follow my question? Am I not right in saying that in the district in Essex, in the neighbourhood of Grays to the north, the London clay overlies the chalk?—Yes, certainly, in part of it.

8124. And within less than a mile of the well itself?—I cannot say that, but you had Mr. Whitaker here, and he told you the exact geological formation of the district. I may say that there is a list of chalk wells at page 132 of the Sixth Report of the Rivers Pollution Commission, and there is not one of them which has the amount of chlorine which is shown by the Grays water, and the waters at Grays, before being exhaustively pumped, yielded a very small amount of chlorine.

8125. Now, going on to another matter. You gave a good deal of evidence about the design of the Metropolitan main sewers, and as to what they were provided for as compared to what they have to do. I will not attempt to follow it out in detail, but I will ask you one or two principal matters. You said that the western district was not intended to be provided for by these sewers, and was afterwards taken in; that was the purport of your evidence?—I read paragraphs from several Reports of the Metropolitan Board of Works, showing to my mind that that was the case.

8126. Are you aware that the sewers were afterwards enlarged distinctly to accommodate the western district?—I have already distinctly pointed out that it could not be so, because from the dates of the Reports the northern outfall was more than half completed at a time when the Metropolitan Board of

*Mr. B. Latham, M. Inst. C.E.*

31 Jan. 1883.

Works had not determined to take the sewage of the western district to Barking; it is quite clear that the low-level sewer was enlarged from 9 feet to 10 feet 3, but not the northern outfall.

(*Chairman.*) This is a matter upon which there can be no doubt; it is not a matter of opinion. Sir Joseph Bazalgette can tell us how it was. If he does say that they were enlarged, then your speculations are erroneous.

(*Witness.*) Then the Metropolitan Board of Works' Reports are erroneous, for I am taking my statement from the actual Reports published by them.

(*Mr. Bidder.*) My learned friend and myself thought it would be better not to follow all that part of the witness's evidence out in detail, but let Sir Joseph Bazalgette deal with it when he comes before you.

(*Mr. Lumley Smith.*) It is convenient for my learned friend to indicate the matters upon which he will contest our evidence.

(*Chairman.*) This is scarcely a matter of opinion. All that you are called upon to do is this; Sir Joseph Bazalgette will say you are wrong in your conclusion. In the face of that, are you prepared to abide by it?

8127. (*Mr. Bidder to the witness.*) In regard to the population, are you aware that you have made a mistake in the population, and that you have counted part of it twice over?—Which part.

8128. I will refer you to it

(*Chairman.*) That is a point which you ought to go into and show which part.

8129. (*Mr. Bidder.*) I cannot lay my hand upon it at the moment, but let me ask you in the meanwhile another question upon the deductions drawn from the Croydon observations. Besides the observation I threw out at the time as to what happens upon a particular spot not happening upon the whole area at the same time, is not there this element also in comparing a great area with a small one; that, even where you have a certain amount of rainfall over a whole area, where it is a very large area the distances of certain parts of the area from the outfall are so different that the flow is spread over a longer time. In the case of London, for example, the eastern part of London is within three or four miles of Barking, while the western extremity of the district is more like 16 or 17 miles, and consequently, supposing you have a shower over the whole district at once of a tenth of an inch, the eastern part has been got rid of long before the western part comes upon the back of the sewer: is not that true?—Yes, that is so; but I have only dealt with the figures you have given us with regard to the carrying capacity of the sewers.

8130. Supposing that at Croydon you observe that a certain amount of rainfall trebled or quadrupled the flow in the sewer, and supposing all the other circumstances were exactly applicable to the greater case of the metropolis, yet owing to the circumstance that in one case the rainfall flows off in a few minutes and in the other it takes a longer time to flow off, the same results will not necessarily follow?—But I should point out that this length of sewer in the same way equalises the flow of the sewage itself in the sewers, and that, therefore, at the minimum period of flow in the day there is more sewage in the sewers than is due to that period, and, therefore, there is not so much room for the rainfall.

(*Mr. Bidder.*) One can imagine circumstances in which, if it rained at each part of the metropolitan area exactly at the proper time, then you would have all the sewers congested at the same moment.

(*Chairman.*) Another thing, I suppose, is that as the sewers get to a distance from their outlet they are smaller in their carrying capacity, are they not.

8131. (*Mr. Bidder.*) Yes, they are. (*To the witness.*) So it does not follow because at Croydon a certain amount of rain will treble or quadruple the amount of water in the sewers, that even under the same circumstances the same thing would happen in the metropolis?—I have already told you that in the south it would only have to be 2·76 times the mean flow, and then there would be an overflow all along the lines; and the same thing applies to any part of the district separately, because this is an aggregation of a number of districts.

8132. Will you kindly follow the question. Is it not the case that owing to the circumstances I have referred to, it does not follow because at Croydon one tenth of an inch will produce a quadrupling of the flow of the sewer, that under the same circumstance the whole of the metropolis would be quadrupled as to the flow in the sewers?—I say it would produce a larger effect, because in the metropolis the whole of the rain goes into the sewers, whereas in Croydon the greater part is excluded; therefore, if you ask me to compare the two things, I say that the fluctuation is likely to be greater in the metropolis than it is at Croydon.

8133. It is quite true to say that there may be elements in the London sewers which would tend to aggravate the point, but it would not follow that because at Croydon one tenth of an inch would produce a quadrupling of the flow of the sewer, the sewage flow over the whole of the metropolis would be quadrupled in the same way?—I can see no difference whatever, because it is necessary to provide each one of those districts with overflows, which has the effect virtually of dividing the metropolis into so many small districts; and, therefore, when any one of those overflows comes into operation it has the effect of separating that district and bringing it under the same conditions as Croydon.

8134. I now go to what I gather has been your principal occupation, and that which you present as the result of your investigation, namely, this report and these voluminous plans and diagrams which you have laid before the Commission. I think those are the principal things which have occupied your attention for the last year?—They are part of the subject which has occupied my attention, but I cannot say that they are the principal things.

8135. I may take it that this being your report it contains what you consider the most important of your views, and of those who are represented on the other side of the table?—That contains our observations.

8136. Upon which you mainly rely?—We do not rely alone upon them.

8137. Is the material supplied in this book and these diagrams material to the inquiry; does it support your case or not?—Certainly it does; it corroborates the other parts of the evidence with regard to the state of the tides.

8138. As I understand, the purport of it is that the sewage apart from the mixing action remains in the river oscillating backwards and forwards for a time, very much longer than the Metropolitan Board of Works say?—We do not say anything about it; we say that it shows the oscillation of the tides, and that wherever those floats have gone sewage may go.

8139. Does not that show that the sewage oscillating up and down remains in the river very much longer than we say it does?—It is confirmatory of the observation that sewage will go wherever the floats go, and you will find with regard to the question of chlorine in the water, that a float has never gone except where there has been sea-water, and, therefore, this is really to test the range of the tide.

8140. I suppose, in fact, we all know that the tide in the Thames is at high water at different times at different parts of the river; that is to say, London Bridge is always a certain number of minutes after Greenwich, and Teddington is a certain time after London Bridge, and so on?—That is so.

8141. How long is the interval between high-water at London Bridge and high-water at Teddington?—Captain Burstal published a table a few months ago showing the high-water all the way down the river; it is one hour and a half from the Nore Light to London Bridge, and it is one hour and twenty minutes from London Bridge to Teddington.

8142. (*Chairman.*) It is nearly three hours from the Nore to Teddington?—Yes.

8143. (*Mr. Bidder.*) So that Teddington high water is one hour and a half after high water at London Bridge?—High water at Teddington is an hour and 20 minutes after high water at London Bridge.

8144. Then we can draw any approximate conclusions as to intermediate places?—Yes.

8145. Let me draw your attention to page 38 of your report; you show there that the duration of a whole tide at Teddington is 12 hours and 13 minutes, the duration at parts lower down the river being 12 hours and 25 minutes. If those observations are correct, the duration of the tide at Teddington is 12 minutes less than at London Bridge and Deptford?—I explained that the exact time of the tide at Teddington was a very difficult matter to arrive at with regard to the time of the tide.

8146. Will you kindly answer the question?—I pointed out that there is a period in which you cannot ascertain really whether it is high water or low water. Those are the exact results of the measurements, without any correction, you may say that it ought to have been 12 hours 24 minutes or 12 hours 25 minutes. I say that there is a period, when you are scaling them off upon the diagram, when it is impossible to ascertain it with certainty at Teddington.

8147. Therefore it is an error?—It is an error to that extent.

8148. (*Chairman.*) To what extent is it an error?—Those are the results of scaling from the diagrams, and whatever they scale, those are the results; but it is a very difficult matter at Teddington to do it, because the top of the tidal wave only is recorded, and you will get a confusion in the tides at this point. There must naturally be the same period of tidal flow all the way up the river. Those are the measurements from the diagram, but these are the measurements all the way up the river (*pointing to the diagram*).

8149. (*Mr. Bidder.*) If you say it is wrong, I will pass from it?—It is not correct to that extent.

8150. (*Sir John Coode.*) I think what the witness means to say is that the development of the time of high water is not so marked at Teddington as it is further down the river?—Yes.

8151. And for that reason it is not possible to ascertain so accurately the moment of high water at Teddington as in the lower parts of the river?—And of low water as well.

(*Chairman.*) What you mean to say is that it is not not so much that it is wrong, as that it must be wrong.

8152. (*Mr. Bidder.*) If high water at Teddington is always an hour and a half after London Bridge, according to these figures, there must be a difference in the tidal wave?—I explained at the time the reason for it.

8153. (*Chairman.*) You did not adopt my suggestion, but, may we take it, that it cannot be right?—We know that the time of the tides cannot be different.

8154. How do you mean?—If I had chosen to take a particular length, and made every day a tidal day instead of scaling them off as we have done, and giving you the exact result by the scale, we could very soon have put in that 12 hours 25 minutes, as it must be all the way down the river. It is not that the observations are in error, but that the computations do not quite tally (*explaining the diagram to the Commissioners*). We have taken in the measurements, the exact scaling of the diagrams, and added them all together.

8155. (*Sir John Coode.*) If you scaled your diagram, why did you not take the records as they were actually observed?—We have taken the records as they were actually observed, but it is difficult to measure both the points of high water and low water at Teddington.

9156. (*Mr. Bidder.*) Now, I pass to what is more important matter in this report. On the same occasion you have given a table with the figures of the results of those floats, which represents in figures what you have represented more graphically in the diagrams?—That is so.

8157. I am not going to take each individually and follow it, but you have given something like six weeks as the duration of your experiments for these floats?—Yes.

8158. And at the bottom of the table you have given the average performance of that float during six weeks?—The average of the column of figures.

8159. Then you have divided that into morning tides and afternoon tides?—Yes, I have.

8160. Just to make that clear a little bit, because the tide is shifting every day; what do you class as a morning tide, and what do you class as an afternoon tide, because, of course, the tide at high water shifts day by day?—As a morning tide, I class any tide of which the largest part is between 12 at midnight and 12 at noon, and as an afternoon tide I class any tide of which the largest part is between 12 o'clock at noon and 12 at midnight.

8161. (*Chairman.*) If it were high tide now (2.30 p.m.) what would you call it?—A morning tide; but if you see where it crosses the line at 12 at night if the biggest part of it were before midnight, that would be put down as an afternoon tide, and if the biggest part of it occurred in the morning, that would be put down as a morning tide.

8162. (*Mr. Bidder.*) Take high water 1 o'clock in the afternoon, is that a morning or an afternoon tide?—1 o'clock would be a morning tide, because the biggest part of it is in the morning.

8163. High water at 2 o'clock would be a morning tide?—Yes.

8164. Up to 3 o'clock it would be a morning tide?—Yes.

8165. And high water at 4 o'clock would be an afternoon tide?—Yes.

8166. And so up to 6 and 7 and 8 and 9 in the evening up to midnight would all be afternoon tides?—Yes.

8167. Then in point of fact, it comes to this: That whenever the greatest amount of flow is in the afternoon period, it goes into that period of the day, and whenever the greatest amount of flow is in the other period of the day, it goes into the morning period?—Yes.

8168. Where the tide is between 3 in the morning and 3 in the afternoon, it is a morning tide, and when the tide is between 3 in the afternoon and 3 in the morning, it is an afternoon tide?—That is so.

8169. Now to take Float No. 1. I see that of Float No. 1 the average performance was this: that upon the morning tides it went down 12½ miles, and came up 12·26 per diem, so that it went a quarter of a mile down the river every morning tide, upon the average; is not that right?—On an average tide.

8170. Upon the morning tide?—Yes.

8171. For the average of the whole six weeks morning tides, it went down to a quarter of a mile?—Yes.

8172. On afternoon tides it went down 13·09 miles and went up 13·24 miles, so that upon the afternoon tides it went up instead of down a fifth of a mile upon each tide?—Yes.

8173. How can you explain rationally the fact that the difference between the morning and afternoon tide should make a difference between going up and down the river?—I say that the whole range of the tides in this particular period is greater; there is a diurnal difference in the period of the tide, which is greater in the afternoon.

8174. Supposing that there is a diurnal difference, which makes the afternoon tide stronger than the other, do you suggest ——?—The greater impulse would occur upon the flood tide only, and therefore it would affect that particular tide.

8175. Do you believe it is the fact that the morning tides of the river Thames are a quarter of a mile stronger upon the ebb, while the afternoon tides are

*Mr. B. Latham, M. Inst. C.E.*

3 Jan. 1883.

quarter of a mile stronger upon the flood?—Yes, at this particular period of the year; in the summer-time they change about the other way.

8176. Have you any authority for this suggestion as to the preponderance of strength in the afternoon flood and morning ebb tides?—I have already told you that this diurnal fluctuation in the flow of the tides affects the afternoon tides in the winter, and in summer it affects the morning tides.

8177. (*Chairman.*) Is this recognised?—Yes, it is a well-known fact; it is due to the position of the earth with regard to the sun.

8178. (*Mr. Bidder.*) I am quite aware that there is what is known to astronomers as a diurnal variation in the tide, but that is a variation in the height of the tide?—But whatever varies the height must vary the velocity of flow to increase that height.

8179. Both on flood and ebb?—Yes; but more on the flood; as I have already pointed out to you the velocity of the flood tide is very much more than that of the ebb tide.

8180. Does not the question whether upon the whole tide the balance of progress is down or not depend upon this, whether the amount of land water which is coming over Teddington Weir, and the other tributaries in the interval, is not an excess quantity over and above what is required in the case of spring tides to make up the increase of the tide?—I say that the amount of land water has nothing whatever to do with this question of tidal oscillation.

8181. (*Chairman.*) Supposing we got a place where there was no land water, no back water of any kind—take, if you like, the coast at Brighton; do you mean that the afternoon tides, as you call them, rise higher than the morning tides?—Yes, at this period of the year; and in the summer time it is just the reverse; then the morning tides are the most affected.

8182. The afternoon tides rise higher you say than the morning tides?—Yes, at this period of the year.

8183. Do not they also fall lower?—There is a greater range of tides altogether, and whenever they rise higher they fall lower.

8184. Then I do not see why your log should have made a voyage up the river?—For this reason, that there is a greater difference of proportionate velocity between the flood and ebb tide.

8185. (*Mr. Bidder.*) Suppose at Brighton you had an estuary running inland, into which no tributary water ran of any kind, but which was simply filled and emptied by the efflux and influx of the tide, if the tide rose higher more water would come in?—Yes.

8186. And more water would go out upon the ebb?—Certainly.

8187. And at the end of the 12 hours there would be the same water left in the inlet as at the beginning?—And there might be less.

8188. But upon the average extending over two or three lunations it would be the same?—It might be.

8189. Otherwise let me ask you if it is true upon that one observation that the two tides if we combine them together have almost exactly neutralised each other?—Yes; I say that there is nothing in this table to which you have drawn attention which is contrary to what is known with regard to the movement of tidal water.

(*Chairman.*) Supposing there has been some inaccuracy in the observation of these logs; supposing sometimes when the tide was going down they got stranded, and when they were going up they never got stranded, does not, after all, the witness's table show that the water (I will not say sewage, because it might hurt your feelings) is oscillating there somewhat in the way he describes.

(*Mr. Bidder.*) Nobody disputes that sewage oscillates; that is admitted by everybody.

(*Chairman.*) It may be wrong to say that the log or float ever could have got higher than the point it started from at the end of a month's journey even, but supposing it were a mile short of that, do you see what I mean.

(*Mr. Bidder.*) I see what your lordship means, but assuming, as I am bound to assume, that this report has some relevance to the case, the matter is not a question of principle affirmatively whether there is oscillation or not, because nobody doubts that, nobody pretends that the sewage goes straight away to the sea upon the same tide as that upon which it is poured in, but it is a matter of degree.

(*Chairman.*) As I understand the effect of these experiments is that the sewage oscillates about in the river without ever going down at all until floods come.

(*Mr Bidder.*) That it remains in the river four or five times as long as we believe it does.

(*Chairman.*) It is not a minute question, but a substantial question.

(*Mr. Bidder.*) Yes, turning upon questions of figures which possibly at the first glance might appear to be minute.

(*Chairman.*) What would carry the log out to sea is the fresh water which is introduced into the river.

(*Mr. Bidder.*) The preponderance of it.

(*Chairman.*) I asked the witness on the last occasion, and I think he could not answer me, whether the downward progression of his floats was proportionate to or corresponded with the total bulk of the river water that was introduced.

(*Mr. Bidder.*) I am going to deal with that; but meanwhile, as to the question of whether it is a minute difference between us. Minute is a relative term, and when I tell you what our views are, you will be better able to judge whether it is minute or not. We do not suggest that the sewage goes down in its progress seaward more than half a mile a day after the return tide, that is, apart from the mixing action, that the mere effect of the land water upon the average would not take it more than half a mile a day out.

(*Chairman.*) That is to say a float would go down at the rate of half a mile a day.

(*Mr. Bidder.*) If you could have a float which would truly represent the average of the river, that would be all you would get.

(*Chairman.*) Would you accept that?

(*Witness.*) The question of oscillation is totally distinct from that of progression. We have put the matter much more favourably, because the moment we put the mixing action before you we show that the sewage goes out much more quickly than it was formerly supposed to go, when it was only supposed to move by displacement. Mixing is much in excess of ordinary displacement.

8190. (*Chairman.*) Would you accept the concession that the float would go down at the rate of half a mile a day?—No, I do not accept that because I go by what the floats have done. I have already stated in this report that in the original experiment made by the Metropolitan Board of Works, taking the result of their floats, and the average of their period of experiment, their float only went down one third of a mile.

(*Sir P. Benson-Maxwell.*) You made it one twenty-fifth of a mile.

(*Mr. Bidder.*) I want to satisfy the Commission that all this is absolutely worthless. I say plainly what I am driving at now, that these observations are not worth the paper they are written upon from beginning to end.

(*Witness.*) It is singular that you should have thought them of so much importance as to have them all checked by having floats out and men checking them.

(*Mr. Bidder.*) I say boldly that I challenge the whole lot of observations as absolutely worthless.

(*Chairman.*) Do you mean as being erroneous or as proving nothing?

(*Mr. Bidder.*) Both my lord. I am not suggesting that anybody has purposely vitiated them; but that whether by carelessness or by ignorance the whole set of observations is utterly and absolutely worthless.

(*Witness.*) That is only an assertion. Perhaps you will point out where they are erroneous.

(*Mr. Bidder.*) Now let me ask you to take into your hand a diagram we have prepared which purports to represent what happened simultaneously to No. 2 and No. 3 floats, and I will ask you to check it by your tables and tell me whether it is accurate. This is diagram A (*handing the same to the witness**) showing contradictory results in the float experiment. The full line coloured red shows the progress made up the river by Float No. 3 in five tides, commencing at high water September 18th, 1882, the dotted line coloured yellow shows the progress down the river made by the same float during the same times, and commencing at Greenwich. I invite you to check that by your own observations and diagrams, and tell us whether that correctly represents the results of observations during the same time. That shows where it was at the beginning of the first tide, and where it was at the end of the fifth. One had gone up the river two and three quarter miles whilst the other had been going down the river four and three quarter miles. That is the result of five successive tides.

(*Chairman.*) At the same two hours or three hours, or what not, the floats are going different ways in the river.

(*Mr. Bidder.*) Not two hours or three hours, but for five successive tides. that is 60 odd hours, starting at the same moment.

(*Witness.*) That can easily be accounted for. It is quite a well understood thing for the tide to be running two ways in the river at the same time, it begins to run out at the mouth before it has ceased running up at the top. If your engineers have corrected it I must take it from you, I have now no opportunity of doing it.

(*Mr. Bidder.*) Float No. 2, upon the 18th of September was, according to the diagram, opposite to Greenwich Station at high-water, at a mileage of $6\frac{3}{4}$ miles. Now, if you take the fifth tide afterwards, you will see that it was at Woolwich station at two miles, showing that it had gone down $4\frac{3}{4}$ miles; therefore that establishes the accuracy of the diagram I have put in as far as Float No. 2 is concerned. Now, if you take Float No. 3 upon the same day, you will see that upon the 18th of September it was at Lambeth Bridge at 14 miles, and five tides further on it was opposite Chelsea Bridge at $16\frac{1}{2}$ miles; so that it had gone up practically $2\frac{1}{2}$ miles, while the other had been going down $4\frac{3}{4}$ miles. That is the fact. Now will you give us any explanation you like.

(*Chairman.*) It comes to this; that the float at Lambeth Bridge in five tides makes $2\frac{1}{2}$ miles up the river, while upon the same five tides the float at Greenwich makes $4\frac{1}{2}$ miles down the river.

(*The witness examined his diagram.*)

(*Mr. Bidder.*) If you have nothing to say as to that for the moment I will ask you to go to another diagram marked B. I will ask you to go to Nos. 4 and 5 Floats, which were also taken simultaneously.

(*Chairman to Mr. Bidder.*) Do you say that after a time those two floats behave as they ought to do, so to speak; do they get right again in relation to each other?

(*Mr. Bidder.*) I can believe them to be capable of doing anything. There is no law that they observe.

(*Witness.*) If you observe upon the 23rd of September the general tendency is downwards in them all; they follow the range of the tide.

8191. (*Mr. Bidder.*) That is upwards? — Yes. There may have been no end of accidental circumstances which may have interfered with a particular float for a short time, especially in that higher part of the river where the river is shallow.

8192. We will go to lower down the river. You have now the diagram of Nos. 4 and 5, and that in the same way shows that in three successive tides No. 5 went up the river, No. 5 being at Greenwich, the same place as the float distinguished itself in the last case by going down so much. No. 5 went up the river just under a mile, whilst No. 4, a little lower down, went down the river nearly four miles?—That corroborates the accuracy of the other two floats, which were put in at exactly corresponding periods of the tide. No. 2 was put in at half tide, and No. 5 was put in at half tide.

8193. What rational suggestion can you make for the river at Greenwich flowing up upon the average of three tides, whilst the river at Woolwich flowed down? — Because there may be certain differences with regard to the shape of the river, and the direction of the wind in particular places which may affect the floats.

8194. Where did the water come from between Greenwich and Woolwich which supplied the preponderating influence? — But the floats may be effected by wind as well as by water; so that there is nothing in that.

8195. That is what I was to come to; that the float is effected by wind as well as by water?—But at the same time that does not detract from the importance of the fact that wherever the float is found there sewage will be found.

(*Chairman to Mr. Bidder.*) When the float is represented as going up the river, that of course is with a rising tide.

(*Mr. Bidder.*) It must have gone up upon the flowing tide.

(*Chairman.*) The witness never represents the float as going down the river at that time, does he?

(*Mr. Bidder.*) No; but what we are talking of is not the actual motion, but the balance of motion.

(*Sir John Coode.*) Not necessarily.

(*Mr. Bidder.*) If it is towed by the boat, or if it has grounded then there may be a tendency to go in another direction.

(*Chairman.*) I gather that one float in the course of a 12 hours tide up and down, has made upward way to a certain extent, while another float in the course of the same tide up and down has made downward way.

(*Witness.*) That is so; but the floats are in a different part of the river. The diagrams which have been put in show that they are in different parts of the river.

(*Mr. Bidder.*) I would venture to say that that does not account for it. In point of fact you must not accept that as the fact, because what the diagrams shows is the position of the float at the beginning and at the end of the experiment.

(*Witness.*) You will observe as to both No. 3 and No. 5, which are floats which are put in at half ebb, that one corroborates the other; they both went up.

(*Mr. Bidder.*) No, they did not.

(*Witness.*) According to your diagram which you have just put in, they do.

8196. (*Mr. Bidder.*) No. 5, which is the former in the upward direction in the last diagram, is in the very part of the river where preponderance was downward in the previous one. Now I will take another date, the 29th of September. This diagram is labelled C (*handing the same to the witness*). This shows, and I invite you to say if it is inaccurate, that No. 2 in two tides went up three miles, whilst at the very same time No. 4 went down four and a quarter miles? —That exactly corroborates the same thing with regard to the other floats, and they were all watched by different observers, therefore it is utterly impossible for there to be such a collusion as you would suggest, and that these are in error, for these floats are corroborated one by the other. I say that is the real true progress made by the floats in one part of the river and in another.

8197. I did not suggest any collusion?—I think you suggested on the last occasion that the floats were anchored at night.

(*Mr Bidder.*) I did suggest that those floats were very difficult things to keep sight of at night, and that it was quite possible that the float might have

* The diagrams put to the witness by the cross-examining counsel will be put in at a future time.

been attached to the stern of the boat. Our floats had lamps upon them, but theirs had not. Now take the D diagram (*handing the same to the witness*). No. 2 float and No. 7 float started very near together, about a mile and a half off each other, and No. 2 float, the yellow one, in 15 tides had moved up the river a mile and a quarter, whereas float No. 7 had gone up the river 10½ miles in the very same time; that is to say, one had started a mile and a half above the other, and left off about 10 or 11 miles ahead of it. What do you say to that. That is commencing at high water October 6th, on which date Float No, 7 was at six miles, being just below Greenwich station; now if you look on to October the 14th it was 16½ miles, opposite old Chelsea bridge so that it had gone up 10½ miles.

(*Chairman.*) But where had the other gone upon the 16th.

(*Mr. Bidder.*) On October the 16th it was at Angerstein's wharf, four miles, and upon the 14th it was opposite the West India Dock, mileage 5¼. I think that corroborates the figures given in the diagram. You will find one went a mile and a quarter up, and the other went ten and a half miles, and yet they started exactly two miles apart; and you will remember that they had been oscillating up and down the same parts of the river. Having drawn your attention to that will you now refer to diagram E (*handing a diagram to the witness*). In the last case, as Sir John Coode will see, the one float starting two miles higher up the river than the other, gained nine miles upon it. Now I take a case where exactly the opposite thing happened. In this diagram E, which is before the Commission, in two tides from the 16th of October 1882, Float No. 1, which started at Crossness, went up 8½ miles, while No. 2, which started at Greenwich, and therefore ought to have done a great deal better, went up only a mile and a half, in fact within 24 hours, the lower Float gained seven miles upon the upper one.

(*Witness.*) That would be affected by the amount of land water coming down then.

8198. How did the land-water stop the first, and escape the other down below it?—For the simple reason that the land-water has less effect in the lower part of the river; the higher it is up, the more it will affect the float.

8199. They had been practically in the same part of the river, because you must recollect they are oscillating up and down.

(*Sir John Coode to Mr. Bidder.*) There is one thing I have to call attention to, and that is that upon the 16th there are 116,000 cubic feet of water coming down, and upon the 17th there are 288,000 cubic feet, therefore that quantity of water would be tending to carry the float further down.

(*Mr. Bidder.*) But why should it stop one and not the other, being, as they were, in the same part of the river.

(*Sir John Coode.*) But the impulse is very much greater in the narrower part of the river.

(*Mr Bidder.*) But where they leave off the lower float is not a mile and a half distant from the other.

(*Sir John Coode.*) Because in the mean time probably the flood tide has come up and overridden the water coming down from Teddington Weir.

(*Mr. Bidder.*) But these floats have been twice up and down in the same part of the river, and let me draw attention also to this; that the flood water is not strong, for both those floats are making their way up the river; they are not being borne down by the flood water.

(*Chairman.*) What Sir John Coode says is that the higher you go up the river the greater the power of the up-land water to stop the rising tide.

(*Mr. Bidder.*) If that is the cause which has produced this extraordinary difference of seven miles in neighbouring parts of the river; there must have been a very strong land-water, and how do you account for both the floats going up the river in the face of that land water?

(*Sir John Coode.*) But you must not forget the relative sectional areas of the river at the different points.

(*Chairman.*) I should think no amount of land-water is operative at Sheerness for example.

(*Witness.*) That is so.

(*Chairman.*) Then the lower you go the greater the sectional area, as Sir John Coode says.

(*Witness.*) You will see also that upon the 17th of October there is a tendency for a little more water to be going up the river.

(*Mr. Bidder.*) But it will be seen that the explanation of the one diagram here destroys the other. In diagram E you find that the upper float has made little progress up the river, whereas the lower float has made very great progress. Explanation suggested that that is the effect of the land-water, which is more marked in the upper reaches of the river than in the lower, where the sectional area is larger; but in diagram B the upper float makes a progress up the river, while the lower float is swept out to sea. If the restricted section of the river had anything to do with it, that would be fatal to the first explanation.

(*Sir John Coode.*) Upon the 29th and 30th of September there is only half the water coming over Teddington Weir.

(*Mr. Bidder.*) It ought to have the same relative effect.

(*Chairman.*) When you say the sewage goes down at the rate of half a mile a day, that cannot be all the length of the river; you must mean at the outfall

(*Mr. Bidder.*) When I said half a mile a day, I believe that applies to the district in the neighbourhood of Crossness. Of course, as you go further down there would be a diminution corresponding. We are speaking there of the downward motion as produced by the pushing down influence of the land-water.

8200. (*To the witness.*) Am I right in treating that half a mile a day as due to the theoretical displacement of the sewage by the pushing down of the land water?—It all depends upon the amount of the land water coming down. I have not worked it out.

8201. We will work it out now. You gave us the other day the amount of land-water, you told us that the average amount of land-water over Teddington Weir and the tributaries above the outfall was 120,000 cubic feet a minute. I think I am right in that?—I think I gave the mean flow as being 30 cubic feet from a square mile, which I believe is very nearly the quantity that came down upon the 22nd of September.

8202. Taking that 30 cubic feet that corresponds with my 120,000 cubic feet. Now your own table shows that at Crossness the sectional area is at high water about 75,000 square feet, and at low water 30,000 odd?—At high water at Crossness 75,000 and at low water 30,000.

8203. That 120,000 feet a minute passing that sectional area would give you a downward motion of a little over 18 inches a minute at high water at 1·6 or 1·7 of a foot, dividing the sectional area into 120,000?—I am taking the mean between high and low water. Taking it at 120,000, it is 2·28 feet a minute.

8204. That would be equal to three quarters of a mile a day at that spot?—It gives 3,283 feet.

8205. Consequently I am right in this: that taking the mean effect the whole year round if there were no mixing action, and if the water at Teddington weir were pushed into the river like so many successive charges from the tube of a gun, it ought to pass Crossness at the rate of three quarters of a mile a day?—Yes; that was upon the old theory of displacement, but we have pointed out that by reason of the mixing action it goes very much quicker, because instead of that same volume of up-land water displacing the whole of the water in the channel, it has only to displace that part of the body of water in the channel which is occupied by the fresh water and the sewage itself.

8206. That you say would be varied in other parts of the river by the increase or decrease of the section?—The displacement theory would assume that there is the same proportionate amount of fresh water in the river all the way down, and that the motion would gradually become slower and slower as the section increased.

8207. Your mixing theory would be another influence superimposed upon that, helping to distribute the sewage and to accelerate its progress lower down?—Yes, that is so; but the mixing action is so great that it overrides altogether the influence of displacement as put by you.

8208. But its action is in the same direction, to carry it down seaward?—Yes.

8209. Now to come back once more to the general result of your floats. Inasmuch as the land water, would as you say, drive down past Crossness at the average rate of three quarters of a mile per day, the result of your float experiment is, on the whole, to show not a tenth part of that; is it?—I say the floats have nothing whatever to do with this question of displacement. One simply shows the oscillation of the tides and the other shows what is the natural displacement in the river by the quantity of fresh water coming down.

8210. Then will you now admit that what happened with the floats is no guide as to what happened with the sewage?—No; I say these floats show that whatever happens with the floats may happen with the sewage; wherever they go sewage may go.

8211. (*Chairman.*) I think you say that if there were displacement only it would be at the rate of three-quarters of a mile a day?—Three-fifths of a mile a day.

8212. If that were so, if the float had been kept in the displaced sewage, it would have gone down at the rate of three-quarters of a mile a day?—Yes, if the float could have obeyed the natural flow of the stream, which it cannot, as the velocity in every part of the stream varies. One float cannot give the mean velocity of the stream; therefore you get these apparently discordant results.

8213. If the float had been a part of the sewage, as we may assume, it would have gone down the stream at the rate of three-quarters of a mile a day?—Yes, the total volume would; but I am pointing out that a particle of sewage would obey the same action as the float.

8214. The action of the floats, therefore, conveys an erroneous impression?—They give the range of the tides, and not the progression out of the river.

8215. (*Mr. Bidder.*) Then, as showing what would happen to the sewage, you mean that if you had an atom of sewage twelve feet long and one foot out of the water (supposing such a thing to be possible), it might possibly follow the same rules as the float did; but as we do not generally get atoms of sewage of that dimension it does not give a very good idea of the motion of the sewage?—It gives the range, but it does not give the rate of progression.

8216. Does it give even that?—It does not give the actual mean of the oscillations.

8217. Does it give the actual fact in any particular tide, because how can the floats have gone wrong at all if these observations are right?—If you started two floats together in any tidal river, you would, in all probability, find that they acted very differently from each other.

(*Chairman.*) Supposing the float came out of the reservoir with the sewage, one would suppose that it would go as fast as the sewage; and leaving the mixing action alone one would suppose that it ought to go down the river at the rate of three-quarters of a mile a day. I do not say that the sewage may not find its way up the river, because a quantity of sewage may get a certain distance up, and then it may stop in an eddy, and it may be again carried up by the next up tide and taken still further; but it seems to me that what Mr. Bidder is contending for is demonstrated.

(*Witness.*) I say the floats only show the horizontal oscillation, and have nothing whatever to do with the ordinary displacement.

8218. (*Sir P. Benson Maxwell.*) Mr. Bidder made a statement to the effect that the sewage did go at a certain slow rate. Now either your tables go to contradict that statement, or they do not; if you admit that they do not, then surely the cross-examination may be very materially shortened; do they contradict it?—What we say is that the floats only show the oscillation, and have nothing whatever to do with the progress. We have already shown the progress. We admit Mr. Bidder's argument with regard to the displacement, and we have given evidence as to the mixing action, showing that the sewage does get out of the river under varied circumstances.

8219. Then these floats do not contradict Mr. Bidder?—They do not.

8220. (*Mr. Bidder.*) But nevertheless these floats are large bodies 12 feet high, and not obeying the flow of the water; whereas the sewage is in minute particles in suspension and obeying every motion of the water?—I admit that; but still there is evidence to show that wherever these floats have gone sea water has gone, and wherever sea water has gone sewage has gone; because the sea water could not have been carried up the river past the outfalls without carrying sewage with it.

8221. That is mixing together two things: the sea water and sewage got up by the mixing action, but you could not say that the float got up by the mixing action?—No, I do not say that.

8222. Now you do not at all dispute that as regards the great bulk of the sewage poured in at the outfalls, apart from the mixing action, the average mean effect is to drive it down below Crossness at the rate of three-quarters of a mile a day, the rate diminishing as the section grows bigger?—And that is affected also by the range, because that sewage is brought up by the tide a certain distance before it goes down again.

8223. Without discussing whether particular particles of the sewage may or may not find their way up to Westminster, for example, do you dispute that as regards the general mass of the sewage poured in at Crossness and Barking the mean progress seaward would be three-quarters of a mile a day at Crossness, and slower as the sectional area grows larger, apart from any mixing action?—That is the law which governs displacement.

8224. Then let me draw your attention to this: you talked about your chlorine diagrams. There seem to be some difficulties, as far as we understand them, in following out some inconsistencies in them; you referred us to page 6 of the blue paper diagrams, and you there give us tests showing the quantity of chlorine, and the quantity of up-river water mixed with each volume of tidal water on several days. I quote this because you refer to this as corroborating some other views of yours. I see you show there the quantity of upper river water mixed with each volume of tidal water at St. Paul's Pier as being 8·2; does that mean that there was eight times as much river water as sea water?—That is the ratio between them.

8225. I will take first low water, when there was 803 times as much river water as sea water?—Yes.

8226. Now, will you refer to another table that you put in upon the very same day; at the very same low water you show 983 times as much river water as sea water?—The explanation is very easy.

8227. I want to get the fact?—The fact is that in the blue table the tidal water, which it is compared with, is Southend water, whereas the ratio in the white table is the ratio compared with sea water. I made those tables to show how little difference there was in the mixing.

8228. Is it not that the one contains the sewage and the other does not?—No, not wholly. The blue table is headed "Table produced from chlorine tests "showing the quantity of upper river (Teddington)

*Mr. B. Latham, M. Inst. C.E.*
31 Jan. 1883.

"water mixed with each volume of tidal (Southend) "water at various places in the Thames."

8229. The difference is as between 983 in the one table and 803 in the other; that is a difference in the ratio of 4 to 5. Therefore, if that is due to the standard being Southend water, the difference between Southend water and sea water is as four to five in chlorine?—But you must bear in mind also that this water in (*explaining the Table, see* Q. 7997) is upper river (Teddington) water, and has nothing whatever to do with sewage. Both explanations are necessary. It is quite true I have taken the two ends of the river to show what is the effect of the mixing; in one case Teddington water, and in the other case Southend water, without its having anything to do with the sewage.

8230. Does the difference between the two figures represent the sewage?—No.

8231. Is it because you have taken Teddington water in one case, and Southend water in the other?—I have taken both. I have taken river water and Southend water, both in the blue paper; in the white paper you have river water, sea water, and sewage.

8232. At low water the difference in the two tables, whether it is accounted for by the one containing sewage or not I do not know, is as between 803 and 983; that is a difference in the ratio of 4 to 5. Now, look at high water; one is 8·2, and the other 8·4; that is only the difference between 39 and 40?—That is what you would expect.

(*The witness explained the table to the Commissioners.*)

(*Sir John Coode.*) I have a suggestion to make which I think would bring out the facts which Mr. Latham has arrived at in a form much more useful to all of us; that is, if he could have plotted out a longitudinal section of the river surface at high-water and low-water. We should then see the gradients of the water surfaces under different conditions, and I think that would throw light upon this anomaly.

(*Mr. Bidder.*) If you are not satisfied already that these float experiments are worthless I shall be able to satisfy you by direct positive evidence that they are.

(*Witness.*) These sections have been made and will be brought before the Commissioners by Mr. Mansergh.

Adjourned to Tuesday next at half-past 12 o'clock.

---

# NINETEENTH DAY.

## Tuesday, 6th February 1883.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
FRANCOIS DE CHAUMONT Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S., Mem. Inst. C.E.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

Mr. BALDWIN LATHAM, Mem. Inst. C.E., further cross-examined.

6 Feb. 1883.

8233. (*Mr. Bidder.*) I will just ask you at once, as you have had a week to look into the matter, if you have any further observations to make with regard to these anomalies to which I drew your attention in your float experiments?—(*The witness handed in some diagrams, see Appendix A.D.*) These diagrams will explain the whole of the float observations during the period in which you say there are anomalies.

8234. Will you draw attention to anything in what you have handed in which throws any light, or which you think does so, upon these anomalies?—First of all, I will deal with Diagram A. of those which were put in by Mr. Bidder. I have here tracings which have the range of all the floats put on them, and which will, therefore, be more easily intelligible.

8235. Our diagram A. showed that No. 3 float went up a certain number of tides whilst No. 2 went down?—Yes; in Diagram A. the observations extend over five tides from the 18th to the 20th of September 1882, commencing with No. 3 Float at high water at Lambeth Bridge upon the 18th of September, and the comparison is between No. 2 and No. 3 Floats. Upon the diagrams which I have prepared, I have adhered to the same colour as you adopted in your diagrams. You will find that No. 2 Float, which is coloured yellow, starts at Greenwich and goes down the river, while No. 3 Float, which is coloured red, starts at Lambeth and goes up the river. At the commencement of the observations the floats are seven miles apart. At this time there were only three floats in the river, but it will be found, from comparing the diagrams, that No. 2 Float conforms with No. 1 Float, and No. 3 Float in the upper part of the river also shows a general conformity upon the 24th of September. No. 1 is coloured blue, No. 3 is coloured red, and No. 2 yellow, and you will find that the yellow and the blue conform generally (*pointing to the diagram*). Then upon the 24th of the month you will find that the other float implicated conforms.

8236. (*Chairman.*) Are these floats numbered as you had numbered them in your original paper?—Yes, they are numbered and coloured according to the plans put in by the Metropolitan Board of Works.

8237. (*Sir John Coode.*) You are speaking of the 18th and 20th of September, are you not?—Yes.

8238. But on this date this No. 1 Float does not appear?—No, but I have put it in as showing that it establishes the correctness of the movements of No. 2 Float.

8239. (*Mr. Bidder.*) But before you go any further will you allow me to ask you now, what do you suggest to the Commission as the reason why?—I will deal with them all, and then I will give my reason. I have one reason to give, which I suggest will apply to all these floats and explain their movements.

8240. But as I am cross-examining, I have the right to ask you, how do you suggest the fact is accounted for that the one float in a certain number of tides works up the river while the other float works down?—I will give you that when I have dealt with them all.

(The *Chairman* ruled that the witness was entitled to give a complete answer to the original question.)

(*Witness.*) No. 2 therefore conforms with No. 1 Float, but No. 3 differs; that No. 3 Float, however, is in the upper and shallower part of the river, and you will also find that upon the 21st of September No. 2 Float which is one of the floats implicated, went up.

8241. (*Mr. Bidder.*) But upon that other statement, that No. 2 Float conforms with No. 1, let me draw your attention to the diagram, from which it seems that it does not do anything of the kind; occasionally it does, but No. 2 is going up the river whilst No. 1 is going down. Your own diagram, for instance, shows that, if you take the 28th, the 29th, and the 30th of September, the No. 2 Float goes up the river and No. 1 goes down; how can you say that they conform?—I say that upon these particular dates which I have given to you they conform, and I have already called attention to the fact that No. 2 Float conforms to the action of No. 1 Float. At the beginning No. 1 Float goes down as well as No. 2.

8242. (*Chairman.*) No. 3 Float goes up?—No. 3 Float goes up, that being in a different part of the river; in fact, they are seven miles apart at the commencement.

8243. (*Mr. Bidder.*) But I venture to draw your attention to this,—that is, suggesting of course that there is something going on at one part of the river, common to No. 1 and No. 2, which is different from what is going on in the other parts of the river, where Floats Nos. 3 and 6 are?—That is the fact.

8244. Upon that I draw your attention to the fact that No. 1 and No. 2 conform at the time when they get closest together, that is to say, between the 28th and 29th of September. Now your diagrams show that from the 28th of September to the 30th of September No. 2 goes four miles up the river, whilst during the same period No. 1 goes down about two miles; if that is conformity, I do not know what is not; do you see that?—I do not see any irregularity at all in it, but I shall be glad if you will allow me to finish this one float first, because I am coming to the other dates, and I shall have remarks to make upon that point.

(*Chairman.*) If we are to understand the witness, we had better hear what he has to say upon the subject.

(*Witness.*) A very important point in the case is the direction of the wind. Upon the 18th of September the wind was N.N.W. and N. in the morning, and N.N.E. in the afternoon; upon the 19th the wind was N. and N.N.W., and in the afternoon it was N.W., N.N.W., and N.N.E.; upon the 20th, in the morning the wind was N.N.E; N.E., and in the afternoon it was E.N.E., E.S.E., and N.E.; the cardinal points are put upon my tracing, so you will see them. Now, by comparing the lower as well as the upper range of the floats, which are shown upon my diagram by dotted lines of the same colour, it will be seen that No. 3 Float is in conformity at both ends,—that is, the red float, which is in the higher part of the river. It will also be seen that No. 2 Float upon the 18th went up, so that there was some influence at work upon the 18th in the river which affected the floats. With regard to Diagram B., it only refers to three tides, the former one referring to five tides. Now, commencing with No. 5 Float from a point a little below Greenwich on the 22nd of September 1882, the comparison is between No. 5 Float and No. 4 Float. No. 4 Float, commencing off Woolwich, goes down, while No. 5 Float, commencing a little below Greenwich, goes up. The floats were over four miles apart at the commencement. During part of this time six floats were in the river. No. 4 Float generally conforms with No. 1, No. 2, and the lower range of No. 3 Floats; (that is important, because you will observe that the floats conform at the lower part when they do not conform at the upper part, that is to say, while the two floats are in the same part of the river, they conform to each other, but if they are in different parts of the river, there may be a disagreement); while No. 5 generally conforms with No. 3 and No. 6, which are in the higher parts of the river.

8245. (*Mr. Bidder.*) Upon what day is that?—That is from the 22nd to the 24th September; I am referring to your B. diagram. The direction of the wind upon the 22nd in the morning was N. and N.N.E., and in the afternoon it was also N. and N.N.E.; upon the 23rd in the morning it was a calm, and in the afternoon it was S.S.E. and S.S.W.; upon the 24th in the morning the wind was S. and S.W., and in the afternoon S.S.W. and S.E. No. 4 Float conforms with No. 3 and No. 1. The No. 5 Float was under an influence which was taking it to the upper part of the river, but it will be seen by comparing the lower range as well as the upper that there is nothing to throw doubt on the operations of this float.

8246. But I wish to call your attention to the fact that No. 3 Float was further up the river than No. 5 Float; when you say that No. 4 Float conforms with it, being in the same part of the river, No. 5 is between No. 4 and No. 3?—I am only speaking of their movement, which shows that there is a conformity between them.

8247. That is to say that some of them happen to be moving in the same direction; but, however, I will not ask you any questions just now.

8248. (*Chairman.*) Have you finished your statement?—As far as the B. diagram is concerned. Now, dealing with the C. diagram, these observations extend only to two tides on the 29th and 30th of September, commencing with No. 2 Float at high water, and the comparison is between No. 2 and No. 4 Floats. No. 2 Float off Greenwich goes up while No. 4 Float off Blackwall goes down. The floats are two miles apart at the commencement. No. 2 Float happened to get into the range of the influence of the higher part of the river, and conforms with No. 3, No. 5, and No. 6; No. 3 being red, No. 5 the neutral tint, and No. 6 burnt sienna. No. 4 Float conforms generally with No. 1 Float in the same part of the river, No. 1 Float being the blue and No. 4 the green. The wind upon the 29th in the morning was E.S.E., W.S.W., and N.W., and in the afternoon it was N.W. and S.W. Upon the 30th in the morning the wind was S.W., and in the afternoon S. and S.S.W. By comparing the lower as well as the upper range of the tides, both those tides will be seen to agree. There is a general conformity if you compare the lower ends, especially when they come into the lower part of the river. That concludes my observation as to Diagram C. Now, dealing with Diagram D., which gives observations upon 15 tides, commencing at high water from the 6th of October to the 14th of October with No. 7 Float, a little above the West India Dock, the following is the comparison between No. 2 Float and No. 7 Float. No. 2 Float at Angerstein's Wharf goes up, and No. 7 Float at the West India Dock also goes up; the floats are two miles apart at the commencement; No. 2 Float conforms with the lower range of No. 3, No. 5, and No. 6.

8249. (*Mr. Bidder.*) You must not say, conforms to No. 3 and No. 5, because No. 3 and No. 5 are one float. After a certain date they were not two floats, but the figures for No. 3 were taken as representing No. 5?—Exactly.

8250. If you choose to give it two names, that is your concern, but that must not be taken for the purpose of evidence, you know?—After the 5th of October there is a note upon the printed table which has been already put in, that "The figures of No. 5 "Float observations from the afternoon of the 5th of "October to the end of the experiment are the same "as of No. 3 Float."

8251. That shows a curious thing, that the two floats should come together, having been in different parts of the river?—Then No. 7 conforms with No. 3 (or No. 5) and No. 6 in the upper part of the river. Now the direction of the wind was as follows. Upon the 6th of October in the morning it was E.N.E., and

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883.

in the afternoon E.N.E. Upon the morning of the 7th it was E.N.E. and S.E., and in the afternoon S.E. and E. Upon the morning of the 8th it was N.E. and S.E., and in the afternoon it was S.S.E. Upon the morning of the 9th it was a calm, S. and S.S.W., and in the afternoon S.S.W. and S. Upon the 10th in the morning it was N.E. and E., and in the afternoon it was E., S., and S.S.W. Upon the morning of the 11th it was S.S.E., S.S.W., and S., and in the afternoon it was S.S.W. Upon the morning of the 12th it was W.S.W., W. and N., and in the afternoon N.N.W. and S.W. Upon the 13th in the morning it was S.S.W., W.S.W., and S.W., and in the afternoon S.W., N.N.E., and N.E. Upon the morning of the 14th it was N.E., and in the afternoon E.N.E. and N.E. Now between the 7th and 12th in this period No. 2 Float passed as rapidly upwards as No. 7, and No. 2 Float began to descend with No. 7 Float upon the 17th. Now we deal with Diagram E. In Diagram E. the observations are on two tides, commencing with Float No. 1 at high water on the 16th of October 1882; the observations go on upon the 16th and 17th of October, and the following is the comparison between No. 1 and No. 2 Floats: No. 1 Float is coloured blue, and is at the southern outfall and goes up, while No. 2 is coloured yellow, and starts at Greenwich and goes up; the floats are 8½ miles apart at the commencement; No. 1 Float conforms exactly with No. 4 Float at the same part of the river. No. 2 Float conforms with No. 7 Float. The wind upon the 16th in the morning was E.S.E., and in the afternoon E. and E.N.E. Upon the 17th the wind was N.E. and N.N.E. in the morning, and N.N.E. and N. in the afternoon. No. 1 Float conforms at both the upper and lower ranges; the lower range of No. 2 conforms with the lower range of No. 1; that is where they are both in the same part of the river. Now, taking these A., B., C., D., and E. diagrams, the number of tides which were implicated as being in error, and the number of floats implicated, are as follows:—A., number of tides, 5; B., number of tides, 3; C., number of tides, 2; D., number of tides, 15; E., number of tides, 2; making a total of 27; and the floats implicated are Nos. 1, 2, 3, 4, 5, and 7. The whole of them, except No. 6; but you will observe that upon No. 6 there is no implication, yet No. 3 and No. 5 follow it in parallel lines. Now these 27 tides are but 5·9 per cent. of all the tides in which the observations have been made, but if you deduct the eight tides in the D. diagram, in which it is shown that the two tides were flowing in parallel lines, then the implications only come to four per cent., assuming that they were correct. In all the objections one of the floats is always found in the most crooked part of the river, or between three and ten miles above the northern outfall; that is a very important point. You will find it is invariably in this very crooked part of the river that one of the floats implicated is always found (*pointing on the chart to the curves between Blackwall and Greenwich*), and the wind mostly acts across the river, tending to disturb the tidal current and to diminish the range by driving the float into shallow water or into eddies. The floats explain the action of the river from the very fact that in every one of these objections one of these floats is invariably in that part of the river, and what may appear discrepancies are really due to the influence of that part of the river in checking the progress of the float; butthe whole of the objections form such a very small part of the whole of the tidal observations that, assuming them to be valid, they can throw no doubt upon the accuracy of the general observations.

8252. That is a matter of opinion. Now is that the end of your answer?—That is the end of my answer to your question.

8253. Now, having come to the end of the answer, let us come back to Diagram A. All being said and done, will you tell me now whether it is a crooked part of the river or a straight part of the river; how you account for the fact that in a certain number of tides one float works up and the other works down?—Because, as I have told you, there is an influence which affects all the floats until they pass this crooked part which tends to get them down the river, whilst below this point, and when they have got past it, the tendency is for the floats to go up the river.

8254. Will you condescend to more commonplace language; the progress of these floats is determined by the flow of the water in the river?—Yes.

8255. You put them forward as showing what is happening in the water?—I put them forward as showing what is the oscillation of the tide simply.

8256. Do you believe in these periods referred to in Diagram A., that the water in the neighbourhood of Lambeth Bridge was, upon the whole, flowing up stream, while the water in the neighbourhood of Blackwall was flowing down stream?—I do not mean anything of the kind.

8257. Then you do not say that these floats represent the action of the tide?—I say they show tidal oscillation.

8258. They do not represent what the water did?—I say they represent the action of the particular particles of water just around the floats at the time, but not the general action of the whole of the water in the river.

8259. They do not represent what is taking place in the general body of the river, and therefore they do not represent what is taking place in the general flow of the sewage towards the sea?—I say they do, because wherever the floats have gone the sewage has gone, as is shown by the chlorine tests.

8260. You do not suggest more than this, that it is possible for a particle of sewage to follow the course of one of these floats?—I do not.

8261. Then I will leave that. Now, I take it that a good many of these anomalies are accounted for by the wind?—And tidal currents, which are affected by the wind, among other causes.

8262. By the wind acting upon the float?—Acting upon the tidal currents more than upon the float.

8263. What would be the effect upon a windy day if you made a float fast to the stern of a boat, and so took the float up stream?—It would not have much effect upon these floats; it would be a tremendous job to attempt to haul them up stream; they are so substantial and heavy that it would have little effect upon them.

8264. Just upon another point have you observed an anomaly of another character which I did not observe, so as to call your attention to it upon the last occasion, namely, that upon one particular day, the 29th of October, upon the afternoon ebb tide, the No. 1 and No. 3 Floats behaved in a very remarkable manner, because No. 1 started a couple of miles higher up the river, and ended four or five miles lower down, passing No. 3 at a good pace, and gettting a long way ahead of it; this relates to the same part of the river. No. 1 Float started at high water opposite Deptford Creek?—Opposite Greenwich Station.

8265. And at low water it ended below Greenhithe Pier?—At low water it ended at Messrs. White's cement works.

8266. Below Greenhithe Pier, is it not?

(*Sir John Coode.*) About 10½ miles.

8267. (*Mr. Bidder.*) Now, No. 3, looking at the very same tide, started, did it not, at Blackwall, a point about two miles lower down the river than No. 1, and ended opposite the River Darent, which is some miles above Greenhithe. I think it is called the Long Reach Tavern (*the spot having been pointed out*). Am I right in my facts?—It appears to be so.

8268. What was the point there; was No. 1 in better training?—No. 1, or the one which took the longest range, may have been more in the direct current.

8269. We have got rid of the suggestion that they are in different parts of the river or that different winds are blowing, or that they are in different bends of the river, because they are actually traversing the same part of the river; and the one has made a six

miles better journey of it than the other in the same tide; does that increase your confidence in the reliability of these experiments?—I do not see anything to throw doubt upon them.

8270. (*Mr. Abernethy.*) Were not your floats liable to take the ground occasionally?—Certain instructions were issued with the floats, viz., that the men were not to interfere with them at all unless they got aground; consequently, instead of being driven, as they usually are, right down the tidal way, they were left alone, so that one float might have got into the slack water at the side.

8271. (*Sir John Coode.*) As a matter of fact, they were not frequently interrupted by the men?—I have seen them, when I have been down the river, pulling them out when they were liable to go aground at the side of the river.

8272. Would that state of things be recorded by those who took the observations?—I daresay it would, but when I have been on the river I have seen one float, which was in the tideway, pass one which was in the slack.

8273. (*Mr. Bidder.*) Have you ever seen the float aground, and the two men in the boat comfortably asleep, and anchored to it?—I do not think two men in charge of a boat would be likely to go to sleep.

8274. (*Mr. Abernethy.*) In placing the floats in the river, did you place them in precisely the same point of the river as regards the channel?—When they started; but you will observe that those observations were taken at a very disturbed period of the year, when they were constantly liable to be interrupted by storms, when the water was very rough, and there would be very great likelihood of some of the floats getting into the slack water.

8275. (*Mr. Bidder.*) Before I leave the floats, I wish to ask you another question which arises upon your report. At pages 30 and 31 of your printed report you give certain observations of what you call experimental floats. I thought they were all experimental. But, however, you call these "experimental floats." Now these floats are not tabulated in your final tabulations; am I right in saying this, that the rate of progress of these floats was immensely greater than that of the others?—Certainly, for the simple reason that those floats were ordered to be kept in the full tidal way, whereas the others were ordered not to be touched unless they were likely to get aground.

8276. Those were kept in the full tidal way, both ebb and flood?—Yes.

8277. And, being kept in the full tidal way, they showed a very rapid progress indeed seaward?—Yes.

8278. No. 8 Float, you say, went down upon the first ebb 15½ miles, and only came back 6¾ miles. Upon the next ebb it went down 15 miles, and on the following flood it only came back 11 miles?—Yes.

8279. (*Mr. Abernethy.*) What is the character of these experimental floats as compared with the others?—They were to ascertain the different velocities in different parts of the river.

8280. Were they both the same shaped floats?—They were both long floats, of the same pattern as the others.

8281. (*Mr. Bidder.*) But, although they were designed to show something else, it may be said that they throw light upon this subject too?—And also there is this to be said, that at the time these floats were in the river flood water was in the river, and that would give a greater rate seaward than was the case with the other floats.

8282. I thought you would say that, so I wished to show that your diagram floats upon the same days were not going down the river at anything like the same rate of speed?—They ought not, according to the instructions. The instructions were that the diagram floats were not to be interfered with, but the instructions in the case of the No. 8 Float, now before you, were that the floats were to be kept in the full force of the tidal way.

8283. As regards the tabulated floats, the instructions practically come to this, that if the float got out of the tideway, and were blown, for example, upon one side, and got into an eddy, it was not to be interfered with so long as it did not actually stick on the ground?—That so long as the float was moving down the river, however slowly, it was not to be interfered with, but the length of the float itself was sufficient in my opinion, to prevent its getting into the slacks; for wherever there was sufficient water to swim the float, it would indicate that it was in the fair flow of the river.

8284. But there are points of 12 feet deep in the river where there is a slack?—Yes, but if the man saw his float going aground, he would pull it out.

8285. (*Sir John Coode.*) I think the instructions to the men had better be put in, as we have heard a great deal about them?—The instructions were as follows:—

"The float observations in the Thames are to commence on the 14th September, on the afternoon tide, the first float being placed in the centre of the stream, opposite Barking outfall, on high water at this point, just as the tide is commencing to turn, the exact time the float starts to move down the river being recorded. A peg should be driven into the shore level with the water, and the level of the water should be ascertained at the time the float was inserted. Three hours after the first float has been started, a second float should be started at the same point, and the level of the water should again be ascertained in the same way with reference to the second float. At low water on the same tide a third float should be started, the level of the water and the time being carefully noted. The above-mentioned floats, numbered 1, 2, 3, are to be watched by the persons in the small boats, one boat's crew to have charge of one float and never to lose sight of it, with instructions that if the float gets fouled against any bank or vessel the boatman is to immediately draw the float out into the tidal way, but by no means to accelerate or impede its progress up or down the river. A record must be kept of the times and places at which the floats foul any object. Any doubtful observations should be noted and reported, especially if the floats are observed to make little or no progress in any portion of their course. On the high water of the 14th September the chemists are instructed to draw samples of water, as well as upon the previous low water, so that the float observations must commence on this particular tide. On the 22nd September, being neap tide, upon the high water in the afternoon tide of that day, the second series of float observations will commence off Barking, the floats being numbered 4, 5, and 6, and these will be placed in the charge of men in small boats with instructions similar to those before given. Each boat must carry small supplementary floats, and in case of the detention of the larger float the smaller float must be put into the river at once. Spare floats of the larger type must be stored at known points, so that in case of accident the larger floats can at once be replaced; but in all cases, awaiting the procuring of the larger floats, the small supplementary floats are to be used to keep up the continuity of the observations. It will be necessary when the men change from day to night work that there should be some system of recording the position of the boats, so that when an exchange takes place the fresh men may know at what point to meet their boat. Under no circumstances are one set of men to leave a boat until the relief men have entered upon their work, and on no account are the men, especially at night, to lose sight of the floats in their charge. While these experiments are going on, and the steam tug is not required, observations upon single tides should be going on in the mouth of the Thames, first with a view to ascertain at every state of the tide how far the tide flows up the river, for which purpose every day for the first fortnight a float or a couple of floats may be put in the water at extreme low water off Southend Pier; and secondly, it is desirable to know the point in the Thames where, if the sewage is

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883.

discharged every 1, 2, 3, 4, or 5 hours after high water, sewage would pass out to sea. This may be ascertained by putting in floats in different positions in the lower part of the Thames so as to get these results. The experiments with the floats at low water will give approximately a point near which anything admitted at high water would all pass outwards. It is also desirable that experiments should be made to ascertain whether, if the floats are carried out to sea from the Thames, they are likely to be brought back by the succeeding tide into the river again. For this purpose spare floats numbered 7 to 12, when not required for other experiments, may be used. These latter observations need only be carried on on single tides, and the information may be got in the day tides. The observations must, however, be carried on when the tides are making as well as when they are falling. The direction of the movement of the floats outside the river should be shown on a chart."

8286. (*Mr. Bidder.*) Now these instructions do not quite carry out what you say they did, because you say the men are never to lose sight of the float, and are only to interfere with it if it gets fouled against any bank or vessel, then they are to draw it into the tideway; but if it gets into an eddy, there are no instructions?—But there is an instruction that it is to be noted if it makes very little progress in its course.

8287. Have you recorded any instance of that?—I have no doubt it is recorded.

8288. Again, if a float fouls a vessel, it is to be drawn into the middle of the tideway?—Yes, if a float fouls a vessel, it is to be drawn into the tideway, certainly.

8289. So that another contingency comes in, it depends upon how many times the float has come into collision with a vessel, how many times it has been drawn out into the middle of the river?—We have had one float smashed by coming in contact with a vessel.

8290. So that, as regards No. 1 Float, I draw your attention to the fact that No. 1 Float had been very fortunate in coming into collision a great many times and being put frequently into the middle of the river?—That would not have been the reason of its progress; it was in a very stormy season, when there would not have been many vessels going up and down.

8291. I will now leave that part of the case and pass to the chlorine tables, and ask you certain questions about them, and about certain tables which you handed in, showing the effect of the mixing action. I have before me that table in which you gave the area of the cross section of the river at different points, and the ratio of river water and sewage combined to sea water. I think that has been handed in to the Commission?—There are two tables of the kind.

8292. I want to see how much of this is fact, and how much is inference; as regards the area of the cross section, that I believe is matter of calculation from the plotted section in the ordinary way?—Yes, that is the area taken out by Mr. Mansergh.

8293. Now, as regards the rest, namely, the question of what are the relative proportions of water and sewage and sea water, and consequently the sectional area occupied by each, and the time of flowing down the river, those are matters of inference, are they not?—Those are calculated in the way which I have already explained very clearly upon the notes.

8294. The observation upon which the calculation has been based being that at each of those places you took a sample of the water of the river and then ascertained that there were so many grains of chlorine in it?—You are not right in saying "a sample"; in every one of those cases a large number of samples were taken across the surface and at 20 feet in depth, and this is the average of all the samples at every point; it is not one sample, it is the mean result.

8295. From these samples you have obtained so many grains of chlorine in a sample?—Yes.

8296. Then you reason, assuming that sea water contains 1,961 parts, and sewage 10, and the water of the River Thames 1·7, as to in what proportion the two are compounded at that place?—Yes, exactly, those being the figures absolutely known to be the amount of chlorine in those descriptions of liquid.

8297. To begin with, you have to make an assumption as to what is the proportion of sewage to river water, have you not?—Certainly, and I have already told you that the sewage has been taken at the standard estimate of five cubic feet per head of the population.

8298. You assume in each case that there was such a proportion of sewage; so many million gallons of sewage and so many million gallons of river water coming over Teddington weir upon that day?—Such a quantity of water coming into the river at different points, not only at Teddington.

8299. Take, for instance, that 14th of September, and for illustration I will take the result at Crossness, where you say there is a ratio of 1·14 river and sewage water compared with the amount of sea water?—Yes, at high water.

8300. Is not the ratio between the river and the sewage water derived from assuming that there was the amount of sewage you have stated from the population, and that amount of river water which your tables show coming over Teddington Weir, and from the other tributaries upon that day?—Yes, I said so.

8301. Is not that necessarily erroneous for this reason, that the river water which came over Teddington Weir upon the 14th is not the quantity that is mixed down at, say Crossness, upon that day, and would not be mixed down at Crossness for several days to come?—But I do not admit it to be an error, for according to the theory of impulse, whatever is put in at the upper end would push out an equal volume at the lower end of the river.

8302. Do you mean to say that, if we suddenly alter the volume of the water that went over Teddington Weir, that would produce an instantaneous alteration at Crossness?—Yes, or very shortly in proportion to the speed at which the impulse can travel. If you put a quart of water into the upper end of a long channel or a short channel, a quart will speedily run out at the lower end.

8303. So you consider that you are justified, however many miles there are from Teddington Weir to Crossness, in adopting the quantity of water coming in at Teddington Weir as representing an equal quantity of river water all the way down the river?—Yes, I am justified in that.

8304. You say that sewage water contains 10 parts of chlorine to 100,000?—Yes.

8305. Are you aware that it contains over 20?—No, I am not.

8306. Where did you get the 10 parts in 100,000 from?—Our chemist gave us the figure; it is the generally accepted estimate.

8307. At any rate you would admit that if it contains 20 instead of 10 parts the whole table would be vitiated?—Not at all; it would have to be modified to that extent; but the difference between whether it is 10 or 20 when mixed with river water, and 1,961 is very slight.

8308. You mean to tell the Commission that, in estimating the amount of river water and sewage in any part of the river by the chlorine, it matters very little whether you take 10 or 20 parts to 100,000 of chlorine in sewage?—Certainly.

8309. Do you tell the Commission that it is of very little moment in making these calculations whether there are 10 or 20 parts of chlorine to 100,000 in the sewage?—I have a table here which shows the result, supposing that there was no sewage in it at all.

8310. I would rather not go into another table unless it is absolutely necessary?—I say that when you get to the lower parts of the river it will make very little difference indeed.

8311. (*Chairman.*) The ratio would be 10 to 1,961 in one case and 20 to 1,961 in the other?—Yes, but the volume of the sewage is very much smaller than of the tidal water.

8312. (*Mr. Bidder.*) So that in each of those calculations you made two assumptions. Having said, for instance, that there were four grains of chlorine in a particular sample, you said, "I first assume that "what fresh water there is is, in a certain proportion, "river water and sewage, and then I next assume "that the sewage has 10 grains of chlorine in "100,000 parts"?—Yes. Will you allow me to inform you that according to the calculations as they now stand the initial quantity in the river is 1·7, and that at Barking, with the sewage added, that 1·7 comes to 2·42; that is, with the 10 grains of chlorine in 100,000 parts.

8313. You have not worked the calculation out by the 20?—No, but you will see that, if taking it at 10 parts only increases it by 0·72, the other would only further increase it by 0·87, which would bring it to 3·29, so that the amount of chlorine, instead of 2·42, would be 3·29 in 100,000 parts.

8314. That is pretty well to begin with?—But that will come to a very slight difference when you come to the open part of the river.

8315. I began the other day to compare another table you put in with the series on the blue paper at page 6. I was drawing your attention the other day to this, that, looking at the two tables (I will take the same illustration I took the other day) at St. Paul's Pier upon the 14th September at low water, your first table represents the ratio of water and sewage combined to sea water as 983 to 1?—Yes.

8316. The table No. 6 on page 6 of the blue paper upon the same day, at the same low water, and at the same place, St. Paul's Pier, represents the ratio of upper river water to Southend water as 803?—Yes.

8317. And I think the other day you accounted for the difference by saying that in one case the comparison was to sea water, and in the other case it was to Southend water?—Yes.

8318. So that, to begin with, you can vary the figure from 803 to 983 by saying that it was Southend water instead of sea water?—And in the first case it was river water with no sewage in it. Reading the head of the table, it will be as clear as possible.

8319. I wanted you to fall into that trap, and you would not the other day. Then let me draw your attention to a very curious thing. Am I to assume that the difference between the 803 and the 983 represents the sewage?—No, do not assume anything of the kind.

8320. Then how do you account for this, that, whereas at low water there is that enormous difference, if you look at the same place at high water, the ratios vary very little?—Exactly; because in the one case the river water is taken at low water, and in the other case at high water when it is nearly all tidal water.

8321. But comparing the two tables at low water, there is an enormous discrepancy between the results of the two tables, one being 983 and the other 803; but at high water the discrepancy is almost imperceptible?—I want to explain that, if you take the figures and work them out by the formula I gave you, you will find that both figures are absolutely correct. I have worked them out, and they show the correctness of the result.

*The following paper was handed in:—*

On Sept. 14th the amount of chlorine in the sample at high water was 210·7.

On Sept. 14th the amount of chlorine in the sample at low water was 4·1.

In one case "a" the amount of chlorine in tidal water = 1931.
and "b" " " river " = 1·7.

In the other case "a" the amount of chlorine in sea water = 1961.
and "b" the amount of chlorine in river water and sewage combined = 2·11.

$\frac{a-c}{c-b}$ in one case $= \frac{1931-210{\cdot}7}{210{\cdot}7-1{\cdot}7} = \frac{1720{\cdot}3}{209} = 8{\cdot}2$ { the ratio of river water to tidal water.

$\frac{a-c}{c-b}$ " $= \frac{1931-4{\cdot}1}{4{\cdot}1-1{\cdot}7} = \frac{1926{\cdot}9}{2{\cdot}4} = 803{\cdot}$ do

$\frac{a-c}{c-b}$ in the other case $= \frac{1961-210{\cdot}7}{210{\cdot}7-2{\cdot}11} = \frac{1750{\cdot}3}{208{\cdot}59} = 8{\cdot}4$ { the ratio of river water and sewage combined to sea water.

$\frac{a-c}{c-b}$ " $= \frac{1961-4{\cdot}1}{4{\cdot}1-2{\cdot}11} = \frac{1956{\cdot}9}{1{\cdot}99} = 983{\cdot}$ do.

8322. If the discrepancy were due to taking the Southend water instead of the sea water, it would affect both parts of the table equally?—But you observe that in one case you have not only got Southend water at one end of the river, but you have upland water at the upper end of the river. The object of the table was to show what would be the effect of mixing these two waters, totally independent of sewage or anything else, which would be going down the river, and then it shows you that when you come to high water there is very little difference indeed in the mixing action in the river. In one case the proportion comes to 8·2, and in the other case to 8·4, but they are both absolutely correct.

8323. But you do not quite understand the point of my question. At high water at St. Paul's Pier the two tables are very nearly identical in the ratios which are given, viz., 8·4 and 8·2?—Certainly.

8324. At low water the discrepancy between the two tables has become very great, and, inasmuch as in both cases the difference of Southend and sea water affects the two tables in the same ratio, it must be due to the sewage that the discrepancy is increased?—That is one of the causes, there is no doubt.

8325. Then it seems to show there is more sewage at low water at St. Paul's Pier than there is at high water?—No, it does not show anything of the kind.

8326. Now I will ask you another question. Seeing that it is Southend water that comes up the river, and not pure sea water, would not the Southend water have been the more reliable and proper standard to have taken in this other table rather than sea water?—No, it would not, but as a matter of fact, you will see how small a difference there is; you will see that the tidal water there, for the purpose of calculation, is taken as containing 1,931 parts of chlorine at Southend upon the 14th instead of 1,961.

8327. Where is that?—That is in the chlorine table itself; the quantity given by the chemist is 1,931 in 100,000 parts at Southend as against 1961 parts in sea water.

8328. Then, in point of fact, the difference between sea water and Southend water has nothing to do with it?—I have already told you that it has.

8329. The difference is very minute?—It only shows that by taking that quantity at any particular time the tidal water at Southend differed very little from real sea water.

8330. Then if that be so, it must be the presence of the sewage which accounts for the difference?—I have already told you that the sewage accounts for a quantity of the chlorine in the water.

8331. At page 4 of your tables you give another analysis with regard to chlorine. I will now ask you a question to see how far this method of yours is trustworthy. The table is headed "Chlorine in 100,000 parts of Water," at different places. One very startling result to which I draw your attention there is that upon the 30th of November the sea at Margate had 1,770 and 1,735 parts of chlorine, and I think it would follow that, according to your calculation, the sea at Margate was 10 per cent. sewage and river water. The application of your process of inference, if it is a trustworthy process, leads to that conclusion, does it not?—It does not follow at all.

8332. If your sea water is 1,961, applying that same process to the other table, does not it come to that?—No, it shows that the sea water even there was very diluted from some cause or other; but whether it was sea water, or whether it was anything else, it does not show; it might have been pure river water which was mixed with the sea water.

8333. So that your standard of 1,961 might have been incorrect?—No, it is admitted by the generality of chemists that that is the standard of sea water.

8334. Only that, as the Thames is fed at flood tide from the sea at its outlet, it shows that the Thames at its outlet may differ from the standard?—That shows that the sea was very diluted at that point on that day.

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883.

8335. That shows that the sea water when it gets into the Thames may differ very far from your standard?—It only goes to show that the Thames influences this water at Margate to a very great extent, and that the tidal water coming in is very largely the water that has gone out of the Thames previously.

8336. Now I go to another point upon which I wish to ask you a few questions; you told the Commission that Sir Joseph Bazalgette's scheme of main drainage as carried out was designed for, and equal to, a population of 500,000 less than that which now exists?—That is according to the figures in your own report.

8337. The population, correctly given from the Registrar-General's Returns, is shown in your table as 3,800,000 and odd, but are you aware that of that population a certain proportion not only does not drain into the Metropolitan drains, but drains in other directions, and always will?—What portion may I ask are you referring to, which always drains in an opposite direction?

8338. Are you aware that a part of the population within the Registrar-General's area of the Metropolitan District does drain in other directions, and does not drain into the Metropolitan sewers at all?—I am aware that within the Metropolis there are a very large number of drains into the Thames, the sewage of which does not go into your sewers.

8339. Are you aware that a part goes into the West Kent drainage?—I am aware that you have power to put it in, but that is a very sparsely populated district, and that is beyond the area of 40 square miles on the south, which is included within your limits.

8340. I am doing my duty if I ask you whether you are aware that we have such a power?—I am aware that you have such power, but I am not aware that a drop of your sewage goes into that West Kent system; the district is very sparsely populated and is nothing as compared to the general population.

8341. When you speak of what Sir Joseph Bazalgette designed his works to carry off, as compared to what they are doing, is it not the fact that in designing these sewers for three and a half million people it was estimated that they would have to deal with a maximum flow, which was double the average flow?—I have already told you.

8342. I wish you would not say that you have already told us everything?—I have said that you calculated the sewage at five cubic feet per head, half of which was to flow off in six hours, and that, as shown by the southern gaugings at Crossness, instead of half the sewage flowing off in six hours, it flows off on that side in nine hours.

8343. Now will you answer the question: were the sewers designed upon the assumption that the maximum flow would be double the average flow?—They were designed upon that assumption in certain districts; in each separate district.

8344. Was the whole system designed upon that assumption?—I have already said that the northern outfall sewer was half made before the western sewage was taken there, and therefore, to the extent of the western sewage, the northern outfall is not large enough.

8345. Were not those sewers designed upon the assumption that the maximum flow they would have to deal with would be twice the average flow?—Down to Abbey Mills they were designed upon that assumption.

8346. I am not talking about whether the western district was taken in or not. I am asking you whether the maximum to be dealt with was not in the ratio of two to one of the average?—It is impossible to answer the question unless you take into account the western district sewage.

8347. (*Chairman.*) Do you know upon what assumption they were designed?—I have already stated that the assumption was five cubic feet per head per day, half to flow off in six hours.

(*Mr. Bidder.*) Does experience show that the maximum flow is only 40 per cent. greater than the average flow?

(*Mr. Lumley Smith.*) You mean the maximum flow through the sewers.

(*Mr. Bidder.*) Yes.

(*Witness.*) I cannot say whether that was so or not, for this reason, that we have only got the gaugings upon the south side, and I have shown you that the gaugings upon the south are 50 gallons a head, instead of 30 gallons a head, and we have nothing to guide us upon the north, except the figures given us by Sir Joseph Bazalgette, which I have already analysed, and have shown what an immense difference there is between the figures for the north and the figures for the south.

8348. (*Mr. Bidder.*) Do you know that the maximum flow is only 40 per cent. greater than the average flow?—Upon the south.

8349. And upon the north?—How can I know what it is upon the north?

8350. By examining the figures, which have been supplied?—There have been no figures supplied for the north, and I have given you the figures for the south.

8351. If that be the fact, the sewers which were sufficient to carry off the sewage of three and a half millions, upon the assumption that the maximum flow was double the average, would be equal to carry off the sewage of a very much larger population upon the assumption that the maximum is only 40 per cent. greater than the average; would not that be so?—Yes; but you must bear in mind that by reason of the very large amount of leakage into the sewers upon the south the flow is rendered more uniform on that side.

8352. You found, you say, an enormous leakage into the sewers upon the south?—Yes.

8353. How did you deduce that leakage?—I took it from the figures which you put in in the Mud Inquiry, showing that in the driest period we have ever known, namely in July 1876, although the water supply was 30 gallons a head, yet, during the same period the flow from the sewers was 50 gallons a head, showing that the leakage was equal to 20 gallons a head per day.

8354. Would you be surprised to hear that it was the practice of the Metropolitan Board of Works to let water from the Thames into the sewers in order to flush them?—I think it would be very curious if they were doing so at the time when they were making gaugings to ascertain what the flow of the sewage was.

8355. Are you aware that that is the practice?—It would seem very curious to me if as you say they were doing it then.

8356. If that is so, then that would destroy your inference?—If, at this period, they were letting in 20 gallons per head from the Thames, then that would modify the inferences very much, but I should be very much surprised if at the time when they were making those observations they were doing so.

8357. Now I pass to the tables, showing the population and death rates of certain places; viz., Barking, Grays, Dartford, and Gravesend; can you give the Commission any idea of what is the area and the position of the districts which in the Registrar-General's Tables go by those names?—They can be got; there is a plan published showing them.

8358. Are you aware that some of the districts go far inland and include populations remote from the places from which they take their names?—Yes.

8359. You are aware that those include populations which are not riverside populations?—I stated that those were registration districts; there are plans published in the Census returns which show the whole of them.

8360. Dartford is really close by the river, but the Registrar-General's Dartford goes far inland?—Dartford itself is upon the Darent, but Erith in the Registrar-General's district is included in Dartford.

8361. The district goes inland three or four miles? Yes; the district goes inland to a considerable extent.

8362. Is that idea of adopting the ratio of the births divided by the deaths an original one of your own, or has it the sanction of any sanitary authority? I have not seen it, except in my own hands.

8363. Have you ever heard it adopted or suggested by anybody before this inquiry?—No; but I have used it myself for years.

8364. Was it invented for the purpose of this inquiry?—No; nothing of the kind.

8365. Not discovered for the purpose of this inquiry?—Nothing of the kind; I say I have used it for years.

8366. It never occurred to anyone else?—Perhaps it has never occurred to anyone else.

8367. Now, with regard to the temperature, what is your warrant for saying that the Thames becomes offensive in a temperature of about 65°?—I put it between 65° and 70° from the evidence of the most eminent chemists, who have stated that at that temperature putrefaction and fermentation are most active.

8368. Where is the evidence of the eminent chemists who state that at that point putrefaction or fermentation begins?—You will find that there was a good deal of evidence upon that point given before the Select Committee of the House of Commons in 1858.

8369. Would putrefaction or fermentation begin with a temperature of 65°?—No; I do not say that, but I say, assisted by a high temperature of the mud.

8370. You stated specifically 65°?—I stated from my own information that the river becomes offensive with rapid fermentation at from 65° to 70°. It was the evidence which was brought before that Committee of 1858 with regard to the state of the River Thames which drew my attention to it, in which it was shown that the temperature of the water was then 70°, and the temperature of the mud was 120°.

8371. I do not think that that shows it?—Simply by analogy, that the river was more offensive that year, when it had been very warm for some months and for a longer period than it had been in previous years, and it was a very dry year as well. There is one reason I ought to mention, why the Thames becomes so offensive in summer time, viz., that in the summer time there is a very large amount of mixture of salt water with the Thames water and the sewage, and whenever sewage and salt water mix together they produce the most offensive compounds, and of course the drier the period the more salt water there is in the river. In fact so potent is this influence that in Messrs. Bazalgette, Bidder, and Hawksley's Report of 6th April 1858, at page 32, they actually point out that if the Government Referees discharged the sewage of London at Mucking Lighthouse which they proposed, it would seriously incommode Gravesend, which is seven miles distant. Now, in summer time, the sewage is discharged at Barking and Crossness into the river, which is then quite salt, and consequently must create the most offensive effluvia at that particular period.

8372. You have made a very extensive excursion, how does this show that 65° temperature produces this offensive smell?—Because at that time, in dry weather, there is a very much greater tendency for the salt water to come up the river.

8373. (*Chairman.*) You mentioned 65°, is that the result of your own observation, or is it taken from some authority of chemists?—I have always said that it was after 65° and up to 70°.

8374. Is that the result of your own experience, or did you take that as a fact from somebody else?—It is the result of my own experience, but with regard to the Thames, I specially referred to the temperature which was brought out in 1858 before the Committee referred to.

8375. (*Mr. Bidder.*) As I understand you, in summer time in dry weather, there is a larger proportion of sea water in the river?—In July, to which the Report referred, there is, owing to the dry weather, a larger amount of sea water.

8376. Is not July the second wettest month in the year?—There is a large amount of rain water which falls, but it does not run off except from the roofs, and the roads, and the sewers.

8377. Now you gave certain figures with regard to the weight of solid matter in suspension in the sewage, which you said you took at 3½ oz. per head of the population?—Yes, for everything.

8378. And that works out to how many tons in the year?—132,000.

8379. Are you aware that that is wet and not dry?—I have already explained clearly to you that that included all the solids both in urine and in fæces, and, in addition, any solid matter which went into the sewers.

8380. Do not you know that the solids in urine are solids in solution and not in suspension?—I told you that that particular 3½ oz. I laid no stress upon; it was only in corroboration of the general calculation.

8381. Now I will draw your attention to the evidence of Dr. Frankland upon this point, and ask you whether you agree with it; at page 462 of the evidence given on the Mud Inquiry, oddly enough, Dr. Frankland gave almost the very same figures as you,—130,000 tons per annum; and I see he was cross-examined by myself upon that point. I will not read it all in detail, but you will see at Question 4531 in answer to Mr. Bramwell, who said, "52,000 "tons I make it," he says, "Yes, of course, 52,000 "tons dry, if the present statement is correct, becomes "130,000 tons wet, that is the difference.

"(*Mr. Bidder.*) There would be 60 per cent. of "water in that.

"(*Mr. Bramwell.*) It comes to 52,000 dry, does it "not?" 52,000 is a misprint,—it should be 32,000. Then at Question 4533, I say, "There are a lot of "gentlemen behind me who suggest that you under-"state the quantity of water in fæces when you speak "of 60 per cent.; it is more like 75 per cent.?—"(*A.*) I do not think that there will be more dis-"crepancy about the percentage of water in wet fæces "than the percentage of water in those mud banks. "(*Q.*) But, however, we are turning fæces into dry "matter?—(*A.*) Oh, very well. (*Q.*) Then I must "take a fourth?—(*A.*) You may take a fourth." Now if you divide the 130,000 by four, that is exactly 32,000 and a small fraction. Then says Mr. Bramwell, "Does that 75 per cent. allow for the urine? "(*Mr. Bidder.*) No, the urine is a different part of "the question. I really do not know that it matters "in the least. (*Q.*) But as a fact your 130,000 tons "becomes 32,000?—(*A.*) It shows the danger of "going from one's analytical results and calculating a "thing theoretically. I have mistaken the wet for "the dry; there is no doubt about it."

(*Mr. Lumley Smith.*) That is excluding the urine.

(*Mr. Bidder.*) Certainly, because the salt in the urine are matters in solution and not in suspension.

(*Witness.*) I say I laid no stress at all upon the 3½ oz., but since the last sitting of the Inquiry I have looked into the matter, and I find at page 132 of Dr. Letheby's book, published in 1872, entitled "The Sewage Question," he shows the total of the soluble organic matters.

8382. (*Mr. Bidder.*) But that is "soluble"; we are talking about suspension?—Dr. Letheby gives you the total amount of solid matter from excreta and other refuse, and he gives, as a matter of fact, suspended matter too; he makes the solid matter come to 0·2044 of a lb. That agrees as nearly as possible with my 3½ oz.

8383. But you are taking wet for dry?—Not at all. I have told you distinctly that the 3½ oz. includes all matter in suspension in the sewage.

8384. Does Dr. Letheby say "dry"?—Yes, this is the actual matter in the water that he gives you. Then again, in that book there are no end of examples

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883

where very much larger quantities of suspended matter are found in sewage than I have given you.

8385. You know that the solid matter would be accounted for to a considerable extent by the road detritus.

(*Mr. Lumley Smith.*) At question 7903 you will find that Mr. Latham spoke of dry matter, not of solid matter.

*Dr. Letheby's book having been examined by Mr. Bidder.*

8386. (*Mr. Bidder.*) You have quoted this book of Dr. Letheby's in confirmation of your statement that the dry matter of fæces was equal to your 3½ oz.; and you referred me to the figure of 0·2044 of a lb.; did it not appear upon the face of the book, that only one-fifth of that was from excreta, and four fifths from other sources?—Certainly. I did not say anything else.

8387. You quoted that book in confirmation of your view upon the dry matter of fæces; did not the book tell you, upon the face of it, that only one-fifth of that dry matter was from fæces?—What I gave was in corroboration of my own estimate. As I said in the case of Croydon it was found that one-tenth of a lb. per head per day was taken out by my sewage extractor, and then there was one-tenth of a lb. which went on to the sewage farm, that gave one-fifth of a lb. of solid matter per head per day in the sewage, and on referring to the solid matter in the sewage found by Dr. Letheby he gives you a little more.

8388. I was cross-examining you as to the amount of solid matter in fæces, and I put it to you that the amount you allowed was a great deal too much, and you quoted that book of Dr. Letheby's as showing 0·2044 of a lb. as being solid matter.

(*Sir John Coode.*) The words I took down were "one-fifth of a pound per head per day solids in "sewage."

(*Dr. de Chaumont.*) It would save time if we understand the matter distinctly; at present we are looking at it in two different ways; as I understood the witness, he said that the total amount of solid matter reduced to complete dryness was about 3½ ozs., but I did not understand Mr. Latham to apply that at all to fæces. It so happens that the average amount of fæces is just about that weight, but including 75 per cent. of water so that there would be something less than an ounce of dry fæces, and the remaining two ounces odd would be the soluble solids in the urine; that was what I understood Mr. Latham to say, is that right.

(*Witness.*) That is quite right.

(*Mr. Lumley Smith.*) The witness said the other day part was in solution.

(*Mr. Bidder.*) You understood Mr. Latham to mean 3½ ozs., including what was in solution. But if you look at the figure, this is the figure relating to what is in suspension. Dr. Letheby says it is true one-fifth of a pound, but he goes on to say that only one-fifth of that is from human excreta, the remainder is from other sources, road detritus, and so on.

(*Sir John Coode.*) The witness says that the amount of dry matter produced per head of the population is 3½ oz. of fæces.

(*Mr. Bidder.*) That is dry matter, and he quotes the book in front of him in support of his figure.

(*Witness.*) I quoted that book in confirmation of the estimate I gave upon the last occasion of the 3½ ozs., as the total solids in the sewage, and I have told you over and over again that these 3½ ozs. have nothing to do with the calculation.

(*Mr. Bidder.*) If you will look at question 7906 there is no doubt about it, because he was asked this question in his examination in chief: "So that your "view is that of fæcal matter alone you get 138,000 "tons, and of general solid matter 197,000 tons," to which the answer is "Yes."

(*Mr Lumley Smith.*) But you must take that with the 7902, which he explains would be made up with other matters.

8388*a*. (*Chairman.*) That would give about one-fifth of a pound for each person?—Yes.

(*Chairman.*) And this table in Dr. Letheby's book shows that there would be one-fifth of a pound of suspended matter for each person.

(*Mr Bidder.*) The table shows that there is one-fifth of a pound as suspended matter, but only one-fifth of that is fæcal.

(*Witness.*) You will recollect you asked me that question, and I declined to answer it. I said it was a question for a chemist, and not for me to say what was soluble, and what was organic matter.

8389. (*Mr. Bidder.*) You have given a great many figures to the Commission with regard to the quantity of sewage, and the ratio of the mixing action, and mixing with the sea water, and so on; now is it not the fact that the sewage when mixed with sea water rapidly disappears as sewage altogether?—It undergoes certainly a rapid decomposition.

8390. And your tables, based upon the assumption that the quantity of sewage put into the river still exists as sewage, are fallacious? — They are not fallacious because I have been most careful to put them together so that there should be no division. I have put in the words "sewage and river water combined," because I knew directly that if I attempted to separate them I should be told that it had disappeared as sewage, therefore I combined them in all the tables, and I show from the tables the rate at which the combined upland water and sewage water pass out of the river together.

8391. But your tables show a certain amount of sewage which you get from observations, and a certain amount of sewage which you know from gaugings comes out of the sewers?—Yes.

8392. But that which comes out of the sewers when it mixes with the sea water rapidly ceases to exist as sewage?—Yes, but that part which we have taken as chlorine is indestructible.

8393. The tables are based generally upon the assumption that there are so many million gallons of sewage coming in at Barking and Crossness, and mixing with so many millions of gallons of water coming over Teddington Weir, and from the other tributaries, and the ratio is based upon that?—The ratio of the chlorine of these samples.

8394. But as sewage you admit that a great part ceases to exist after a time?—I am quite ready to admit that the action of the river is to destroy certain parts of the sewage.

8395. I put it to your experience as a sanitary engineer whether the discharge of the sewage into a tidal river, where it mixes with sea water, is not the safest way of disposing of it?—I do not agree with that.

8396. (*Mr. Abernethy.*) Were you acquainted with the sewage of Brighton formerly?—I do not know much about the sewage works of Brighton, but I have had much experience in the sewage works of sea coast towns, and I know that in some cases the outfalls have been a most frightful nuisance.

8397. Discharging into the sea direct?—Yes.

8398. (*Mr. Bidder.*) That is to say, where you have an outfall which does not take the sewage sufficiently out to sea so that the solid matters are thrown up upon the beach and make an offensive odour?—But in a tidal river like the Thames there must be many days accumulation in the river, which must create a nuisance. I have taken the trouble since the last meeting of the Commission to find out what would be the time during which, owing to the mixing action, the sewage and upland water would remain in the river, and we find that there is an absolute proportion between all these three observations which tends to confirm the correctness of the observations themselves, and it differs very little from a well known hydraulic formula. We find that the length of time is inversely as the seventh root of the fourth power of the quantity coming down the river, consequently in a dry time, when there is only 12 cubic feet coming from a square mile, it would take 63 days for the

sewage to get out by mixing, therefore you would have 63 days accumulation of sewage in the river in a very dry time.

8399. Is it not the fact, where you discharge so that the sewage has the opportunity of mixing with the sea water, that owing to the moving of the water, that is, the action of the motion itself in destroying the organic matter, that forms a perfectly safe method of disposing of the sewage?—I do not say it is always safe; I have mentioned already that one of the objections to the discharge of sewage by means of outfalls into the sea is the frightful nuisance they sometimes create.

8400. Have you ever seen a book called "Sanitary Engineering," by a gentleman named Baldwin Latham?—I know the book well.

8401. I will read a passage to you; it is from page 456. "It may be said in reference to sea out-"falls, that owing to the great mass of water into "which the sewage is ordinarily discharged, and also "owing to the more or less constant movement of "the water, and to the action of the sea water itself "in destroying organic matter, this mode of disposing "of sewage is perfectly safe from a sanitary point of "view, and every trace of sewage discharged under "suitable conditions into the sea soon disappears." I had better read on, as there is something more which is to the point. "When we know by actual experience "that the most perfect mode of dealing with sewage "so as to purify it will not remove more than 80 per "cent. of the impurities present, it is clear that if "one volume of sewage were mixed with four "volumes of water containing no sewage, the mix-"ture would be equal in purity to the purest sewage "effluent. In a sea outfall the proportionate ad-"mixture would be much greater, and is sufficient to "produce the effects of purification observed under "some of the most favourable conditions for securing "a pure sewage effluent." I will just follow that up by asking you, whether at Barking and Crossness the proportion of pure water to sewage is very much greater than three or four to one?—No; there is no pure water at all there.

8402. You stand upon the word "pure." I must admit there is no pure water at all there?—But you know that you have to discharge upon the top of the tide, and the previous sewage has only finished discharging three hours before you discharge again, so it is quite clear that the last sewage that was discharged, must have gone up six miles above the outfall, and therefore, when you discharge on the next high water you actually discharge just upon the top of the previous volume of sewage.

8403. Have you ever taken the trouble to ascertain what the proportion is of sewage to pure water, so to call it, in the Thames at Barking and Crossness, and other parts?—I have given some attention to the matter.

8404. What proportion does a day's sewage bear to the sectional capacity of the part of the river in which it is discharged?—But I should like to answer the question about this quotation first.

8405. Have you anything to qualify the view which you have expressed in that book?—I would first of all desire to observe that this is the concluding passage of a whole chapter upon sea outfalls.

8406. I suppose it is intended to sum it up?—No; I had been pointing out in this chapter the difficulties which often arise with regard to sea outfalls; as you will observe, I had been dealing with the difficulty of solid matter when likely to be deposited. You find first of all that at page 446, I draw attention to the influence of the eddy tide, and show that anything cast within its influence will be deposited upon the shore, then I refer to the influence of sand banks, and then I draw attention upon page 447 to the improper position very often of sea outfalls.

8407. And having said all this, you sum it up by saying what I have read?—I have not finished yet. Then I draw attention to the fact that floating matters and fatty matters are blown back to the shore by the wind. Then I show the damage that is likely to arise to the fisheries from the discharge of sewage. Then you will see that I deal with the action of sea water, especially in setting up decomposition; then the importance of the protection of sea birds, which are the scavengers, which carry away floating matter, and then you will find that this is a sort of reassuring passage to the effect that there may be cases in which sea outfalls properly constructed may be carried out; but you will observe with regard to this mixing, that the solid matter cannot be subject to the mixing action.

8408. Having said all that, is this true or not?—It is perfectly true as far as it goes.

8409. (*Chairman.*) You say they "discharged under suitable conditions into the sea"?—You will observe, as I have previously stated, that the mixing action does not affect the solids; a shrimp is a shrimp whether he is in a pint or a gallon of water, but a pint of salt water or a gallon of salt water, and a gallon of distilled water mixed together make very different mixtures, and my evidence has applied to the solids in suspension. You must not take an isolated passage like that and read it; you must take it with regard to the bearing of what has been said before. Qualified in that way there is not a word in that book which I wish to withdraw, but now that you have brought the book in evidence, I think it would be very desirable if you would draw attention to the part relating to the effect of the rainfall upon the Metropolitan sewers.

8410. (*Mr. Bidder.*) I must ask you to confine your evidence to the passage upon page 456. It is true, is it not, that where you discharge sewage into sea water, and mix it, the decomposition makes it rapidly disappear?—Yes; and creates a frightful nuisance under many circumstances, while it is going on, and in the second place, with regard to the purity point, there is no pure water in the Thames for it to mix with.

8411. But at the same time this is not inconsistent with its being perfectly safe in a sanitary point of of view?—If all the conditions are observed which are set down here.

8412. What is essential, is it the proportion?—It is essential that the sewage shall be effectually got rid of.

8413. But what can be more effectually getting rid of it that getting rid of it by decomposition?—But that is a slow process. If you select a tidal outfall at the proper point it is got rid of at once, but if you put it into the river it is washed backwards and forwards.

8414. I suppose it is the fact that one part of sewage and four of pure water is equal to the purest sewage effluent?—That is taken from the 1st Report of the Rivers Pollution Commission (1868), when they were dealing with the proportion of sewage matter removed.

8415. (*Chairman.*) You mean after the precipitation of the solids?—That is only relating to matters in solution; no amount of mixing can affect the amount of solids in the sewage.

8416. (*Mr. Bidder.*) But you had better keep your eye upon the paragraph because you are getting adrift from it; you say, "We know by actual ex-"perience that the most perfect mode of dealing "with sewage, so as to purify it, will not remove "more than 80 per cent. of the impurities present." there is nothing about matters in solution there?—No; but I have already pointed out that I had dealt with matters floating upon the surface and other solid matter.

8417. But matter floating upon the surface is not matter in solution?—Certainly it is not.

8418. Now you have mentioned the proportion of the mixture of four to one of pure water and sewage as being equal to the purest sewage effluent; what do you say it is at Crossness and Barking?—But the only fresh water coming into the Thames every day is the upland water; it is impossible for any water to come

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883.

in from the sea which is fresh, because the tide can only run up 12·6 miles, and it can only run down 12·6 miles, so that there is an interval between them of the distance of two tides in which no water fresh from the entrance of the river or fresh from the uplands can enter.

8419. If you take only the water over Teddington Weir and the other inflows, it represents a dilution far exceeding four to one, does it not?—No, not in a dry time.

8420. Pardon me; let me remind you that you have told us that 125,000 cubic feet represent the average fresh water and 20,000 cubic feet represent the sewage?—But there is another little calculation you must bear in mind, and that is this, that you only discharge the sewage upon half the water that is passing; that there is one section only of the water that it goes into.

8421. You mean the River Thames is like a chess-board with black and white squares, sewage squares and pure squares, that there are alternate lengths, which are pure water and sewage water?—That would be upon one tide, but the mixing action, of course, immediately disposes of all that. But the fact is, as I say, that while you are really discharging you are discharging only upon a certain portion of the water and not upon the whole volume going down.

Re-examined by Mr. Lumley Smith.

8422. I am not going to take you over the whole field of my learned friend's cross-examination, but I wish to ask you one or two questions. First of all, with regard to the floats you directed, and instructions, as I understand, were given in writing, what float experiments should be made?—Those directions were given in writing and they were approved by Sir Thomas Nelson before they went off.

8423. You personally did not follow any of the floats in a boat or anything of the kind, you had to trust to the persons who were under you?—Yes.

8424. I believe Mr. Birch supervised the observations more particularly than you did; to what extent did you personally take part in them?—I personally occasionally visited the locality while the experiments were going on, but Mr. Birch had the personal charge of the floats. He did not devote his whole attention to the float observations but he did other things as well. He personally assisted us with the gaugings and other matters also.

8425. Did you go down as often as once a day?—No, I only went down occasionally.

8426. For the actual watching of the floats you were, of course, depending upon the men who were with the floats?—Yes.

8427. Mr. Birch, as I understand, lived on board the "Toby" steam tug, and watched the floats?—Mr. Birch had other assistants with him to look after the floats, and from day to day they plotted upon a large scale diagram the course of the floats, and every week the large scale-diagrams were sent to me, and I worked out the observations upon them.

8428. Of course, for the actual watching of each particular float you were dependent upon the honesty and vigilance of the men who were watching the floats?—Certainly; if the men were tampered with or tempted to tie the floats up at night, we could not help a thing of that kind. We have done our best to make the experiments as fair as possible to all parties.

8429. Have you had any complaint made to you, or have there been made any complaints to the City authorities that there had been any neglect of duty?—No. I believe, before the experiments were really commenced, that is to say, before the 17th, a man was found to have tied his float up at night; that circumstance did arise, I know, but it was before the experiments were fairly begun.

8430. As far as you are able to judge from the actual results which have been furnished to you, do you find any difference between the night journeys and day journeys which would lead to any inference that there was a different course of proceeding by night from that by day?—No; I find the fact, which naturally at this period you expect, of a diurnal difference in the range of the tides; and where there is that diurnal difference, the up tides must naturally be the strongest. If you compare the experiments which have been put in by Mr. Phillips, you will find that the day tides are the strongest, and that their up tide at night is very much less than our up tide at night; but the up tide in the day is very much stronger, showing the same features with regard to the diurnal variation of the tides. I have coloured upon this diagram, which has been handed in before, the night tides and the day tides, and I find the average of all the nights is 12·92, and the average of all the days is 12·46, showing that the length of tide has been greater at night, and that there could have been no tying up, as otherwise there must have been a very much smaller run made than was made, and that therefore they corroborate each other in this respect.

8431. And even assuming there may have been some isolated instance of want of care, do you think that the float observations are fairly to be depended upon as accurately stating the effect of the journeys of the floats?—Yes, and especially if you look at the fact that if you deduct, the eight days I mentioned with regard to the D diagram, there remain only 4 per cent. of all the observations which are questioned by the Metropolitan Board.

8432. As regards the case of the float No. 8, distinct directions were given that it should be kept in the direct tidal stream?—Yes.

8433. Does the force of the stream vary very much in different parts of the river?—The float observations show what variation there is in the different parts.

8434. May I take it that the stream varies very much?—In the cross-section it varies immensely, because at the sides the force is very feeble. In the centre, where the tides are moved by the law that the velocity is in the proportion of the square root of half the depth of the stream, there the velocity is considerably greater.

8435. Then, further, I understand that there would be wind, there would be eddies, and there would be accidental influences, and so on, which would affect the motion of the various floats?—Yes.

8436. As far as the instructions to your men were concerned, I understand as long as the float was travelling they were not to interfere with it; if the wind blew it to the side they would leave it there?—If the wind blew it to the side, and it was travelling, they were to leave it there.

8437. And if it got into slack water, what then?—If the float got into slack water, and it was still floating down, then it would be left; it was only to be interfered with if it got foul of a ship, or got aground; it was to resemble a particle of sewage as much as possible.

8438. Did you find that floats which were at various parts of the river progressed differently?—Yes, that is so. If you start floats at different periods of the tide from the same spot, you find they take totally different directions.

8439. Have you found that floats, which were at the same moment in the same cross-section, would pass each other?—That is quite a common thing.

8440. That which was on one side of the river would go faster than the other?—Yes, the float which was in the strong flow of the tide would go faster than the other which was not in the same strength of flow.

8441. Did you find that one of the floats, which had turned one of the corners of the reaches of the river, became susceptible of a different influence?—

Yes, to that drifting action, especially in a very narrow portion of the river.

8442. Then, supposing two floats in the course of a tide to behave in such a way that one goes very near to the corner, and the other goes just round the corner; that would make a very considerable difference in the journey of the two floats?—Yes, that would be so, or it might be that there was a shoal, as there is just above the West India Docks, where the water is very much shallower, and most of the floats which have been pointed out as open to remark have been influenced by that shoal.

8443. Then with regard to the diagram which my learned friend, Mr. Bidder, put into your hand, showing that upon the same day different floats have behaved in a different manner; does that lead you to doubt the correctness of the float observations?—No, I should say that taking them on the whole they confirmed the result of the observations.

8444. You have put in a diagram to-day showing the journeys of each float in which each float is distinguished by a different colour?—It is.

8445. You have explained that each is distinguished by a firm line and by a dotted line?—The firm line refers in all cases to the top of the tide, and the dotted line refers to the bottom range of the tide of the same float, and the singular fact is found that the bottom range of one float often agrees with the top range of another float, because they happen to get in the same part of the river; that is the case in those very instances which have been mentioned by the Metropolitan Board of Works as being discordant, showing that the moment the floats get into the same part of the river and are subject to the same influence, they obey the same natural laws.

8446. Of course that diagram would show it in a minute, but do you find that the discords occur chiefly in a particular part of the river?—They do.

8447. Can you state generally in what part of the river it is that those discordant observations are occurring?—They occur in that part of the river from three miles to ten miles above the northern outfall, or in that twisted and irregular part; every one of the floats implicated has been in that twisted part of the river.

8448. Is that a part of the river where you would expect to find the floats subject to discordant influences?—It is just that part of the river where you would expect to find them subject to discordant influences.

8449. Why is that?—On account of the irregular nature of the channel you would expect to find cross currents, and there are the shoals which I have already mentioned, towards the upper part near the West India Docks, but Mr. More will be better able to give you an account of the physical features of this part of the river than I am.

8450. Now I want to go to a more important question, and that is this: It has been pointed out, and of course it appears upon the face of these diagrams that many of those floats at the end of their stage of probation had actually gone up the river instead of going down?—Yes, but I do not say "at the end of their probation;" they have at a certain period of their course gone up the river.

8451. And of course the observation is patent also that if these floats accurately represented the course of the main body of the water in the Thames, no water ever would have gone out of the River Thames at all?—That is so. There is probably an explanation for that, but that explanation I must say is not my own; it is due to Professor Unwin, whose valuable services we have had upon this matter. He pointed out to me that in all probability it was due to this fact, that in tidal water in going up the stream the water obeys the law of a tidal wave, but in coming down it flows off more generally as a flowing stream. The consequence is that the velocity of the tidal wave being very much greater in deep water the curve of velocity is sharper than it is in the case of the ordinary flow down, where it is flatter, the float in the middle of the river would have a greater tendency to go up upon the tidal wave than it would have to come down again upon the ordinary flow.

8452. Now I wish to ask you your view of the matter. Of course we know that during all the time that the floats were in the water every day a certain contribution came over Teddington Weir into the Thames?—Yes, but I may say that I think Professor Unwin's explanation is the correct one.

8453. (*Chairman.*) You adopt it?—I adopt his explanation.

8454. (*Mr. Lumley Smith.*) What I was going to ask you is whether you could tell the Commission in a compendious way how far these float experiments are a guide or can be treated as a fair standpoint of deduction with regard to the sewage getting out to sea. You have told us over and over again in answer to my learned friend's questions, when he was asking you whether the floats actually represented the voyages of the water that they showed the horizontal oscillation of the tides. I want to know your view as to the extent to which these floating experiments act as a guide to show us how soon the sewage would get out to sea?—With regard to the float experiments themselves, they have nothing to do with showing how soon the sewage gets out to sea; they simply show that where the floats have gone sewage could go as shown by the chlorine tests, for in no case could sea water have gone up the river without the sewage going up with it.

8455. I think my learned friend rather suggested that the sewage was not made of the calibre of these floats; there might be some difference between the movement of large particles and of small particles, I presume?—Yes, some of the sewage goes down at once to the bottom of the river as solid matter, and stops there in the bed of the river.

8456. Sewage matter as soon as it begins oscillating would keep oscillating with the tide backwards and forwards until it got out?—The sewage, or the remnants of sewage, would still keep oscillating backwards and forwards with the tide just as the floats did.

8457. Is there any possible mode of knowing how much is deposited of the solid matter; is there any engineering mode of arriving at it in any way, or is it a matter of observation? — The only mode of arriving at it is to look at the enormous quantity of 200,000 tons a year which is passed in from the sewers, and ask what becomes of that solid matter, and looking at the enormous amount of mud upon the banks the question is answered by the production of that enormous amount of mud.

8458. Now a word or two upon that question of the solid matter. In forming an idea of the amount of solid matter which actually goes into the Thames every year, what is it that you mainly rely upon?—I have relied upon the experiments made by the Metropolitan Board of Works themselves with a very large volume of sewage in the A.B.C. experiments.

8459. That you rely upon?—That I say showed at any rate this, that the solids must have been very much more because it is quite clear, in fact they confess that the sewage upon the south at that period was abnormally weak, and we know that the volume of sewage per head of the population on the south was very much greater than on the north, and that if it gives 57·4 grains per gallon upon the south it must give very much more upon the north, but taking it as we have it upon the south it shows that there is 200,000 tons a year of solid matter thrown into the Thames with the sewage.

8460. Now my learned friend, Mr. Bidder, tried to throw doubt upon your calculation by suggesting that you had done this, that you had not taken upon any particular day the amount of solid matter in effluent water and the amount of solid matter in sewage, but that you had taken the mean in your period of observation of these two amounts of solid matter. Now is not that what in fact is done by Mr. Keates in his report to the Metropolitan Board of Works?—

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883.

Mr. Keates has given the average of his effluent water, and I have taken his average.

8461. The principle of taking an average is adopted in that report?—Certainly it is, and it is adopted by everybody. He is supposed to have written this report with a view to inform us what really took place in these A.B.C. experiments, and he shows us that by taking a certain number of analyses of the sewage and a certain number of analyses of the effluent water, we are enabled to judge what the effects of the process have been, and by comparing those as I have done we come to the figure 57·4 grains of suspended matter to the gallon of sewage.

8462. And you depend upon the calculation you get from that experiment?—I say that if the figures in Mr. Keates' report are correct then my calculation is correct; if Mr. Keates' report is wrong, then my figure would be wrong.

8463. Then, looking at the matter in a different point of view, and corroborating that, if possible, you adopt the mode of taking the $3\frac{1}{2}$ ozs. per head?—I simply mentioned the $3\frac{1}{2}$ ozs. as agreeing so nearly with the total solids in sewage. I did not base any calculation upon them except that I was asked the question how much it would come to, and I gave it; but all my calculations are based upon the one fifth of a lb. per day, which is my own observation, or they are based upon the result of the A.B.C experiment of the Metropolitan Board of Works.

8464. Does the $3\frac{1}{2}$ ozs. represent the amount of dry matter which is produced per head of the population?—Dry matter of all kinds.

8465. That of course includes dry matter from the urine?—It includes dry matter from the urine, but you will find I went further and said that the other solids made up the amount of the $3\frac{1}{2}$ ozs. in place of that which was in solution.

8466. When the $3\frac{1}{2}$ ozs. gets into the Thames a portion of it would go into solution, that is to say, a portion of the original $3\frac{1}{2}$ ozs. of dry matter would go into solution; would there be anything to make up for that loss?—In my mind I had all the solids of other matters which would distinctly make up the same thing.

8467. What is it that goes up to make this loss?—The paper, to a very large extent; there is solid matter from kitchens, grease and things of that kind, which are separate from sewage.

8468. Are those what you meant in your answer to Question 7902, when you said "And of that a part "would be in solution, so it would not be fair to "assume that as all being in suspension, but there are "other matters in the fæcal matter which would take "the place of that matter in solution?"—Yes, exactly, those are the solid matters which are washed from the surfaces of yards and in cleaning floors, an enormous amount of that is carried down. A servant's pail after she has been scrubbing a floor contains an immense amount of solid matter which has been left there by the feet of people, and it all goes down the sewers. There is also, as I say, all the matter from yards and roofs, and streets, it is impossible to intercept the whole of it.

8469. And you take that as going to make up for the loss of the matter in solution?—This matter in suspension goes to make up for the loss of the matter in solution.

8470. Now a question about the vertical range of the tides. My learned friend, Mr. Bidder, drew your attention to page 38 of your report with regard to the length of the ebb and the flood at Teddington, you find that at Teddington the whole tide is said to be 12 hours 13 minutes, the flood being two hours three minutes, and the ebb being said to be 10 hours 10 minutes. I want you to explain the nature of the error, you said it was an error, but that it was an error which was unavoidable?—Yes, it was an error which was unavoidable, because they were scaled off the tidal diagram, and it is impossible in many of the tides to distinguish between flood and ebb. There is an error there of about 12 minutes, which should be added to these tables to make the range correct.

8471. Do you get the full flood and ebb in the 12 hours there?—The tidal period is about 12 hours and 25 minutes, and all the tides should conform to that figure, but when you come to scaling the diagram it is utterly impossible, unless you manipulate the figures in some way, to get it exactly.

8472. At Erith I notice it is put down as 12 hours and 25 minutes, and at two other places the same, whereas at Gravesend it is put down as 12 hours and 24 minutes. Gravesend is, I suppose, a minute wrong?—Yes, these times have been taken out from the diagrams.

8473. And from the nature of the instruments used it is absolutely impossible to get accurately at the time?—Yes, that is so, on account of the small scale of the diagram, for instance in the Gravesend experiment a tide would occupy only an inch and a half in length.

(*Sir John Coode.*) Considering the influence of the wind on the tide one is surprised to find that the figures come out so accurately as they do.

(*Witness.*) Perhaps I might explain another matter about the floats which might lean to some disagreement, when Mr. Bidder put a question about the range being nearer midnight or how I took it, he used the word "tides," which might lead to a misunderstanding. It simply means (as I have divided all these into up and down for morning and evening) that if the float were moving up the river, and the biggest part of the flow was before midnight, it would go as an afternoon tide, and if, on the other hand, the biggest part of the flow were in the morning, it would go as a morning tide. He asked me as to a tide at 3 o'clock in the morning; of course if a tide came to high water at 3 o'clock in the morning that part which went down after the time would be a morning down tide.

8474. My learned friend, Mr. Bidder, was asking you this to-day whether a difference might not be made in your figures if the amount of chlorine in sewage were taken at 20 instead of 10 parts in 100,000, you have taken it at 10 and they suggest it ought to be taken at 20?—Yes.

8475. Have you calculated at all the difference that would be made, assuming that figure to be correct, with regard to the lower reaches of the river?—It would make very little difference in the lower reaches.

8476. The amount of sewage in that water compared to the amount of sea water would be so small that it would be practically imperceptible?—I will have the result worked out and lay the result before you, but as I have stated, in the lower parts it would make very little difference indeed.

8477. Where did you get your amount of 10 parts in the sewage from?—That figure of 10 parts is the figure our chemist will give you as the standard of average sewage, if you took a very strong sewage it might be 20, but taking it on the average, I understand it to be 10.

8478. Have you ever seen it suggested in any of the Reports of the Metropolitan Board of Works that the Thames water was used for flushing the sewers?—Never.

8479. I believe we have had figures given us showing the amount of sewage pumped at Crossness?—Yes.

8480. I believe Sir Joseph Bazalgette has given them to us, and they are published every year?—Yes; but in reference to your previous question, I ought to say that many of the sewers are at such a level that it is utterly impossible to get water into them from the Thames to flush them.

8481. But, as far as the figures are given, relating to Crossness, they give the number of gallons pumped out at the outfalls?—Yes.

8482. They give the amount of sewage and not of the water used for flushing?—Yes; but the important question is, why you should have this enormous difference always upon the south as against the north; you find there is nearly twice as much, proportionally, of

sewage year by year upon the south as there is upon the north. Now, surely, if the sewers require flushing upon the south, those upon the north also require flushing.

8483. They have storm overflows upon the south, have they not?—They have a very large number of storm overflows all the way down the river.

8484. Now, a question with regard to the way in which you have calculated the proportion of chlorine in the combination of river water and sewage. It is necessary, as you have told us, to make an assumption of the quantity of each which is in the mixture; you know what is absolutely the amount of chlorine in the sea, and by mixing water and sewage you can tell the quantity in the mixture?—We know absolutely the quantity of chlorine in the river water, as that is taken, and we know absolutely the quantity of chlorine in sea water, because that is a well ascertained fact. The chemists determine for us the amount of chlorine in the mixture, and there can be no doubt about that.

8485. The amount of chlorine in the mixture is arrived at by taking on a particular day the amount of water coming over Teddington Weir the amount of sewage coming out of the outfalls?—Yes.

8486. My learned friend, Mr. Bidder, suggests that you will not find the exact quantity of water which goes over Teddington Weir upon any particular day of the week mixed with the given quantity of water, which comes out of the sewers upon that same particular day, because the water will not come down from Teddington to the outfall in one day, and that is the fact, because the Teddington water will take some days to get down, and it varies every day, no doubt, in quantity; but taking the quantities upon a particular day is that a fair way to do it?—Yes; I have already explained that if you put a given quantity of water into the river at Teddington it immediately displaces a like quantity of water further down the river; the tidal impulse only takes one hour and twenty minutes to travel from London Bridge to Teddington, and exactly the same kind of impulse is transmitted by the water entering the channel at Teddington, but, although, it may not be the particular particle of water which came in at Teddington, yet it pushes an equal amount forward further down.

8487. Would the difference between one day and another, taking an ordinary average flow at Teddington, make any difference practically in the mixture as regards its being a fair average mixture?—Of course, if you could suddenly jump from extreme low water to extreme flood water, it would make a difference in the proportions of the mixture, but it would not make a difference in principle, as you would have an equal quantity of water pushed out to that which you had coming in. You may imagine really a long trough filled with clear water, if you pour in a pint of ink at the upper end, a pint of ink will not run out at the lower end; a pint of clear water will run out, but the impulse has been transmitted, which causes the clear water to run out.

8488. At any rate would the difference be effective in any way compared with the vast body of sea water in the lower reaches to disturb the calculations?—No. You will see from the calculation I put in (showing the absolute correctness of the tables I have put in) that, taking the relative volume of tidal water at Southend and upper river water, and taking sea water with a mixture of river and sewage water whether in the lower reaches or the higher parts of the river, there is practically no difference.

8489. I would not ask you any more questions upon that, because I find my learned friend, Mr. Bidder, at question 7548 said "In the lower reaches, where the proportion of chlorine reaches hundreds of grains, the relative proportions of fresh water and fresh "water and sewage are not important." That is so, is it not?—It is.

8490. You were asked a question which involved two hypotheses, one of which was, assuming that the sewers were made for the then population, with the margin of taking double their average flow; then the next hypothesis was, supposing the maximum flow was only 40 per cent. above the average, would the sewers then be competent to take the sewage of the population?—I have already shown that the whole of the calculations which I have put in have been based upon the figures given by the Metropolitan Board of Works.

8491. Have they anything to show that the sewers are ample for the population?—The very figures that I have taken, their own figures, show that the northern outfall never was big enough for the population.

8492. Now you were asked a question about the rainfall. My learned friend suggested that those were new observations which were invented for the purpose of this inquiry. Now, those are in your book, are they not?—Yes, I think it is desirable that you should have some information as to the operation of the rainfall in the London sewers.

Mr. Norman Bazalgette objected to the introduction of this, as being new matter.

The Chairman ruled that the evidence was admissible.

(*Witness.*) This is what I have already written with regard to the London sewers, beginning at page 52 of my work on Sanitary Engineering:—"Although "the sewers of London are calculated to carry away "rain at the rate of a quarter of an inch in 24 hours, "and it is stated in Sir J. Bazalgette's paper on the "'Main Drainage of London,' that there are not "more than 25 days per annum when the rainfall "in 24 hours exceeds this quantity, it must be "apparent that the sewers of London are only cal-"culated to convey away one-hundredth of an inch "of rainfall and subsoil water per hour, in addition to "the sewage, and whenever the rainfall exceeds this "rate of fall, although the total fall in twenty-four "hours may not equal a quarter of an inch, great "inconvenience must naturally be occasioned in the "low level districts, especially if the rain occurs at "periods when the sewers are tide-locked, and cannot "consequently get relief by the storm water overflows. "Experience in connexion with the metropolitan "sewers has shown that the allowance made for rainfall "and subsoil water in the low-level districts is not "sufficient, and consequently some of the low-lying dis-"tricts which are below high-water mark get flooded, "the reason being that, in the low-level districts, "when there is a rainfall exceeding the quantity the "sewers are constructed to contain, and at the same "time the storm-water outlets are tide-locked, the "low-lying districts cannot get relief, and are con-"sequently flooded. To obviate this inconvenience, "the Metropolitan Board of Works have determined "that, when the low-level sewers are filled to excess, "and no relief can be afforded by the storm-water "outlets by reason of the state of the tide, the ex-"cess, or what would, under similar circumstances in "a high-level sewer, flow direct to the Thames, "shall, in case of the low-level sewers, be pumped "into the river. From the discussion which took "place at the Institution of Civil Engineers, after "papers had been read on the drainage of London "and Paris, it appears that in 1857 Messrs. Bidder "and Hawksley found in the case of London, that "with a rainfall of 2·90″ in 26 hours, Savoy Street "sewer delivered 64·5 per cent., Ratcliffe Highway "sewer 52 per cent, while Lieut.-Colonel Haywood "found in the same storm that London Bridge sewer "discharged 53 per cent. Lieut.-Colonel Haywood, "in April 1858, had gaugings taken of the same "sewer, 'when ·24 of an inch of rain fell in an "'hour and a half; he then found that 74 per cent. "'of the total quantity ran off, leaving 26 per cent. "'to be absorbed or evaporated. Of a rainstorm "'of ·54 of an inch, in five hours in June 1858, "'there was delivered into the Irongate sewer, which "'drained an area entirely paved and built over, as "'much as 94·5 per cent. of the total rainfall; and "'of all the storm gaugings he had made, that was "'the greatest per-centage he ever knew discharged

*Mr. B. Latham, M. Inst. C.E.*

6 Feb. 1883.

" 'by a sewer. In August 1858, with a rainfall of " '·48 inch in one hour and two-thirds of an hour, " 'he found only 78 per cent. of the total quantity " 'discharged into the Irongate sewer.'"

8493. (*Mr. Norman Bazalgette.*) Will you read on to the words "one tenth of it to the sewers"?—"The "author has found that the amount of water con- "tributed in various districts depends very much "upon the character of the surface which receives "the rainfall. In districts in which the geological "character is porous, the rain contributed to the "sewers is very small. For example, in the case of "Croydon, where the geological formation principally "consists of gravel overlying chalk, the amount of "rain contributed by a storm of ·72 of an inch in "12 hours in October 1865 did not yield more than "one-tenth of it to the sewers." That only shows that in the case of Croydon these rains affect the sewers to nothing like the extent they do in London; yet in Croydon I have shown that a normal rainfall has produced a fluctuation in the sewers which is vastly more than anything the London sewers can deal with.

8494. (*Mr. Lumley Smith.*) Have you anything to say with regard to the chalk wells?—The wells further inland than Grays show that they have not that same amount of chlorine in them, and samples of water taken the same day show that they are not influenced in the same way. Near Erith the distant wells yield 1·4 in 100,000 of chlorine, showing that that is the standard amount of chlorine in the inland districts, and that it is only when they come within the range of the tide that there is shown to be an increased amount of chlorine directly due to the effect of the tidal water.

8495. (*Sir John Coode.*) You have given the Commission some figures with regard to the increased range of the tide of late years, and you stated that you considered that that increased range was due to the improved sectional area of the channel by dredging operations. I thought you gave that with some hesitation. Is that based upon any information and figures as to the amount of improvement and deepening in the channel?—I know there is an improvement in the river. I have seen the figures of the enormous dredging which has taken place of late years.

8496. But it is all assumption, is it, or have you made any comparison as to the increase of range corresponding with the increase of the dredging?—Yes, I have. I am able to show that there is now an increased velocity up the river. The range in 1858, that is to say, the average speed of the wave travelling up, from the Nore to London Bridge, was one hour and 40 minutes, whereas now it is one hour and 30 minutes.

8497. In making your observations had you any tide gauges?—We had recording tide gauges at Deptford, Erith, Gravesend, and Southend, and we read them every day.

(*Sir John Coode to Mr. Lumley Smith.*) I cannot help thinking that if you have observations on tide gauges made at different parts of the river, a diagram plotted showing the surface of the river, and the water gradients at high, low, and half tide, both flood and ebb, would throw some considerable light upon these apparent eccentricities which have been remarked upon.

(*Mr. Lumley Smith.*) We have had one prepared I think at high tide, and at low tide. I do not know whether that will answer your purpose.

(*Sir John Coode.*) We want it done at a considerably distorted scale, at say four miles to an inch, and an eighth of an inch to a foot vertical; if you could give us the high and the low water surfaces at high water, low water, and half water, flood, and ebb, that would throw considerable light upon the subject of the supposed discrepancies and discordancies. I mean in a longitudinal section.

(*Mr. Lumley Smith.*) We will endeavour to have it done.

8498. (*Colonel Ewart to the Witness.*) You have referred in your evidence to the storm outlets and overflows; have you taken any specimens of the discharges of them?—I have seen them discharging, but have not taken any samples.

8499. You have not had any specimens analysed?—I believe they have been analysed, but I am by no means certain. I have seen the one at Blackfriars Bridge, the one at the end of the Fleet, and it always strikes me that what is discharged by it is much more filthy and much more concentrated sewage than that discharged from the main outfalls, and they are now making other overflows the effect of which will be to bring the rainfall and sewage combined to a greater extent into the upper parts of the river.

8500. In the course of these investigations have you been much upon the river yourself?—Yes.

8501. With regard to your table on page 18 of the Minutes of the Sixteenth Day, I see that you calculate what will be the probable increase of population up to the year 1901; in the north it amounts to an increase of about one fourth, and in the south, I think, to an increase of more than half; but inasmuch as the metropolitan areas upon the north and south are not elastic, must not that be dependent upon whether or not there is room to build?—Of course the tendency under those circumstances is to aggregate a greater number of persons in a house; it is shewn that there is a greater number of persons in a house upon the north than there is upon the south. The proportion is eight persons to a house in the north and seven in the south.

The witness withdrew.

Adjourned to to-morrow at half-past 12 o'clock.

# TWENTIETH DAY.

## Wednesday, 7th February 1883.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.

FRANCOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, ESQ., F.R.S., *Secretary.*

Mr. JAMES MANSERGH, Mem. Inst. C.E., F.G.S., F.M.S., examined.

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

8502. (*Mr. Balfour Browne.*) You are a member of the Institution of Civil Engineers, and of various other societies, and have been in practice as a civil engineer for a good number of years?—Yes, I have for 25 or 30 years.

8503. I think your practice has been almost exclusively in designing and carrying out works for the disposal of sewage and for water supply?—Yes.

8504. During that long period you have reported and advised upon a very large number of water supply works and sewage works?—For about 200.

8505. Both for corporations and other public bodies at home and abroad?—Yes.

8506. How many works may you have carried out?—In about 60 different towns.

8507. In order to give the Commission an idea of the extent to which you have been engaged, would you mention some of the towns with which you have been connected?—Bedford, Grantham, Tunbridge Wells, Reading, Southport, Middlesbrough, Lincoln, St. Albans, Burton-upon-Trent, &c.

(*Chairman.*) We will take all those for granted.

8508. (*Mr. Balfour Browne.*) In many of the cases which you have just been mentioning has the disposal of sewage been the object which you have been called in to advise about?—Yes, I have been called in to drain the towns, and to dispose of the sewage.

8509. Have you been connected with works for the disposal of sewage by precipitation in tanks, irrigation of and filtration through land, and its discharge into tidal rivers and estuaries?—Yes.

8510. I think you were one of a number of engineers who prepared schemes for the Lower Thames Valley Drainage?—Yes.

8511. And you received one of the three premiums awarded for that matter?—Yes.

8512. And you were engaged before the Commissioners in the Inquiry of 1879–80 as to how to dispose of the sewage of the Lower Thames Valley?—Yes.

8513. And you have acted as an arbitrator with reference to the pollution of the River Tees?—Yes; there was a question in the year 1878 as to the pollution of the River Tees by the discharge of the sewage of Middlesbrough into it, and I was one of the arbitrators engaged in that case.

8514. I believe you gave evidence on the long inquiry into the mud in the Thames?—I did. I was one of the witnesses for the Conservators upon that inquiry.

8515. In the course of that inquiry you had opportunities of becoming acquainted with the Thames?—I had. I went down the Thames a good many times, and got up a lot of information upon the subject, and became very well acquainted with the whole state of the case.

8516. Especially, I think, in connexion with the outfalls at Barking and Crossness?—Yes, that was so.

8517. For the preparation of this case have you been associated with Mr. Baldwin Latham and the other witnesses in getting up the facts which are to be laid before the Commission?—I have.

8518. And you are acquainted with the data which have been collected for the purpose of throwing light upon this matter?—I am.

8519. And I think that, in conjunction with Mr. More, you have prepared a longitudinal sections of the Thames, from Teddington to Southend?—Yes.

(*The same were handed in. See Appendices W. 1 to 4.*)

8520. Will you just tell the Commission how many cross sections you made of the river for the purpose of making that longitudinal section?—Between Teddington and Southend I have made 133 cross sections between something above high water and something below low water. The surveys of the Thames Conservators are below low water, that is to say, their soundings are all taken below low water, and in order to get cross sections of the river up to high water those sections were taken.

8521. Then by the use of these cross sections, and also by information supplied by Mr. More from the surveys of the Thames Conservancy, have you got at the cubic capacity of the river, and is that shown upon those sections?—It is for four tides—there are two spring tides and two neap tides, and of the two tides, one of each had a small quantity of land water in, and the other had a large quantity of land water in.

8522. I see there is a table handed in with those cross sections which explains them?—Which gives the capacity.

(*The following Table was handed in. See page* 282.)

8523. There are four longitudinal sections?—Yes.

8524. Marked A, $A^1$, B, $B^1$?—Yes.

8525. Will you take the first two of those, A1, and A?—The first two of those were spring tides, A1, being that of the 1st of October 1882, the height of which by Roberts's Tide Table was 29 feet 2 inches on the sill of the Shadwell lower entrance of the London Docks.

8526. I see that on one of those occasions there was a flood in the river?—Yes.

8527. And the other was about the ordinary amount of tide?—Upon the 1st of October tide there was 179,000 cube feet per minute running into the Thames from Teddington and the tributaries below to Southend—on the other spring tide, that on the 30th and 31st of October, there was running in 1,303,924 cube feet—about from six to seven times as much.

8528. Those figures appear upon the table of reference?—They do.

8529. The third tide, B, I see was a neap tide upon the 6th of October, 1882?—That was so.

8530. What was the height?—The height upon the tide table was 24 feet 6, and the quantity of land water coming in between Teddington and Southend, including Teddington, was 143,220 cube feet per minute. Then on tide $B^1$, which was also a neap tide, of the 4th of November, there were 24 feet 8 inches on Roberts's tide table, but on that occasion 708,694 cube feet of land water a minute were coming into the Thames.

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

TABLE of CAPACITY of RIVER THAMES as shown on LONGITUDINAL SECTIONS marked respectively A¹, A, B, B¹.

N.B.—On these sections the line dividing the light and dark blue colours represents the surface of the water from Teddington to Southend, *at the time of low water at Southend* for each of the tides, and the upper line bounding the dark blue represents the surface of the water from Teddington to Southend *at the time of the following high water* at Southend.

The dark blue colour shows therefore the quantity of water which entered the river both from the Thames above Teddington and the tributaries between Teddington and Southend, and from the sea, during the time of flood tide at Southend, and is called "tidal water" in the table;—the light blue colour is called "low-water content."

| | Low-water Content. Light Blue. | Tidal-water, including inland and sea-water, entering during flood tide. Dark Blue. | Total Content of River. Teddington Southend. |
|---|---|---|---|
| | Cube feet. | Cube feet. | Cube feet. |
| TIDE A¹.—Spring tide of 1st October, 1882 (29 ft. 2 in. on Roberts' Tide Table), with relatively small quantity of land water coming in, viz.:—179,099 cube feet per minute from Thames above Teddington and tributaries below. Time of Low Water at Southend - - - - - - 9.25 a.m. Do. High Water do. - - - - - 3.8 p.m. Duration of flood tide at Southend - - - - - 343 minutes. | | | |
| Low-water Content between Teddington and Barking - - - - - | 1,337,062,090 | | |
| Do. do. between Barking and Southend - - - - - | 17,736,971,361 | | |
| Tidal Content between Teddington and Barking - - - - - | | 1,720,178,285 | |
| Do. between Barking and Southend - - - - - | | 18,576,054,395 | |
| Total Low-water Content between Teddington and Southend - - | 19,074,033,451 | | |
| *Total Tidal Content between do. do. - - - - | | 20,296,232,680 | |
| Total Content of River—Teddington to Southend - - - - - | | | 39,370,266,131 |
| *N.B.—Of the 20,296,232,680—61,400,087 cube feet are land water, and 20,234,832,593 cube feet are from the sea. | | | |
| TIDE A.—Spring tide of 30th–31st October, 1882 (28 feet 2 in. on Roberts' Tide Table), with relatively large quantity of land water coming in, viz.:—1,303,924 cube feet per minute from Thames above Teddington and tributaries below. Time of Low Water at Southend - - - - 9.20 p.m., Oct. 30th. Do. High Water do. - - - - 3.15 a.m., Oct. 31st. Duration of flood tide at Southend - - - 355 minutes. | | | |
| Low-water Content between Teddington and Barking - - - - - | 1,547,279,429 | | |
| Do. do. between Barking and Southend - - - - - | 17,433,521,276 | | |
| Tidal Content between Teddington and Barking - - - - - | | 1,693,050,308 | |
| Do. between Barking and Southend - - - - - | | 18,905,450,703 | |
| Total Low-water Content between Teddington and Southend - - - - | 18,980,800,705 | | |
| *Total Tidal Content between do. do. - - - - | | 20,598,501,011 | |
| Total Content of River—Teddington to Southend - - - - - | | | 39,579,301,716 |
| * N.B.—Of the 20,598,501,011—462,893,020 cube feet are land water, and 20,135,607,991 cube feet are from the sea. | | | |
| TIDE B.—Neap tide of 6th October, 1882 (24 ft. 6 in. on Roberts' Tide Table), with relatively small quantity of land water coming in, viz.:—143,220 cube feet per minute from Thames above Teddington, and tributaries below. Time of Low Water at Southend - - - - - - 1.7 a.m. Do. High Water do. - - - - - 7.37 a.m. Duration of flood tide at Southend - - - - - 390 minutes. | | | |
| Low-water Content between Teddington and Barking - - - - - | 1,603,666,012 | | |
| Do. do. between Barking and Southend - - - - - | 21,551,899,564 | | |
| Tidal Content between Teddington and Barking - - - - - | | 1,025,235,800 | |
| Do. between Barking and Southend - - - - - | | 9,888,777,284 | |
| Total Low-water Content between Teddington and Southend - - - - | 23,155,565,576 | | |
| *Total Tidal Content between do. do. - - - - | | 10,914,013,084 | |
| Total Content of River—Teddington to Southend - - - - - | | | 34,069,578,660 |
| *N.B.—Of the 10,914,013,084—55,855,800 cube feet are land water, and 10,858,157,284 cube feet are from the sea. | | | |
| TIDE B¹.—Neap tide of 4th November, 1882 (24 ft. 8 in. on Roberts' Tide Table), with relatively large quantity of land water coming in, viz.:—708,694 cube feet per minute from Thames above Teddington, and tributaries below. Time of Low Water at Southend - - - - - - 1.0 a.m. Do. High Water do. - - - - - 7.10 a.m. Duration of flood tide at Southend - - - - - 370 minutes. | | | |
| Low-water Content between Teddington and Barking - - - - - | 1,457,944,341 | | |
| Do. do. between Barking and Southend - - - - - | 19,539,139,333 | | |
| Tidal Content between Teddington and Barking - - - - - | | 1,020,497,637 | |
| Do. between Barking and Southend - - - - - | | 9,476,250,993 | |
| Total Low-water Content between Teddington and Southend - - - - | 20,997,083,674 | | |
| *Total Tidal Content between do. do. - - - - | | 10,496,748,630 | |
| Total Content of River—Teddington to Southend - - - - - | | | 31,493,832,304 |
| *N.B.—Of the 10,496,748,630—262,216,780 cube feet are land water, and 10,234,531,850 cube feet are from the sea. | | | |

WESTMINSTER,
January 15th, 1883.

8531. How much was that over the mean—nearly six times the mean, I think?—Yes, about that.

8532. Now as I understand you have just described in words what those sections show graphically to some extent?—To some extent. I have not described what the lines mean.

8533. There are two colours upon this chart or section, the one dark blue and the other light blue?—Yes.

8534. What is the meaning of the line dividing those two colours?—The line dividing the light blue from the dark blue is the line showing the surface of the water from Southend to Teddington at the moment of low water at Southend; you may call that a synchronous line. Taking the exact time of low water at Southend, we have obtained from the six recording gauges the height at the site of those gauges at the same instant, and that line represents the surface of the water. Similarly the upper border of the dark blue shows a synchronous line of high water at Southend.

8535. So that taking the lower and the higher, does the boundary of the dark blue show the capacity between the two tides?—That shows the quantity of water which has entered the river between low water at Southend and high water of the succeeding tide; of course that includes the water coming in from the sea and the water coming in from the land.

8536. What is represented by the light blue colour?—The light blue colour represents the water in the river at Southend, at the time of low water at Southend.

8537. The dark blue, you say, represents the amount of water which has entered between low water at Southend and the next high water at Southend: from what sources has that water entered the river?—From the sea and from the land, from the Thames over Teddington Weir, and from all the tributaries between Teddington and Southend, and from the sea.

8538. And I may say, although I have only this one before me just now, that the same is done with relation to the whole four longitudinal sections?—That is so.

8539. In tide $A^1$, the tide being spring with a little land water, because the land water was only 179,000 cube feet, the quantity of water in the river below the low water synchronous line (that is the light blue) from Teddington to Barking outfall was what?—The low-water content between Teddington and Barking upon the A1 tide, light blue, was 1,337,062,090, cube feet. The low-water content between Barking and Southend was 17,736,971,361 cube feet.

8540. Then those two figures together represent the light blue upon the longitudinal section?—Yes, that is the whole of the low-water content at that time between Teddington and Southend. You will see it added up at the bottom—the whole low-water content was 19,074,000,000 cubic feet.

8541. Now just tell us the same figures, referring to the dark blue—what comes into the river from the three sources you have described, land water, Teddington Weir, and tributaries between Teddington and the sea?—The content of the dark blue, that is water coming in at flood tide between Teddington and Barking, was 1,720,000,000 cube feet (I need not trouble you with the small figures) and between Barking and Southend it was 18,576,000,000 cube feet.

8542. Making a total of how much?—Making a total of 20,296,000,000. Then the grand total of the whole—the whole content of the river between Teddington and Southend, at high water at Southend, was 39,370,000,000.

(*Sir John Coode.*) For all practical purposes it is about half and half—that is near enough for our purposes.

8543. (*Mr. Balfour Browne.*) Of that 20,296,000,000, how many cube feet of fresh water would represent the water coming over Teddington Weir?—61,400,000.

8544. Where does that appear upon the table?—It appears just at the bottom of the tables—it is marked "N.B."

8545. Does that 61,000,000 cubic feet represent not only the Teddington Weir water but all the land water?—The Thames coming over Teddington Weir, the River Lea, and the Cray, and all the tributaries between Teddington and Southend.

8546. Then the whole content of the river you have given?—Yes, that is 39,370,000,000.

8547. Now will you turn to the longitudinal section A, please. Section A was the one where the greater quantity of land water was coming in?—The A tide is the 30th and 31st of October tide.

8548. As we dealt last time with the light blue, first, perhaps we had better adopt the same course again. What was the amount of water between Teddington and Barking at low water?—The low-water content between Teddington and Barking was 1,547,000,000 cube feet.

8549. And from Barking to Southend?—From Barking to Southend it was 17,433,000,000 cube feet; the total low-water content was 18,980,000,000 cube feet.

8550. Again, as we have dealt with the whole of the light blue upon this section, would you just deal with the figures of the dark blue?—Now going to the tidal content between Teddington and Barking, it was 1,693,000,000 cube feet; between Barking and Southend it was 18,905,000,000 cube feet; the total being 20,598,000,000 cube feet. Of that 462,893,000 cube feet were land water.

8551. Just before we leave $A^1$ and A, there seems to be very little difference between the total content of the river upon those occasions?—A very little difference indeed. The total content of the river was 39,579,000,000 cube feet; only about 200,000,000 more than the tide in which the water was so very much less.

(*Mr. Michael.*) Practically, we may say it is one to one.

8552. (*Mr. Balfour Browne.*) Now the B tide instead of being a spring was a neap?—The B tide was a neap, the tide of the 6th of October.

8553. And there was upon that occasion comparatively little land water coming in?—143,000 cube feet per minute came in over Teddington Weir and from the tributaries.

8554. I want the same quantity above the synchronous line between the light and dark blue?—The low-water content between Teddington and Barking is 1,603,000,000 cube feet, and the low-water content between Barking and Southend is 21,551,000 000 cube feet, the total of the low-water content being 23,155,000,000 cube feet.

8555. Comparing that with the spring tide, the content is greater at low-water neap than it is at the spring tide?—Yes, the tide does not ebb out so far.

8556. Now with regard to the other figures, what comes in with the tide?—Between Teddington and Barking the tidal content is 1,025,000,000 cube feet, and between Barking and Southend it is 9,888,000,000 cubic feet.

8557. What is the total?—The total tidal content is 10,914,000,000 cube feet.

8558. What is the gross total of those two?—34,069,000,000 cube feet, and of the water coming in during the flood-tide 55,855,000 cube feet were land water.

8559. The amount of tidal water coming into the river on the neap tide seems to be a little more than half of what comes in upon the spring?—Yes, a little more than half of what comes in upon the spring.

8560. Will you just go over the same figures with regard to $B^1$ tide?—$B^1$ tide was the tide of the 4th of November when there were 708,694 cube feet of land water coming in between Teddington and Southend.

8561. I see that in all these cases you give the times of the tide?—The figures I have given below in the footnote are simply the figures I have given

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

above multiplied by the number of minutes of the flood-tide at Southend.

8562. Now will you give the low-water content between Teddington and Barking upon this occasion?—1,458,000,000 cube feet.

8563. And between Barking and Southend?—Between Barking and Southend it was 19,539,000,000 cube feet, making a total of 20,997,000,000. The tidal content between Teddington and Barking was 1,020,000,000, and between Barking and Southend it was 9,476,000,000, making a total of 10,496,000,000, the gross total content of the river being 31,493,000,000. Of the tidal water the dark blue, 262,216,000 came in from the land.

8564. We have already pointed out that there is but little difference between the grand totals in the case of the two spring tides, but it does appear that there is a considerable difference in the case of the two neap tides—what is the difference?—There was one-twelfth more water in the river at high water upon the 6th of October than upon the 4th of November, although upon the 4th of November there was $5\frac{1}{2}$ times as much land-water coming in.

8565. I see that upon the 4th of November, which is the smallest tide, there were 708,000 cubic feet of land water going in as against 143,000 cubic feet of land water going in upon the 6th of October?—Yes, per minute.

8566. With regard to those two tides B and $B^1$, from looking at the tide table, what would you have expected them to vary in height?—The tide table said two inches.

8567. (*Mr. Michael.*) There is five times as much relative quantity of land water coming over in tide $B^1$ as in tide B, and yet the total quantity calculated at high water of the B tide is more than on the 4th of November, the B1 tide?—That I am going to explain now. Now this anomaly is accounted for from the fact that on or before the 6th of October the wind had been blowing for some time from the quarter between east and north, which would tend to keep both the high water and low water up; whereas on and before the 4th of November the wind blew somewhat strongly from the quarter between south and west, which would have the contrary effect. If you look at the diagram giving the force of the wind and the directions of the wind you will see that that is the cause.

8568. (*Mr. Balfour Browne.*) The diagram giving the force of the wind is already upon the tables put in by Mr. Baldwin Latham?—Yes.

8569. The fact is that upon one day, the 4th of November, there were five times as much water coming in from the river from inland sources as on the 6th of October, but the total amount was one-twelfth more on the 6th of October than it was upon the 4th of November, is that so?—That is so.

8570. Your explanation of that seeming anomaly is that the wind in the one case was favourable and in the other adverse?—That is so.

8571. Those sections that we have just been speaking of show that the water impelled into the river from the sea upon a high spring tide is twice as much, roughly speaking, as on a low neap?—Yes; you see that by the figures; in the one case it is about 20,000 million cube feet and in the other about 10,000 million cube feet.

8572. Do they indicate anything to your mind with regard to the effect of a large quantity of land water coming down the river?—Yes; that tends to raise low water from Teddington to London Bridge, and a little below, but it does not affect anything much beyond that point. It is the tidal wave which fixes the height of the tide, modified as I have stated by the wind.

8573. You have handed in this table which the Commissioners have before them to give all those figures in case they have not taken them down?—Yes; I have marked that table M1, that is the Capacity Table.

8574. Do you also produce a longitudinal section of the river from Teddington to Southend which shows the mean line between absolute high water and low water heights?—Yes; I have put on the section a mean line which has been deduced from a number of observations of the self recording gauges at Southend, Gravesend, Erith, Deptford Cattle Market, Chelsea, and Teddington.

8575. How long do those observations extend over?—The number of tides at Southend was, high water, 127, and low water, 126; at Gravesend, high water, 125, low water, 133; Erith, high water, 148, and low water, 148; Deptford, high water, 137, low water, 137; for Chelsea I have not the numbers; Teddington, high water, 141, and low water, 142.

8576. My learned friend, Mr. Bidder, wants to know before we leave table M1, whether the heights upon Roberts's tide table are the observed heights or the calculated heights?—They are the calculated heights as given upon the table.

8577. (*Mr. Bidder.*) You have not given us the heights which were observed upon those occasions?—I have not given you them, but I have given you the content, and the figure is given upon the table.

8578. (*Mr. Balfour Browne.*) You are going to give the heights now, I believe. In the section you have handed in there is a line shown in black, is there not?—There is.

8579. And that shows the mean you have just described?—Yes.

8580. What was the height of that line at the various points, beginning at Southend?—The mean between high and low water, obtained from the large number of observations which I have given, was at Southend O.D. + 1·89 feet, at Gravesend + 1·94 feet, at Erith + 1·96 feet, at Deptford Cattle Market + 1·98 feet, at Chelsea + 4·00 feet, at Teddington + 11·00 feet.

8581. And upon that section are the sectional areas of the river below the mean line shown?—They are shown, and they are also given upon Table M2.

(*The following was handed in.*)

RIVER THAMES.

*Mr. J. Mansergh, F.G.S., F.M.S.*

7 Feb. 1883.

SECTIONAL AREAS.

| No. of Cross Section. | Place. | Sectional Areas at Mean Tide, Levels. | Sectional Areas on 14th September 1882. | | Sectional Areas on 22nd September 1882. | | Sectional Area on 30th November 1882. | |

8582. Upon this Table M 2 are the heights you have just given above Ordnance datum shown?—Yes, the heights are all given upon the table as well as the areas.

8583. Will you give the sectional areas at mean tides?—They are given in square feet. At Teddington it is 1,601 square feet, and then you will see below that the height I have already named is given O.D. + 11·00; Chiswick, 5,102 square feet. Then there is given the height at Chelsea, O.D. + 4·00; St. Paul's Pier, 12,358 square feet; Deptford, 22,280 square feet, with the height below it. Then there is one at No. 74 on my longitudinal section of 25,969 square feet. North Woolwich, 31,257 square feet; Barking, 43,993 square feet; Crossness, 50,200 square feet; Erith, 70,475 square feet; Erith piers, 69,558 square feet; Purfleet, 62,503 square feet; section 99, 65,903 square feet; Gravesend, 96,674 square feet; Gravesend "Ship and Lobster," that is just a little below, 110,299 square feet; Hope point, 169,856 square feet; Egypt Bay, 204,802 square feet; Southend, 526,443 square feet.

8584. Now you have prepared, I know, a longitudinal section showing the absolute high and low water heights; is that the same section as is before the chairman, or is it another?—It is another section; the sections are not put in, but the areas are all given below the heights.

8585. The areas in the further column of this table M2 are the areas at absolute high and low waters of the tide?—Yes, upon the 14th and 22nd of September and the 30th of November, the days upon which the chlorine samples were taken, the areas are given and the heights from which they have been calculated are given. I do not think it is worth while reading the whole of the table.

(*Sir John Coode.*) The table is perfectly clear and explicit.

8586. (*Mr. Balfour Browne.*) Have you carefully considered all the facts and figures which have been produced in this case?—I have, and also those which were got together in the Mud Case.

8587. And are you in a position to support the position of the Port Sanitary Authority that a nuisance is caused by the discharge of the sewage of the Metropolitan Board of Works at Barking and Crossness?—Yes, I think that at certain times of the year, in very dry weather, there must be a very great nuisance.

8588. You said in "dry weather," do you mean dry or hot weather?—Dry and hot weather.

8589. Before going to the outfalls, let me ask you if you have anything to say as to the river between bridges?—Yes, between bridges it is evident that a gradually increasing nuisance is threatened. Although it may be admitted that a great improvement between bridges has resulted from the taking of the sewage down to the Barking and Crossness outfalls, a growing nuisance must arise because of the increase of the population having already overtaken the calculations that were made in 1858 when the scheme was laid down.

8590. That is the cause, but what is the effect?—The effect is that the storm overflows must come into action more frequently than was then contemplated.

8591. And when the storm overflows come into action the sewage gets into the river up here instead of down at Crossness?—Yes, no doubt.

8592. Have you anything to say with regard to what I may call the Grosvenor Road Pumping Station?—I believe that that pumps direct into the river very frequently, but I have not seen it myself.

*Mr. Bidder* objected to the evidence.

8593. (*Mr. Balfour Browne.*) At any rate, your evidence is this: that the nuisance from the discharge at the storm overflows is an increasing nuisance?—It must be.

8594. And that because the population of the metropolis has already overtaken and surpassed the number for which the works were originally designed?—Yes, the fact of an increase in population of 500,000, tells in two ways, not only in increasing the actual quantity of sewage, but in another way. If there are 500,000 people more in London now than was reckoned upon, then there must be a very large area now covered with roads and buildings which was then open country, and from which a very small proportion of the rain falling would then have got into the sewers. Now instead of getting 5 or 10 per cent. you may get 60 or 80 per cent. of the rain falling off the roofs and the roads and paved areas, and that tends to gorge the sewers, and cause overflows.

8595. That you look upon as an addition to the sewage proper?—I do. Then take the case of Hampstead, a district I know very well, a district in which for the neighbourhood of London the roads are very steep, the rain that falls gets into the sewers in a very short time indeed.

8596. Whenever the sewers become gorged, then of course the storm overflows come into action and carry out the sewage into the river?—Yes.

8597. Have you anything to say with regard to the south side. A smaller provision I think was made

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

upon the south side for the rainfall on account of the sparse population?—Yes, a smaller provision was made upon the south in 1856, or when the scheme was designed, than upon the north. Over some part of the area only an eighth of an inch was intended to get in instead of a quarter of an inch.

8598. Would you tell us the number of the population that the works were originally designed for. Mr. Latham gave it in his evidence as 3,448,500 persons?—Yes, I have taken that figure from the Report of the 6th April 1858.

8599. Speaking broadly, how many people may now send their sewage into the outfalls?—About half a million more, taking the two sides.

8600. (*Mr. Bidder.*) You say "may now"?—And do. There is a very small area I believe which is not drained into the sewers, but nothing of any extent.

8601. (*Mr. Balfour Browne.*) What percentage would that be of excess over that which was calculated for?—About 14 per cent. in excess of what was calculated as being the number to be provided for by the works.

8602. And the effect of that, as you have clearly pointed out, would be that there is less room in the intercepting sewers for the sewage, and that consequently the storm overflows have been called much more frequently into action than they would have been if their capacity had been more liberal in the first place?—Yes.

8603. You have already explained that this operates in two ways:—first of all, the increased population contributes a much larger amount of sewage; and secondly, that that which was open land formerly is now built upon, and contributes very much to the gorging of the sewers?—Very much so indeed.

8604. You have stated 14 per cent. as being the excess of population over the original provision. Can you give us any parallel city to illustrate your percentage?—You may say that the sewage of a city as large as Liverpool or Manchester has been added to the metropolis beyond what was intended.

8605. Therefore recurring to your remark with respect to the state of the river between bridges, something has happened or is happening between bridges which was not contemplated when the Metropolitan Drainage Scheme was laid out?—That is so, and that must be a growing evil as the population increases.

8606. Is there anything worthy of consideration in the fact that the subsoil water is getting into the sewers on the southern side of the Thames?—According to the figures which have been given, there appear to be about 50 gallons per head getting into the sewers upon the south side as against 30 gallons upon the north, and I can see no other mode of explaining it than that it arises from leakage as Mr. Latham stated.

8607. (*Sir John Coode.*) You do not mean 50 gallons a head in addition to what gets in upon the northern side, but 50 as against 30?—Yes, 50 gallons altogether.

8608. (*Mr. Bidder.*) I suppose that is derived from the same source as Mr. Latham stated?—Yes; I do not suppose for a moment that that leakage gets into the main intercepting sewers, because I know they were exceedingly well done; but that it gets into some of the local contributing sewers.

8609. (*Mr. Balfour Browne.*) Your view is that it does not get into the main intercepting sewers but into the contributing sewers; but at all events, wherever it gets in, there it is?—It gets in; I take it from Sir Joseph Bazalgette's own statement.

8610. (*Mr. Bidder.*) Would you show us where Sir Joseph Bazalgette says that it gets in?—It was stated by him upon the Mud Inquiry.

8611. (*Mr. Balfour Browne.*) It is in the evidence of the 12th July, page 735. (*To the witness*) Now if that 20 gallons per head is in the sewer, that adds another means of gorging besides the two that you have already described?—Yes, it amounts to adding the sewage of a population equal to two-thirds of the number of people, being 1,308,738, now using the sewer; that is to say, to adding an amount of sewage equal to that of 872,000 people upon the south side.

8612. (*Sir John Coode.*) But not adding that amount of pollution?—No; adding that amount of sewage, it puts into the sewers, a sewage equal to that of two-thirds of the population that is now using them.

8613. (*Mr. Balfour Browne.*) Even if it is only water put into the sewers it will tend to send the sewage out up here?—Yes, it charges the sewers to such an extent that they cannot hold the quantity of rainfall that was contemplated, and therefore the storm overflows come into action more frequently.

8614. It also, of course, has the effect of making the sewage weaker in dry weather?—Yes, no doubt.

8615. Having dealt with the river between bridges, let us go down to the outfalls between Barking and Crossness; how does the excess of the population operate upon the outfalls there?—First, of course, in increasing the actual volume of sewage beyond what was provided for.

8616. That is the first thing?—Yes; secondly, it affects the reservoirs. The reservoirs were calculated to hold their sewage during nine or ten hours of every tide, so that it should be only let out during 2½ or 3 hours. If the volume of sewage has thus increased, then the storage is practically diminished, and the discharge must go on during a longer time.

8617. To put it shortly, the reservoirs must be too small?—The reservoirs must be too small.

8618. Although I suppose when they were built the Board calculated upon some increase in the population?—Certainly they provided for a very large increase in the population, but the population has surpassed that estimated increase, and to a large extent the reservoirs must be too small now.

8619. And therefore, there again, whether it is really sewage that gets into the pipe or merely clean subsoil water, the capacity of the reservoirs will tell, because the discharge will require a longer period?—Yes.

8620. Have you a third conclusion?—I am now referring to the conclusion of Messrs. Bidder, Hawksley, and Bazalgette, in their report. I refer to their remark, that they provided for three and a half millions of people. I think I have said all upon that point which I desired to say.

8621. According to the view which I understand you to present to the Commission, it was never contemplated in 1858 that the works then intended to be constructed would be sufficient and satisfactory for a population so much in excess of the then population as we have now?—That is so. Messrs. Bidder, Hawkesley and Bazalgette say, in their report of 1858, that the plan "admits of indefinite extension and "adaptation to future necessities," and I think the time has already come when the works want adapting so as to alter them to present circumstances.

8622. I think we now pass to another branch of the subject?—I think the question of deodorisation ought to be gone into, as it was clearly intended that something should be done in that direction.

(*Chairman.*) I think that would fall in with the second part of our inquiry.

(*Mr. Balfour Browne.*) We are not going into any proposal for the future, but are only proposing to show what was intended to be done when these works were sanctioned.

8623. (*To the witness.*) You have examined the reports of Sir Joseph Bazalgette?—I have read all the reports, I think.

8624. And especially those of April, May, and September, 1856?—Yes; I find in Sir Joseph Bazalgette's reports in April, May, and September, 1856, upon the northern and southern outfalls, that he seemed to think then that deodorisation would not be necessary if the outfalls were made so low down as at Barking, that is the tenour of his reports.

8625. After the report of the Government Referees, dated the 30th July, 1857, Sir Joseph Bazalgette had

associated with him, as we have heard so often, Messrs. Bidder and Hawksley?—Yes.

8626. And those gentlemen reported to the Metropolitan Board of Works upon the 6th of April, 1858; you know what they said?—They went further than Sir Joseph Bazalgette did in his own reports; they talked of deodorising the sewage, and of spending 20,000*l.* a year in so doing.

(*Chairman.*) I think it would be best to refer to the report at once.

8627. (*Mr. Balfour Browne.*) The report contains an estimate at page 145. I think you will find these words:—"The sewage due to the present population "of the metropolis, including some rainflow, amounts "to about 80,000,000 gallons per diem"?—They go a little further than Sir Joseph Bazalgette did.

8628. The report proceeds: "the cost of the "application of the lime process to this quantity of "sewage would therefore be 40,000*l.* per annum; "but as in the case of the Metropolis there is "clearly no advantage, practical or theoretical, to be "obtained by the use of this process during the six "colder months of the year, we estimate the extreme "cost at only 20,000*l.* per annum. If, however, the "sewage be discharged at Barking Reach and "Crossness Point, into deep water, and with the "earlier portion of the descending tide, we believe "the process will not be needed during even the "hotter months, except, perhaps, under very "occasional and very exceptional conditions of the "river." That bears out what you said that they went a little further than Sir Joseph Bazalgette?—Yes. Then the Referees criticised that report, and Messrs. Bidder, Hawksley, and Bazalgette replied again upon the 20th of July, 1858, with what they called "brief observations," and in this document they went still further.

8629. Will you refer to the "brief observations" upon the 7th page, and read the eighth observation?—This is a curiously worded paragraph:—"The "referees, without being aware of the system upon "which the terminal reservoirs are intended to be "worked, object to their size." Then they go on to say:—"They will contain a tide full of sewage "proper, including maximum drainage, but during "rains it is intended to use them as depositing "reservoirs, allowing the clarified water to pass "slowly through the internal chambers in warm "weather in a fully deodorized state, but in cold "weather without being more than sufficiently limed "to carry down the suspended matter. The reservoirs "were designed on this principle, and we have no "doubt will work effectually." I read that to mean this,—that the sewage is to be so treated in warm weather that it would be discharged in a fully deodorized state, and that in cold weather it is to be so far treated that the suspended matter would be precipitated and retained and not sent into the river.

8630. That is your understanding of the paragraph?—I cannot make it mean anything else. Then there are certain Conclusions to this paper, and the 5th, 6th, and 8th of those conclusions bear out the interpretations I have given.

8630*a*. Will you just refer to anything that you think does that?—The 5th conclusion is:—"That "under the peculiar local circumstances of the "metropolis, it is more economical to pump and "deodorise (wholly or partially) than to convey the "sewage by deep channel gravitation to Sea "Reach." The 6th conclusion is:—"That the "expense of deodorising has been greatly magnified "in the referees' answer to our report." The 7th is:—"That the process of deodorisation may be, and "is at Leicester, so conducted as not to give off any "noxious emanations." The 8th conclusion is:—"That the supernatant liquid will not become putre-"scent in the river." From that I judge that it was clearly intended that the solids should be precipitated, and that only the supernatant liquid should go into the river.

8631. Now upon the 12th August 1859, the last having been 1858, Dr. Hofmann and Dr. Frankland, reported to the Metropolitan Board of Works?—Yes, they did; they reported as to the "selection from the "various schemes proposed for the deodorisation of "sewage of a process combining both efficiency and "economy." They were specialy requested to report.

8632. These gentlemen, I think, made a recommendation, but what you want to refer to is something on page 7 of their report of the 12th August 1859, what do they say?—They say: "The sewage "discharged at Barking Creek and Crossness Point "would probably not require deodorisation, except "during the hot season of the year, say, during three "months." Then they go on to give the cost and they say: "Supposing the deodorisation to be "effected by perchloride of iron, the disinfection of "this portion of the sewage at the present rate of "flow would involve an expenditure of 11,620*l.* for "the three months. We are, however, of opinion, "that in practice the sewage discharged into the "river at this distance from the metropolis would "rarely require deodorisation for so long a period as "three months. In fact, we are not without hope "that the sewage, supposing it to arrive at these "outfalls in a condition similar to that in which it is "at present discharged from the King's Scholar's "Pond sewer, would, *when properly freed from "suspended matter*, only require deodorisation under "particularly unfavourable circumstances." They clearly contemplate the removal of suspended matter.

8633. I think they go on to say:—"It remains "only to draw particular attention to the importance "of discharging the sewage into the river as free "from mechanically suspended matter as possible"?—Yes.

8634. "We have found that this suspended matter, "when separated even from the deodorised sewage, "rapidly passes in warm weather into a state of "active putrefaction"?— Yes, they emphasise that very much; they emphasise strongly the recommendation that the solids should be removed, therefore, both the engineers and chemists and all the advisers of the Board at that time contemplated the taking out of the solids before the sewage was discharged.

8635. They contemplated that, but they also contemplated that in hot weather there should be deodorisation?—They did.

(*Chairman to Mr. Balfour Browne.*) We do not wish to stop you in any way, but you will bear in mind that this is merely evidence of the opinions which were expressed by scientific men as to what would or would not be necessary 25 years ago. We do not like to stop you, but you may take it as shortly as you can, because it is only remotely connected with the question which we have to inquire into. It is doing us service to call our attention, in passing, to these matters, no doubt they might be very useful in cross-examination hereafter.

(*Mr. Bidder.*) Those were the speculations of scientific men before the work was done as to what would be the result; but it is hardly worth while to go this roundabout way to get at it when we can give what the actual results are.

(*Chairman.*) We had been rather waiting for you to take the objection.

8636. (*Mr. Balfour Browne to the witness.*) Whatever those opinions were, I want to ask your opinion, do you think that the advice of the engineers and chemists was good sound advice, and ought to have been acted upon?—Yes, I do.

8637. And is it your view that the discharge of sewage in its crude untreated condition into the river creates a nuisance which ought to be avoided by some such process as that indicated in the opinion of the engineers?—Yes, I do; a nuisance not only by its discharge into the river at the time, but subsequently on account of the deposit of organic matter in the river itself, and on the mud banks which become exposed at low water. The sewage discharge, at the time of discharge, is itself a nuisance greater of course in very

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

hot weather, but a subsequent nuisance may arise from the fact that some of the organic matter is deposited in the river which, in very hot weather, comes up to the surface and causes an abominable nuisance.

8638. And those are the facts as they have been described by some of the witnesses?—Yes.

8639. Looking at the information which has been got together by the Port Sanitary Authority, and looking to the physical condition of the river, do you think that it points necessarily, altogether apart from the evidence which has been given before this Commission, to the creation of a nuisance?—I do.

8640. What do you found that opinion upon—do the float experiments, in the first instance, give you any information upon which you can found that opinion?—Yes.

8641. What do you say with regard to the float experiments from 1 to 7, taking the northern outfall?—They show of course what everybody knew to a certain extent, that the water after passing down the river is brought up again, and must bring with it sewage—they show also that at certain times of the tide near the top and bottom of the tide the velocity of the current is much less than it is in the intermediate part of it, that is to say, in the middle of the tide, and during that time my opinion is that a considerable deposition of the solids takes place.

8642. The fact that there is a time of rest as it were in the river gives an opportunity for the solids going to the bottom?—Yes; if you were to plot any of those diagrams you would find that for an hour or two at the top of the tide the curve is a very flat one—that as it begins to run down it becomes sharper, and then it is flatter towards the bottom, and as the tide slacks it gives a great opportunity for the deposit of solids on the bed of the river.

8643. That you get from the diagrams?—Yes, the diagrams would show that if they were drawn upon a larger scale.

8644. You say that altogether apart from any deductions which were given by Mr. Latham?—Yes.

8645. Is there any other remark which you want to make about these experiments?—No, I do not know that I do—it has all been so fully gone into before.

8646. What you say with regard to the flat curve at the top is also true as to the flat curve at the bottom?—Yes.

8647. That both at high water and low water the river at Barking is to some extent a settling tank?—Yes, and any point in the river above and below Barking, when the water comes to a condition almost of rest.

8648. Is another result which you arrive at, from these float experiments, that a segment of the river is polluted to an undue and abnormal extent and becomes a local nuisance to the neighbourhood on the banks?—Clearly that must be so. Take the northern outfall; when the sluices are open at the top of the tide, and when for half-an-hour there is practically no current—the whole river is covered with sewage and for a short time it causes a great nuisance to the locality.

8649. I understand that in your opinion, in estimating the rate at which the sewage goes out to sea, the float experiments alone, taken without conjunction with the chlorine tests, would give you no information?—No, practically not as regards the progress to the sea—the progress to the sea has been worked out entirely from the two factors, the displacement by upland water and the displacement by mixing with the sea water.

8650. And the rate of progression must be calculated from those data and not from the float observations?—Not from the float observations.

8651. The land water, as you say, acts simply by displacement?—Yes.

8652. The influx and reflux of the tide has an entirely different action upon the carrying of the sewage out to sea?—Yes, the influx of the tide diminishes the area available for the passage of the land water, and therefore increases its velocity.

8653. Supposing there was no sea water flowing in and out, but that the Thames was a river falling into a lake or tideless sea, then you could calculate the rate of progress to the lake by the land water coming over Teddington Weir, and the sectional area of the river?—Yes, if it had to pass into a lake, and the channel of the river were the same slope and the same sectional area all the way down, the progress down the river would be the same day by day.

8654. But if the sectional area were increased, the progress would be diminished?—Yes, in an inverse ratio to the increase of the sectional area.

8655. So that the further you got down the tidal river the slower the progress would become, whereas, as a fact, it becomes quicker?—Yes, it would be slower; the same quantity of water would be displaced at the low end, but seeing that the sectional area was larger, the distance passed through would be so much shorter.

8656. Suppose that enough water comes in at the head of the channel in a day to fill five miles of river, and the river were 50 miles long, there would be the same amount of water pass out of the river at Southend, only it would be water that had passed in at the head 10 days before?—Clearly, the water that comes in to-day would displace water which came in 10 days before at the upper end.

8657. And of course of the same bulk?—The same volume of water would go out, but not the same length in the river channel.

8658. The channel of the river is not of equal sectional area throughout, but widens, as you have said, and deepens at the same time?—Yes.

8659. You have told us that under those circumstances, looking at the displacement alone, the rate of progression would inversely diminish?—Yes.

8660. Suppose the sectional area of the last half mile near the mouth were 10 times the sectional area of the top five miles, then the length of the segment of water displaced would be only half a mile instead of five miles long?—Yes, that is so.

8661. That makes the mere displacement theory perfectly clear?—Yes.

8662. And in calculating the rate at which sewage is carried out to sea, though you take in another element, yet you must always use displacement as a factor?—Yes.

8663. The amount of water coming in over Teddington Weir and other sources varies every day?—Yes.

8664. Now the second factor is, what in Mr. Latham's evidence has been called "mixture" and which is due to the entrance into the river of Lea water?—Yes.

8665. I want you to explain your view of this to the Commission. This mixture takes place whenever the fresh and the salt water come together, I suppose?—Yes.

8666. Is it facilitated by the stirring action of currents and eddies?—The mixture takes place by the eddies, the currents, the wind, and all things of that kind.

8667. (*Sir John Coode.*) And the screws of steamers, I suppose, have something to do with it?—No doubt they would help to mix the waters.

8668. (*Mr. Balfour Browne.*) The way in which these elements induce progression to the sea can, I think, be explained by means of a diagram which you have prepared?—It has helped to explain it to my mind (*shewing a diagram*). Let us suppose that the 100 black spots upon what I call the first position are molecules of fresh water surrounded by salt water, and that then they are moved down the river in the course of a tide to the second position. In the course of being moved down and coming up again upon the next tide they are surrounded by a larger number of particles of salt water, or have aggregated around them a larger amount of salt water. Then on their return up the river into position 3, having been so increased in size, they cannot get into the position they held at first, and therefore some of the body

must overflow down the river. (*Explaining the same upon the diagram.*) I may say these areas are plotted quite hypothetically.

8669. (*Chairman.*) Why is it that they cannot get into the same position coming up?—Because they have so much more sea water around them, and occupy a greater bulk.

8670. (*Sir John Coode.*) Do you mean each dot to represent a molecule of sewage or of fresh water?—Of fresh water, and not of sewage.

8671. (*Mr. Balfour Browne.*) As I understand, it is not that these 100 dots could not occupy the same place, but that, having got down further, they aggregate and associate themselves with thousands of salt particles, and the body then cannot go into the same space, but only a portion of it; a portion overlaps, and the progression is to be measured by the position of the mean centre moving down the stream?—That is so; it is only a way of explaining how it arises. The *measurement* of the progression is made by means of the chlorine tests.

8672. Of course this is not the measurement at all?—No, that is only a diagram that was made to explain it to one's own mind.

(*Sir John Coode.*) I think we had better take the chlorine tests, for whatever they may be worth, in preference to that hypothetical diagram.

8673. (*Mr. Balfour Browne.*) Mr. Mansergh has adopted the chlorine tests implicitly. (*To the witness.*) You have worked upon the chlorine tests with regard to the mode of progression?—I have adopted them; I did not invent them at all. Whoever did, has, in my opinion, done great service, but I have adopted them.

8674. This is merely to show hypothetically how, diagrammatically, it can be made to appear?—Yes.

8675. The very next thing I was going to argue was that the extent of the mixture between fresh water and sewage and salt water is to be measured entirely by the chlorine test?—Yes, exactly. I think the chlorine determinations give a mode of measuring the mode of progression which was never thought of before.

8676. You have told the Commission that if it were merely by displacement in a lake without tidal influences the rate of progress would be diminished. As a fact, I think the chlorine tests show that the rate of progress is increased?—Yes, the rate of progress is increased, because the land water has not to displace the water in so large a section. Already any section of the river is occupied by sea water, and therefore the land water has to get through in a smaller section, and must therefore get through in a shorter time. There is no impounding of the water; there is no more water in one month than in another month.

8677. If the sectional area were the same all through the 50 miles, it would progress at the same rate every day?—Yes.

8678. If the sectional area is increased, the progress is diminished?—Yes.

8679. If the sectional area is diminished the progress is increased?—Yes.

8680. Now I understand you to say that the incoming of the tide has the effect of diminishing the sectional area?—It has the effect of diminishing the sectional area which the fresh water has to pass through.

8681. And therefore the incoming of the tide, as a physical fact, has the effect of expediting the progress of the fresh water and the sewage to the sea?—Yes.

8682. You have prepared some other tables, I think, which you wish to lay before the Commission?—I have prepared M. 3*a*, M. 3*b*, M. 3*c*, and M. 3*d*.

(*The following were handed in. See pages* 290, 291, 292, 293.)

8683. First with regard to M. 3*a*, will you kindly proceed to explain that table?—The object of preparing these tables was to make out the time in which the land water with the sewage in it would progress to the sea, and I have worked upon somewhat different lines from Mr. Baldwin Latham for the purpose of explaining it, I think, in a clear way, and of checking our relative results.

*Mr. J. Mansergh. M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

8684. You have taken, I see, two days, the 14th of September and the 30th of November?—The 14th of September was a day on which there was a comparatively small quantity of land water, and the 30th of November was a day on which there was a comparatively large quantity coming down.

8685. Those were two of the days when the chlorine tests were taken from the samples?—Yes, there was another day, the 22nd of September, but I thought those two enough to deal with.

8686. In this table M. 3*a* I see the river is divided into 12 divisions, six above Crossness and six below?—Yes, I take Crossness as the middle point, because there the whole of the sewage has come into the river, and there happen to be 30 miles below Crossness and a little over 30 miles above Crossness. I have divided the river below Crossness into six divisions of five miles each, and above Crossness into five divisions of five miles each, and one of 7·15 miles adjoining Teddington. In the first column I put the chlorine found by analysis at Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, Barking, Erith, Gravesend, and Southend. Then I have interpolated, to the best of my judgment, the mean chlorine in that first division which I have called, in the table, the sixth division above Crossness. You will find it both at high water and low water. Taking high water, the sixth division gives 3·2, the fifth 4·7, the fourth 107·7, and so on; you will find the interpolated chlorine under the *length* of the division in each case. Then in column No. 3. I give the content of the river in each division; that is taken out from the cross sections; I have taken out a large number of cross sections, so that this content represents at high water upon the 14th of September very nearly,—as nearly as can be,—the quantity of water in each of the divisions.

8687. And those would correspond with the longitudinal sectional divisions?—Yes, in the sixth division you will find 171,000,000 cube feet, and in the fifth division 264,000,000 cube feet.

8688. The sixth division is the 7·15 miles?—Yes. Now, going to the first division below Crossness, you get a content of 2,342,000,000 cube feet, and in the division immediately above Southend 14,430,000,000 cube feet; in each of those five mile divisions you have the content in the third column. Then, working from the chlorine, in the fourth column I got the percentage of sea water.

8689. Is it not well to call attention to the second item upon the sheet, the quantity of water coming over Teddington weir upon that date?

(*Chairman.*) We have had that in the other table.

(*Mr. Balfour Browne.*) But it may be material here, I think.

(*Witness.*) That is stated here as 119,990,880 cube feet in 24 hours, and the quantity of sewage I have estimated as coming in at Barking and Crossness is given below, being 14,760,000 cube feet at Barking and 11,240,000 cube feet at Crossness in the 24 hours. Now column 4 gives the percentage of sea water in each of those divisions; there is nothing in the first, it is too small to be given; in the second division it is 0·2, and in the division immediately above Southend 95·7, showing a gradual increase of salt water as you progress down the river. Then in the fifth column the actual quantity of sea water is given as worked out from these percentages; in the fifth division above Crossness it is $\frac{1}{3}\frac{1}{0}\frac{1}{0}$th of the whole quantity. In the last division above Southend you get 95·70 of sea water, so that you get out of 14,430,000,000 cube feet, land and sea water, 13,809,000,000 cube feet of sea water.

8690. Is that column worked out from the first by the percentage of sea water?—Yes. Now column No. 6. gives the percentage of upland water.

8691. There is an important note to that, the column is headed "Percentage of upland water, in-

(M 3A.)

## RIVER THAMES, 14th September 1882.

Quantity of Water coming over Teddington Weir 119,990,880 cube feet in 24 hours.

TABLE showing the RATE of PROGRESS towards the SEA due to the UPLAND and TIDAL WATER.

*N.B—The River is divided into Six divisions of 5 miles each from Crossness down to Southend, and Five divisions of 5 miles each and One of 7·15 miles from Crossness up to Teddington.*

The measured quantity of Upland water entering the River in each division is calculated as coming in at the upper end of that division,—the sewage discharged at Barking is calculated at 14,760,000 cube feet, and at Crossness 11,240,000 cube feet in 24 hours.

Upland water is taken as containing 1·7 parts of Chlorine, Sewage 10 parts of Chlorine, and Sea Water 1,961 parts of Chlorine per 100,000 parts.

* It is assumed for the purpose of calculation, but *not admitted*, that there is no Sewage in the River above Barking.

The *mean* of Columns 13 in the High and Low Water Tables is to be taken as the time of progress towards the sea, on the assumption that the conditions prevailing on the 14th September are maintained during the whole period.
From Teddington to Southend the mean time is 48·93 days. From Crossness to Southend the mean time is 31·85 days.

Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.

(M 3c.)

## RIVER THAMES, 30th November 1882.

**Quantity of Water coming over Teddington Weir 685,936,800 cube feet in 24 hours.**

TABLE showing the RATE of PROGRESS towards the SEA due to the UPLAND and TIDAL WATER.

*N.B.—The River is divided into Six divisions of 5 miles each from Crossness down to Southend, and Five divisions of 5 miles each and One of 7·15 miles from Crossness up to Teddington.*

The measured quantity of Upland water entering the River in each Division is calculated as coming in at the upper end of that Division,—the sewage discharged at Barking is calculated at 14,760,000 cube feet, and at Crossness 11,240,000 cube feet in 24 hours.

Upland water is taken as containing 1·7 parts of Chlorine, Sewage 10 parts of Chlorine, and Sea Water 1,961 parts of Chlorine per 100,000 parts.

* It is assumed for the purpose of calculation, but *not admitted*, that there is no Sewage in the River above Barking.

The *mean* of Columns 13 in the High and Low Water Tables is to be taken as the time of progress towards the sea, on the assumption that the conditions prevailing on the 30th November are maintained during the whole period.
From Teddington to Southend the mean time is 16·59 days. From Crossness to Southend the mean time is 12·78 days.

*M. J. Manergh, M. Inst C.E. F.G.S., F.M.S.*
7 Feb. 1883.

Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.

; Feb. 1883.

"cluding sewage"?—Including sewage when the sewage comes in. I take it that the sewage comes in at Barking.

8692. And it is assumed, for the purpose of calculation, that there is no sewage above Barking. Of course it is not admitted, but you take it so for the purpose of calculation?—Yes, I do not deal with sewage above Barking at all. I disregard it for the purpose of calculation.

8693. (*Sir John Coode.*) You do not admit that there is no sewage above Barking?—I do not admit it, but I disregard it.

8694. (*Professor Williamson.*) You calculate your chlorine upon the assumption that the sewage does go in above Barking?—I have dealt with the chlorine in the sewage when it goes in at Barking, and not above.

8695. (*Mr. Balfour Browne.*) The 6th column shows you, as there is "Nil" in the fourth and fifth columns, that there is a percentage of 100·00 of upland water at Teddington?—Clearly, the difference between column No. 4 and No. 6 is the difference between the 4th column and 100. For instance, 5·40 in the 4th column is opposite 94·60 in the 6th column. Then from that is worked out the quantity of fresh water and sewage in each division. At Southend the fresh water, including sewage, is 4·30, the sea water being 95·70. Then in the next column is the quantity of upland water coming in in each division. You will see the quantity of water coming over Teddington Weir is given at the top of the sheet as 119,990,880 cube feet, but I put it down under the head of "Teddington" at 122,860,800 cube feet, simply because there are tributaries coming in within that first division, and I assume this as all coming in *at* Teddington. I thought it was the simpler plan, so that in the 6th division you get 122,860,800 cube feet per day.

8696. You have passed over the "quantity of upland water and sewage in each division"?—That is got out from the percentages, as in the other case.

8697. I suppose columns No. 5 and No. 7 added together make No. 3?—Yes. Then column No. 8 shows the quantity of upland water at the top of each division, and you will see, when we get down below Crossness, that the Barking contribution of sewage is brought in, and when that is brought in, the chlorine in the upland water is amended by the addition of the 10 parts of chlorine per 100,000 in the sewage. Then the ninth column shows the percentage of sewage in the upland water and sewage; that is to say, the quantity of sewage I have estimated to come in at Barking is 14,760,000 cube feet, which is 10 per cent. of the quantity in the eighth column, opposite "Barking." In the eighth column, the sixth line, the figure you will find is 148,000,000 cube feet, and the sewage coming in at Barking is 14,760,000 cube feet, so that the sewage is practically 10 per cent. of the total; then, as the Crossness sewage comes in, that percentage is increased, and then it is diminished again because there is an addition of clean water coming in from some tributary, and the percentage diminishes from 16 to 15. Then the tenth column would represent the quantity of liquid that has come out of the sewers; that is column 7, multiplied by column 9, and divided by 100. Column 11 shows the percentage of sewage in the whole content of each division; it gives the percentage of sewage in the whole combined body of sea and fresh water. Then the twelfth column gives, in the upper part of it, the progress from Teddington through each of the divisions, and that is obtained by column 7, which is the upland and sewage being divided by column 8, the quantity of water coming in for each division.

8698. (*Mr. Bidder.*) In point of fact, column 13 represents the progress downwards due to displacement only?—No, due to everything; it is due to the sectional area of the river being diminished by the presence of sea water.

8699. If you look at the head of column No. 12, you will find it says, "Time taken to progress through each division, column 7 divided by column 8," therefore it is simply displacement?—Yes, it is displacement, but it is only calculated into that column 7.

8700. It is the rate due to displacement?—But if it were taken into the whole volume, column No. 3, it would increase the number of days immensely. It is all to the good for you.

8701. (*Mr. Abernethy.*) I see that in the second division above Crossness the percentage of sewage is nil?—I do not admit that there is no sewage above, I only assume it for the purpose of these calculations.

(*Mr. Lumley Smith.*) Of course you will not take that as being the fact, it is merely assumed for the purpose of the calculations.

8702. (*Mr. Balfour Browne.*) If it were simply displacement, as my learned friend Mr. Bidder would indicate by his question, you would have divided column 3 by column 9?—Yes, and then the time would have been very much increased.

8703. But as it is displacement and mixing, you divide column 7 by column 8?—Yes.

8704. The result giving you the total progress towards the sea?—The coming in of the sea water tending really to diminish the sectional area, and consequently the content in any division of the river. I divide that by the quantity passing through.

8705. (*Mr. Bidder.*) But this does not take into consideration any acceleration of the downward progress by mixing?—I beg pardon, it does clearly, if you were to deal with the whole content of the river, this number of days would be very largely increased, it is only because I divide column 8, which is the quantity coming in into the diminished content of the river caused by the infusion of the sea water that we get this more rapid rate.

8706. (*Mr. Balfour Browne.*) The twelfth column shows the progress through each division and the thirteenth column shows the total length of time taken?—Yes, and I have divided that into two parts, first of all I give the progress from Teddington to Crossness, time taken 23·98 days, and then from Crossness to Southend 30·73 days.

8707. Every one of the figures you have been giving refers to absolute high water?—They refer to high water upon the 14th of September.

8708. (*Mr. Bidder.*) That column No. 1 which is headed "Chlorine found by analysis," is the actual number of parts of chlorine which the chemist discovered without any inference at all?—Yes. Then, in the second column, there are my interpolations for the mean of the mass in each division.

8709. (*Mr. Balfour Browne.*) That is only a calculation?—Yes, I can show you how I have done it, but I have taken it as fairly as I possibly could.

8710. Now we will pass to low water upon the same date?—With regard to low water upon the same date the table is made out in exactly the same way.

8711. I do not think we need go through all the columns, but let us take one?—I will take column No. 11, on Table M 3b, showing that in the division above Crossness there was 8·70 of sewage in the river, and below Crossness 11·70. Of course by "sewage" I mean what comes out of the sewers. Then at low water the rate of progress from Teddington to Crossness is 10·17 days, and from Crossness to Southend 32·98 days. I had better give you the mean of that. Dealing with Crossness to Southend, which is the important thing, adding high and low water together, and taking the mean, the mean time taken would be 31·85 days. That agrees practically with Mr. Latham's mean, which is 31·34, so that we agree as nearly as can be.

8712. Although you arrive at it from a totally different calculation?—It is a calculation different from the beginning except the chlorine tests.

8713. Have you worked out the mean of those two last columns?—It is not printed here, but I have given my mean of high and low water upon the 14th of September as 31·85 days according to these figures, and 31·34 days according to Mr. Latham's.

8714. The chlorine test was also taken upon another occasion?—I have taken it for the 30th of November.

8715. The table is carried out upon that date in exactly the same way?—Yes, only that we begin with 686,000,000 cube feet coming over Teddington Weir instead of 120,000,000 cube feet. The effect of that very much larger quantity of land water is to increase the rate of progress to the sea and to diminish the quantity of sewage in any section. From Crossness to Southend the mean of high and low water is 12·78 days.

8716. That of course is not upon the tables, but it is the mean between the two tables?—Yes; and the mean which Mr. Latham worked out was 12·65 days.

8717. So that there again you are practically agreed?—Practically, we are; we could not be nearer together.

8718. Have you any remark to make in conclusion upon this part of the case?—The moral to be deduced from that is this, that the thing which keeps the river comparatively clean is a flood such as we had upon the 30th of November. When a big flood comes down it accelerates the progress to the sea very considerably, but the converse of that is true, that whenever there is a very small quantity of water coming down the river in very hot weather, then the number of days will be very largely increased, from 31 up to 50 or 60 possibly.

8719. The chlorine tests are good, but only good for matters that will mix?—They are only good for matters that will mix.

8720. They are not good for solids?—Some of the suspended matter no doubt would partake more of the nature of the movement of the floats.

8721. And therefore, although this does really show what would happen to the fluid sewage, it does not show what would happen to the solid matter?—No, I do not think it does; solids must deposit very largely at the head and tail of the tide.

8722. (*Mr. Abernethy.*) This quantity of sewage relates entirely to what is discharged at Barking and Crossness?—Yes.

8723. And has no relation to what might be disturbed by erosion?—No, the circumstances are taken alike on both days, the 14th and the 30th, as regards the quantity of water coming in and so on.

8724. (*Mr. Balfour Browne.*) The tidal oscillation which is shown by the floats of course makes it inevitable that there is sewage above Barking and Crossness?—Yes, I have no doubt of it at all.

8725. But do you know any method by which the amount of that sewage above Barking could be calculated?—I could not satisfy myself sufficiently, as to the *measurement*, to put it into figures, possibly somebody else might, and therefore I made that note; of course, I know the fact of its being there.

8726. Of course the sewage which you had been dealing with in your tables will not maintain its polluting character and nuisance-creating character all the way down the river?—That is a question which you had better ask the chemists. I have explained to the Commissioners that what I am dealing with is the volume discharged from the outfalls.

8727. So far as you, as an engineer, are concerned, have you anything to say as to what becomes of it?—I am quite certain that a great proportion of the solids sinks to the bottom, and I have something to say as to what becomes of it.

8728. That which sinks or goes down vertically to the bottom gives rise to the nuisance ultimately?—I think it gives rise to the greatest nuisance that ever occurs. I believe that some of the organic matter is deposited—mixing with the ordinary argillaceous matters held in suspension in the river; it goes down with them to form the banks, and then in very hot weather that matter rises and forms the patches of stinking matter which have been described.

8729. Then it is your idea that the banks in these reaches of the river are formed of that combination of argillaceous matter and sewage?—Yes.

8730. Now in the recent Mud Inquiry you plotted a number of cross sections of the river at an equal distance up and down above the Crossness outfall, I think?—Yes. The contention of the Metropolitan Board of Works in that inquiry with regard to the bank in Half-way Reach in front of the southern outfall, was that by dredging operations upon the north side of the river the sectional area had been abnormally increased, and that in consequence there the velocity was diminished, and that the banks were formed in that way. In order to satisfy myself as to whether that was the case or no, I plotted from the middle of Halfway Reach a number of cross sections for 12 miles—that would be six miles above, and six miles below, and then plotting the sectional areas as vertical ordinates, drawing a line from the highest to the lowest, I got what you may call a normal line, and I found that their contention appeared to be a true one—that there was a swelling in the river at that place.

8731. That is to say a swelling in the place where there had been dredging?—Yes, it was called an "aneurism" in the inquiry, there was an aneurism in the river at that spot and we had of course to own it. Perhaps I had better further explain that in getting out these areas I took the areas *without* the mud, because there were originally shoals upon the north side, and when those shoals were removed the contention was that the sectional area had been made too large. Plotting those areas *after* the shoals had been removed, but as if the ***mud had not been deposited***, it showed the aneurism.

8732. The object was to show what was the effect of dredging, and you must leave out the mud for that purpose?—Yes. Then I plotted similar areas with the mud *in* the river and I found that instead of there being an aneurism in the river at that point there was just the other thing, that is say, there was a constriction; the fact was, that the river, instead of being too large, was too small.

(*A drawing was handed in. See Appendix X.*)

8733. Will you just show upon the section both the aneurism that you plotted originally, and the constriction which you find now due to the mud (*the same were pointed out*)?—The longitudinal section was plotted in this way,—The areas of the cross-sections were taken at all the points shown by the vertical lines, and they were plotted from the one horizontal line at the top, so that the ordinates represent the sectional areas. Then the straight line is drawn from the one at six miles above to the one at six miles below, and that line shows that in Halfway Reach just in front of the northern outfall *before* the mud was deposited there was this enlargement. And my point is this, that as the Metropolitan Board of Works pleaded that, and pleaded it successfully, as the cause of the formation of the banks, I have the right to say now that the other thing has occurred, that the deposition of the mud has just caused a contrary effect, it has made the river too small for its work. In 1878 it was too small, and in 1882 it is too small, showing that there is some exceptional cause at work in that place to keep the river small. Either the stuff itself cannot be removed by the currents on account of its own inherent adhesiveness, or, if it is removed, it is immediately replaced. Then I want to add that this mud is caused by a deposition of the ordinary suspended matter of the river, plus the ordinary suspended matter from the sewers, and anything that points to such an accumulation of dirty mud is to the point in this case.

(*Mr. Bidder.*) Perhaps it would be convenient if I were to ask the Commission to consider (of course it is quite competent for you to do so if you think fit), how far you will embark again upon the same identical inquiry, which was the subject of this enormous amount of printed evidence and of the award of the arbitrators. Now what the witness is suggesting, is that the mud banks, which the arbitrators decided upon are the result of the outfalls, that is the very point upon which 1,200 or 1,500 pages of evidence were given in the Mud Inquiry.

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

(*Chairman.*) This point has been raised before, and I think I said, and all my brother Commissioners seemed to be assenting to it, that if it were necessary to go into the inquiry that was raised before those gentlemen, we should be obliged to do it.

(*Mr. Webster.*) The question then was the injury to the navigation, and the award was that there was no injury to the navigation. The question of the deposit of the mud and what it was (being a nuisance as it is in this case), in no way arose in that case.

(*Mr. Bidder.*) I beg my learned friend's pardon. The award of the arbitrators was distinctly upon the question, whether the mud from these banks did or did not come directly from the outfall.

(*Chairman, to Mr. Webster.*) You remind me almost exactly of my own words. I took the trouble previously to look into the award, and I saw what was the bearing of the award, and I saw that it bore simply upon the question of the navigation.

(*Mr. Webster.*) The award said, "Whilst, therefore, "the sewage of the metropolitan outfalls may have "contributed to the offence, the three banks cannot "be said, in the sense of the Act of 1870, to have "arisen from the flow of the sewage."

(*Sir John Coode.*) Moreover, the scope of our inquiry is not limited.

(*Mr. Webster.*) And you would not be bound by that if it were.

(*Sir John Coode.*) We are instructed to inquire whether any evil effects arise from the discharge of the sewage; our inquiry has no special reference to the navigation.

(*Mr. Bidder.*) I began my remarks by saying that obviously Royal Commissioners are not restricted in their inquiry by anything, even by the judgment of a superior court. It strikes me that this inquiry is likely to be a long one anyhow, and one may doubt the limits of human energy when applied even to a Royal Commission.

(*Chairman.*) I said, on a previous occasion, that so far from being a matter of estoppel, I should look upon this Commission, if it went over the same ground, as in the nature of a new trial.

(*Mr. Bidder.*) Of course you can go into it if you desire, but do not labour under the misapprehension which my learned friend is under that the arbitrators in that case confined themselves to finding that these mud banks were not a nuisance to the navigation, because they say:—"We expressly find that" "the "proportion contributed from this latter source is "small as compared with the total amount of sus- "pended matter in the whole volume of tidal water "which flows past the outfalls on every tide."

(*Mr. Webster.*) Then I beg my learned friend's pardon, but I distinctly say we are not going to try the navigation question over again.

(*Chairman.*) At the beginning of the 12th day of our proceedings you will find that the same point was raised.

(*Mr. Abernethy.*) According to my recollection the evidence in that case was confined strictly as to the effect of the banks on the navigation, and not as to their nature in a sanitary point of view.

(*Chairman.*) We think this matter is relevant to the inquiry and that the learned counsel had better proceed.

(*Mr. Bidder.*) Then I may take it that you consider it desirable to go into the whole question of the mud banks again.

(*Chairman.*) All that it is necessary to rule at present is that Mr. Balfour Browne is entitled to put the question he was about to put.

8734. (*Mr. Balfour Browne to the witness.*) Now, with regard to the question I have been asking you about, namely, the constriction, it was not, as I understand you, given in evidence before the arbitrators at all?—No, I had no opportunity of putting in this section. I was allowed to put in the cross sections but I did not put in this one, but I think it is quite pertinent to this inquiry and quite different from what was talked of in the Mud Inquiry.

8735. You have two plottings, one of 1878 and one of 1882—does the 1882 plotting show a considerable increase over that of 1878?—It shows a slight increase.

8736. I understand you to infer that the cause, whatever it is, of these accumulations is going on at present?—No doubt. This show there is some abnormal cause which allows the river to remain constricted at that point.

8737. The ordinary effect of the constriction of the river would be to increase the scour?—Yes, just the converse of the proposition that was put by the other side upon the mud question.

8738. But instead of there being a scour you infer that there is a constant accession of mud or a re-deposit of such an extent that it is replaced after a scour?—Yes.

8739. (*Sir John Coode.*) I see that these observations of 1878 and 1882 extend to about a mile and a quarter over that reach in the river which extends to Halfway House and there is no alteration elsewhere, have you limited your comparison to this mile and a quarter?—I have looked at the sectional areas and I found no increase or decrease of any importance; nothing that would alter this normal line materially; there would be an aneurism in the first case and a constriction in the other.

8740. You tell us that for the six miles above and below there is no material change?—There is no material change for the six miles above and below.

8741. When did you last test them?—By the last surveys from the Thames Conservancy people, within a year or two; what I have shown upon the bank is from the surveys of 1882.

8742. (*Mr. Abernethy.*) That is as far as the section is concerned?—Yes; the bank was about 1,500 yards long, I think, and I wanted to see what the change was upon the bank.

8743. (*Mr. Balfour Browne.*) Is there anything that you desire to add to the evidence which you have given in your examination-in-chief?—No.

Cross-examined by Mr. Bidder.

8744. Just a few preliminary questions upon that matter upon which you have been last asked. The question of whether there is an actual constriction at that point of the river a good deal depends upon whether your blue line, which is taken as what should be, is properly drawn or not?—I did not know how the thing would turn out; for my own information I obtained from the Conservancy Office their surveys, and took a distance of six miles up and six miles down, and plotted the sections, and then drew the line; that is the only way in which I could tell whether the river at this point had changed or not.

8745. I was asking you about the blue line. If, instead of taking the starting point of your blue line, as you have, you had taken, for instance, Margaretness Bank, 7 W upon your section and 11 E upon your section, and joined those two points together, would you not have had a very much larger difference?—It would have been an aneurism from end to end in that case. I took a length which I thought was a fair length, a length which I thought would give me a reliable basis to work upon.

8746. I am not suggesting that the points I have indicated are the proper points to take, but, in point of fact, the question of what is aneurism and what is constriction depends upon the question of where you select your points. I could draw a line which would put quite a good face upon it?—The way in which the points were selected was this; I took the middle of Half Way Reach, which represents the middle of the bank opposite the southern outfall, and I said I would take an equal length of section upon each side,

and I took the nearest section to that length that I could get from the surveys, but I could not tell whether it would be larger or smaller relatively.

8747. You chose to take six miles upon each side?—I thought 12 miles was a sufficient length of the river to give me the information I wanted, and I found that it proved your case, and I admitted it at once.

8748. Going upon that principle; taking, as you say, the middle of Half Way Reach; if, instead of taking six miles, you had taken five miles upon each side, you would have got a very different result, would you not?—It would have shown an aneurism without the mud and a constriction with the mud.

8749. If you had gone five miles upon each side, will you just show the Commissioners what your line would have been then?—I can see, without drawing a line, that there would have been an aneurism for you and a constriction for me.

8750. The blue line would have been pushed up a good deal?—I should have had to admit that you were right in that case, and I should have contended that you were wrong now. I knew nothing about it when I took these sections.

8751. I do not suggest for a minute that you selected particular points that would suit your purpose, for, as you say very fairly, you selected without any particular reason six miles upon each side?—Yes.

8752. And it is a matter of chance, you say, whether you happened to select five, six, or seven miles which showed a result one way or the other?—I think, if you were to take five miles upon each side, though the line would not be in the same place, the result would be the same.

8753. Just lay down upon the section before the Commissioners the blue line, taking five miles upon each side.

(*Chairman.*) We should be very glad to see how any alteration of the line would affect that bank if it exists.

(*Mr. Bidder.*) It just depends upon how you take the points of departure, whether it is an aneurism or constriction. (*The witness measured the distance upon the plan.*)

(*Witness.*) I have taken it a mile nearer upon each side, and it results in practically the same thing.

(*Sir John Coode to Mr. Bidder.*) If the tinted portion of the section is right, representing the ordinates, and the line is drawn there correctly, the changing of the line will not make any difference as regards the question of accumulation; it will as regards an average line; it has merely an effect just like raising or lowering the datum line of the section.

(*Mr. Bidder.*) But the witness's evidence is that, taking the contour of the river now as it is with the mud, there is, instead of an aneurism, a constriction, and by a constriction he means a sectional area less than the normal. Now, according as you shift the blue line, you shift the normal.

(*Witness.*) It is very little altered really.

(*Sir John Coode.*) At the same time it does not alter the fact of there being an accumulation there. As regards the constriction or aneurism, it does.

(*Mr. Bidder.*) Everybody knew there was an accumulation at that point on the last occasion, and everybody knows it now. You need not trouble your mind about whether there is an accumulation of mud there or not; there is, and we know it; and the question was as to the cause of the accumulation, as Mr. Mansergh has pointed out to-day. True, there is an accumulation, and we say that by dredging at that point of the river the sectional area was increased and turned into an aneurism, but Mr. Mansergh now says, "When I plot the river with the mud in, "instead of there being an aneurism, there is a "constriction."

(*Chairman.*) The witness says, "When I was "called as a witness on another inquiry, I had this "put before me, and I admitted, upon the facts "represented upon this plan, that there was an "aneurism; but, looking into the matter as I have "now done, and taking these data, and making the "necessary enquiry, I find that instead of there "being an aneurism there is a constriction."

(*Witness.*) That was not exactly so. I had done all this before, but it was not allowed to come out in the evidence for some reason or another.

8754. (*Mr. Webster.*) Did you make two sets of observations, one for the other inquiry and one for this?—The point I want to make is this, that there is a special cause keeping the bank there, and that that special cause is the sewage discharge; that with the sewage discharge organic matter is carried down with the other mud, and that that organic matter in hot weather becomes a nuisance.

8755. (*Mr. Bidder.*) When you say a special cause is keeping the mud there, you found that upon the fact, which you say your diagram shows, that there is a constriction at that point?—Yes.

8756. And that there is a constriction at that point you infer because the sectional area at that point is less than the normal area at that point?—Yes.

8757. Which normal sectional area is defined by the position of the blue line?—Yes.

8758. And it depends upon the position of the blue line whether the sectional area is greater or less than the normal?—Yes.

8759. It does come to that. The position of the blue line is at the root of the whole of the evidence?—Yes; but I have told the Commission how I obtained the blue line. I did it for my own information simply. When I found it told against me, I admitted it frankly, and now, when I find it tells in my favour, I am entitled to use it.

8760. You admitted upon the previous inquiry that undoubtedly the dredging operations of the Conservators had had a considerable effect in bringing the deposit to this spot?—Yes, I said so then, and I say so now.

8761. You have examined the other parts of the river above and below, and you found nothing of the kind?—No.

8762. You only point to a constriction below Crossness?—I was only trying to find out what was happening there.

8763. Did you look at the other parts?—I have looked generally at the sectional areas above and below.

8764. And you found no constriction?—There is, I should say, a constriction at Margaretness Bank and at Barking Bank; but about that Mr. More can tell you better than I can.

8765. But upon the last inquiry you did not confine yourself to that one bank, you gave evidence as to all three. How is it that you are now confining yourself to this point?—Because I am not bound to ramble all over the river. When I find a good point at Half Way Reach, I am entitled to make use of it. Mr. More can tell you what is going on at Margaretness and Barking.

8766. Your section shows several large white constrictions; are those the natural bed of the river?—Those are just worked out from the surveys of the Conservators as I found them.

8767. I see no evidence of any constriction at Erith Reach and Erith Rands. As far as I gather, in Erith Reach the sectional area is fully up to the normal?—It is just about the normal according to this test.

8768. Now I should like to understand, if I can, some of these tables of yours. That table M. 3*a*, and those in the same bundle, I suppose, are upon the same principle?—Yes.

8769. In the first table you have given the parts of chlorine per 100,000 derived from the chemist's analyses?—Yes.

8770. The "percentage of sea water (from chlorine)" and the "percentage of upland water, including sewage," as I understand, are derived in the way that Mr. Baldwin Latham explained?—Yes.

8771. I suppose you would admit that its accuracy depends upon the assumption which he took, and which I see you adopt at the head of the table, that

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

sewage contains 10 parts of chlorine and the sea water 1,961, and that, if those are wrong, the tables are wrong?—Yes; but in the parts below Crossness, to which I have directed the table, it would have very little effect indeed; so little, that it would not have any effect worth naming. I do not suppose it would have the effect of a tenth of a day upon the progress out of the river.

8772. Just take the fifth division above Crossness—this seems to be rather a fine matter—it is an inference upon an inference. You say the mean chlorine in that case is 4·7; then I see you say the percentage of sea water is 0·2?—Yes, that is taking into account the 1·7, the initial quantity.

8773. I will take that as an illustration. Sea water contains 1961 parts in the 100,000?—Yes.

8774. So that one per cent. of sea water would contain 19·61?—Yes.

8775. And one-fifth, or 0·2 per cent., would contain just under 4 grains, 3·9; is that right, 3·9 parts?—Yes.

8776. If I take that away from the 4·7, that leaves me 0·8 of a part?—Yes.

8777. How can that possibly be. I do not follow that, because that makes out that all the rest is only 0·8 parts in 100,000, whereas the river water contains more than that, and sewage still more?—Sea water is taken at 19·61, and, adopting Mr. Latham's formula, the result is 99·8 per cent. of upland water. Taking the 99·8 per cent. from the 100, you get the 0·2.

8778. You have only allowed the river water and sewage combined one-half the percentage of chlorine that there is in pure river water. There must be something fallacious in the whole business, because one-fifth of a part of sea-water has 3·9 grains, and that only leaves 0·8 of a part in 100,000 for the 99 parts remaining?—But where do you get the one-fifth of a part of sea-water?

8779. Percentage of sea-water 0·2; that is one-fifth of one per cent.?—That is 1–500th.

8780. That is 3·9 parts in 100,000 parts; that only leaves 0·8 parts for the rest; whereas, if it were pure river water alone, it ought to contain more than that?—You do not make it clear to me.

(*Mr. Lumley Smith.*) The 4·7 you are applying it to is the average figure, but it is not 4·7 at that particular point.

8781. (*Dr. Stevenson.*) In column 4 you have only taken the first place in decimals, have you? You have not gone to the second place in decimals?—It works out to 99·84 in salt water.

(*Mr. Webster.*) What Mr. Bidder has taken is 4·7 as the average figure, but if an average figure is taken, it must be something very different from 4·7.

(*Witness.*) The Chiswick sample was taken as the mean of the whole mass of five miles.

(*Chairman.*) The 0·2 does not mean the chlorine.

8782. (*Mr. Bidder.*) It means the percentage of sea-water derived by inference from the chlorine. (*To the witness.*) What I am wanting to do is to understand how this table is made up; how do you get at that?—I dealt with it by a formula similar to Mr. Latham's; A minus B divided by A minus C. A is the sea-water, 1961, and C is the chlorine in the sample found, 4·7.

8783. What does B represent?—The river water. A minus B divided by A minus C equals the percentage of land water. (*The witness exhibited his calculation.*) You get 99·8 as the amount of land water, and, taking that from the 100, you get 0·2.

8784. That is upon the assumption that the water is pure river at that point?—Yes.

8785. You assume there is no sewage there?—Yes; I do not take sewage into account till you get to Crossness.

8786. What do you do with the sewage at Richmond and Hampton?—All the analyses show that the water at Teddington contains 1·7.

8787. But Richmond is below Teddington?—I have only taken the chlorine as shown by the chemists.

(*Mr. Webster.*) It assumes it being all sea water except the 1·7.

8788. (*Mr. Abernethy.*) You have not dealt with the sewage question at all in this column?—Not there. I have taken the chlorine as it exists, whether it comes from the sewage or whether it comes from the sea.

8789. (*Mr. Bidder.*) Now, I want to make another thing clear; for instance, supposing, as I suggested to Mr. Baldwin Latham, that the sewage contains, not 10 parts of chlorine, but 20?—That would make a correction.

8790. That would reduce the sectional areas due to your sewage and water?—Yes.

8791. And accelerate your period of driving seaward?—No. I attach very little importance to it down to Crossness, and below Crossness it would make a little difference in diminishing the rate of progress.

8792. I see that from Crossness to Southend, upon that particular day you have taken, that 14th of September, the high-water figures would give you a period of 31 days to get to the sea. I suppose we may call Southend practically getting to sea?—Yes.

8793. The low-water figures would give you 33 days getting to sea?—Yes; but you must take the mean of that; you cannot compare them.

8794. That was taken at a time when the water coming over Teddington weir was exceptionally low?—Not exceptionally low.

(*Mr. Bidder.*) If you will look at Mr. Baldwin Latham's Report on page 49, where he tables the number of feet coming over the weir at Teddington, he gives the quantity on September the 14th as being only 83,327 cube feet a minute (I think I am more right than I thought I was), whereas he admitted to me that 150,000 was the average, so that it is about half the average.

8795. (*Mr. Webster.*) According to the Mud Inquiry the average water over Teddington Weir was found to be 133,000,000 cube feet in the 24 hours, and the minimum 57,000,000 cube feet?—According to this the average would be 110,000. Taking 3,676 square miles of drainage area, and taking the mean flow as 30 cube feet a minute, it is a little below the mean, but not very much.

8796. The other observation which you give, of the 30th of November, makes the rate of progress according to the high water figure of getting to Southend 14½ days, and according to the low water figure, 11 days?—Yes.

8797. How do you explain it, that whereas in the first case the low water figures give a longer period than the high water figures, in the second case they give a shorter period?—You must take the means. I do not profess that these tables of high and low water separately can be taken as representing the progress, you must take the means, it does seem a litle anomalous, but I think there is an explanation to it.

8798. The mean, taking the 30th of November figures, would be 13 days?—Yes.

8799. Therefore taking the results of these tables I might say the average maximum progress of the sewage derived from this cause would be something between 13 and 31 days?—No, the 30th of November is an exceptional time.

8800. One is something below the average, and the other is something above it, so I take it the mean would be between 13 and 31 days. If one is below the average and the other is above the average, the mean must be somewhere between them?—Yes, but, as I pointed out before, on neither of those occasions probably would there be a nuisance in the river, neither upon the 14th of September nor upon the 30th of November.

8801. But I want to get exactly at what the tables tell us?—They tell us the facts with regard to those days.

8802. Do the tables take into account the way in which the progress to sea would be accelerated by mixing with the sea water?—Oh yes, clearly.

8803. Just let me put a question to you which arises from the first table you put in. Your Table

M 1 shows roughly this, does it not, that the tidal section between Barking and Southend, is 18,000,000,000 cube feet at low water, and about double that at high water, is not that so?—Very nearly so.

8804. So that I may say that, on any given ebb of the water that was contained between Barking and Southend at high water, half of it has gone to sea at low water?—But then the same water comes back again.

8805. At any rate half of it has gone to sea at low water?—It has not gone to sea, it has gone a certain distance down the river.

8806. When I say "gone to sea" I mean gone past Southend?—But you must not understand that the whole of that dark blue strip has progressed out of the river, part of it has gone down.

8807. Between Barking and Southend at high-water there are about 36,000,000,000 cube feet of water, and at low-water only 18,000,000,000 cube feet?—Yes.

8808. And half of it has gone seaward of Southend?—Half of the whole *quantity*, but certainly not *that* dark blue water.

(*Mr. Abernethy.*) Not that particular tide water.

(*Prof. Williamson.*) That might all have gone and some other have taken its place.

8809. (*Mr. Bidder.*) If I take a pot with two quarts in it at 12 o'clock, and at 6 o'clock find there is only one quart in it, that shows that one quart must have gone somewhere, so that half the water between Barking and Southend has gone from between those points, it has gone somewhere?—Half that quantity has gone seaward, but it has gone from the extreme high-water line to the bottom of the river for a short length above Southend.

*Mr. J. Mansergh, M. Inst. C.E., F.G.S., F.M.S.*

7 Feb. 1883.

8810. Half of the whole of the water that is between Barking and Southend at high-water has gone to sea at low-water?—Yes.

8811. Without doubt?—Yes.

8812. And therefore, assuming that there may be 5 or 20 days sewage in the water between Barking and Southend, half of that has gone to sea?—But then it comes back to-morrow.

8813. It goes into the tides along the coast, does it not?—No, it goes 12 or 13 miles along the coast and comes back again.

8814. By what elective affinity can you show that, when that water has got to sea, it will, like salmon, come back to the river where it was bred?—But you will see that Southend is many miles short of the mouth of the river.

*Mr. Webster* stated that he feared Mr. Mansergh's engagements would not permit of his being present at the next week's sittings of the Commission, in which event he would be prepared to interpolate other evidence.

Adjourned to Tuesday next, at half past 12 o'clock.

---

# TWENTY-FIRST DAY.

## Tuesday, 13th February 1883.

PRESENT:

THE RIGHT HONOURABLE LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANCOIS DE CHAUMONT, ESQ., M.D., F.R.S
THOS. STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

MR. JAMES MANSERGH, Mem. Inst., C.E., called again.

(*Mr. Balfour Browne.*) Before my learned friend continues his cross-examination, I think it well to state that Mr. Mansergh has plotted on paper now what Sir John Coode asked for upon one occasion, and perhaps it is only fair that it should be put in before my learned friend, Mr. Bidder, resumes his cross-examination. One of the members of the Commission upon the last occasion asked Mr. Mansergh if he had taken the sections of the river above and below the outfall, as well as at the outfall, where he showed the aneurism. Mr. Mansergh has since that time taken the section both above and below, and will show the Commission the result of his survey. It was an aneurism, as the Commission will remember long ago, but now it has been turned into a constriction, according to Mr. Mansergh, by reason of the deposit of mud.

13 Feb. 1883.

*See Appendix X.*

8815. (*Mr. Balfour Browne to the Witness.*) You have also, I think, a line showing the high water up and down the river?—I have. These (*producing the Diagrams: See Appendix Y.*) are sections of the river upon the days of the tides which I named, plotted to the scale which the Commissioner asked for, namely, four miles to the inch horizontal, and eight feet to an inch vertical; those represent the synchronous lines of high-water, low water, mean flood, and mean ebb at Southend. These show the same thing at Barking (*pointing to the diagram*). The same was explained to the Commission.

*Further cross-examined by Mr. Bidder.*

8816. Just a question or two upon these diagrams that you put in this morning. I asked you last time, and you admitted to me that this blue line is what you may call to a certain extent an arbitrary line, that is to say, the starting points are selected arbitrarily, and that if the starting points had been selected differently the height would have been different?—No doubt. I explained how I selected it.

8817. No doubt you are aware, as an engineer, that that blue line is intended to represent what should be the normal river?—Taking the two ends as being normal points.

8818. Then you have drawn it as a straight line?—Yes.

8819. Are you aware that in theory, to make it perfectly correct it should not be a straight line?—I do not know how I should draw it differently.

8820. If the blue line is to represent a sectional

*Mr. J. Mansergh, M. Inst. C.E.*

18 Feb. 1883.

area proportionate to the water above it, it should be a curved line and not a straight line?—But it would be such a flat curve that you could not show it upon a thing of that sort.

8821. Surely?—No, you could not.

8822. I have drawn your attention to it, and that is enough. Now you said upon the last occasion that, upon the former inquiry, when the question of whether the banks were caused by the sewers or not was the subject of inquiry, you were not allowed to put the section in. Now I have been looking at the evidence and I cannot find that; therefore I must ask you, was there any objection taken upon the part of the Metropolitan Board of Works or the arbitrators to your putting in any section you liked?—Not at all. I did not say that the objection proceeded either from the Metropolitan Board of Works or the arbitrators.

8823. I am sure you would not mis-state a thing, but it appears from the notes as if the Metropolitan Board of Works or the arbitrator, had objected to it?—No, it does not read upon the notes like anything of the kind.

8824. You simply mean there, that your counsel did not think it expedient to bring it forward?—Yes, probably that was so; possibly I was not pertinacious enough about it.

8825. Now, I leave that, and I have one or two questions more to ask you with regard to the subject upon which I broke off when we were here last. This table of yours, M 3a., from which mainly your deductions are made, purports to show the condition of the river at high water and at low water upon two different days, the first being the 14th September and the second the 30th of November, and it purports to show also, first, the cubic content of the river in each division; I see that you have divided it into five mile lengths?—I have divided it into five mile lengths, except the one at Teddington.

8826. Then it purports to show the percentage of sea water, quantity of sea water, percentage of upland water, including sewage, and the number of day the sewage takes to travel down to different points?—Yes.

8827. I want to make it quite certain, and to understand the principles upon which these tables have been founded. First, as regards the cubic content of the river in each division, that of course is a mere question of measurement?—That is the measurement from the cross section.

8828. Now, as regards the rest, as I understand, the actual facts from which you have constructed this table, are these. First, that at certain points in the river on the occasion referred to, the chemists took samples of the water and ascertained how many parts of chlorine there were in 100,000 parts?—Yes.

8829. And from those observations you deduced the proportion of sea water in that part of the river?—Yes.

8830. I am anxious that his Lordship should follow this, because it is at the root of the whole table. (*To the witness.*) At the head of your table you say that pure sea water, you assume, contains 1961 parts of chlorine in the 100,000 parts?—Yes.

8831. The sewage and upland water in both cases contain compared with that, an infinitesimal quantity?—Yes, upland water 1·7 and sewage 10.

8832. So that you may put it that supposing, as in this table, you find in the first division below Crossness that there are actually 1031 parts of chloirne in 100,000 parts you ask yourself the question, how many parts of sea water must there be, and how many parts of fresh water, without any chorine to make up that mixture?—Yes.

8833. That is a mere question of mixture?—Yes.

8834. From that you deduce the column No. 4, which is the percentage of sea water?—Yes.

8835. And of course the complement of that, to make up the 100 in column 6 which is the percentage of upland water and sewage?—Yes.

8836. Now in order to make that estimate of how much of that column 6, percentage is upland water, and how much is sewage, you make an assumption that the upland water and sewage are in the proportion that the quantity of water, that you gauged coming over Teddingtom Weir and other tributaries during that day bears to the quantity of sewage that you know the Metropolitan Board of Works have sent out?—Yes.

8837. So that I have accurately stated the basis of the table?—Yes.

8838. Will you turn now, if you please, to the 30th of November, the same principle applies to all these tables?—Yes.

8839. Taking the 30th of November, at high water, the lowest division, the sixth division, below Crossness, you there deduce in that way, that 86 per cent of the water in that division at high water is sea water?—Yes.

8840. And 14 per cent. the other water?—Yes, 13·70 per cent.

8841. And you have got that, assuming that the sea water contains 1961 parts of chlorine?—Yes.

8842. Of course that sea water comes from below Southend?—Yes.

8843. Do not your own analysis there, and the chemists analysis upon which you based it, show that upon that day the sea water below Southend did not contain 1961 parts of chlorine, but only contained 1785 parts of chlorine? I draw your attention to the table which Mr. Baldwin Latham put in to page 4 of the analysis of Professor Way. Now in the last pair of columns there is given the chlorine upon this very day, and I may in point of fact say that those are the very analyses upon which your table is based?—The analysis my table is based upon is this (*producing a paper*).

8844. Is that the same as Professor Way's, to which I am drawing your attention?—Yes.

8845. Now look at the 30th day of November, and you will see that Professor Way shows that at high water at Southend, the water contained 1785 parts, and at low water, 1522 parts, and that even at Margate, which is 30 miles away to sea, at high water it contained 1770, and at low water 1735; at Margate, as we know, the estuary is 30 miles broad, does not it follow from that table that the water which came up from the sea to Southend and filled the river at high water was not water containing 1961 parts, but water containing 1774 parts?—Yes, because upon that day, and for some time before that day, a large quantity of fresh water had gone down the river.

8846. But your table was based upon the assumption that water came in from the sea as, if I may use the phrase, "standardly" pure sea water, whereas the analysis show that out in the estuary 30 miles in width the water was of a much lower standard?—If that is the assumption——

(*Mr. Webster.*) But it is not the fact (as we have given evidence) that the water at Margate is pure sea water, it is in fact very much diluted, we do not admit that the water at Margate is pure sea water, or anything like it.

(*Mr Bidder.*) I was drawing the witness's attention to this fact, that the water of the estuary below Southend down to Margate, was not water containing 1961 parts of chlorine but was water containing something over 1700, say 1750, taking the mean at Margate.

(*Witness.*) All it shows to me is this, that a large quantity of land water has come down the river, and even as far as Margate, is diluting the sea water.

8847. Will you just turn your eyes to the map. Margate, as we know, is at the very point of the North Foreland, is it not, or close to it?—Yes.

8848. And the estuary there is about 30 miles broad, as nearly as I can recollect?—Yes.

8849. Whatever may be the cause you may say the upland water or anything else. I do not know what the cause is, you do not suggest to the Commission that the sea at Margate is composed of fresh water?—I do indeed; I say that the fresh water which comes down the Thames had that effect upon the sea

water at Margate upon that day. If you take Southend you will see——

8850. I would rather keep to Margate, if you do not mind. Therefore I am not wrong in saying that if your assumption is right the figure represents that about 12 per cent. of the sea at Margate is fresh water?—I dare say it is; it would work out to that.

8851. But am I not right in suggesting that that would be more fresh water than the river would produce in a year?—Yes, but you must not take it all over the river; that might be due to the currents along the shore.

(*Chairman.*) If I understand it rightly, it is three times the percentage of fresh water at Southend.

(*Mr. Bidder.*) It is three times what it was at Southend on the 14th September.

(*Chairman.*) Upon the Table M. 3a, you state the percentage of upland water and sewage as 4·30 at Southend, but it can hardly have been more salt there than it was at Margate.

(*Mr. Webster.*) Is your lordship comparing the particulars of the same day?

(*Witness.*) We have no Margate samples upon the 14th and 22nd of September, but if you compare the great difference there is from Southend upon the same day, you will find my statement borne out.

8852. (*Mr. Bidder.*) I do not know where you got your figure of 1961, as representing pure sea water from?—That is a chemist's business, I got it from the chemists.

8853. You may be aware as a matter of fact that it is a matter of general observation that the amount of salt in the English Channel, is considerably less than the standard of pure sea water?—I do not know that. I had that from the chemists.

8854. Now comparing the 30th of November, high water with low, I put it to you upon the last occasion and you substantially admitted it. I am right in saying, am I not, that substantially the content of the river at high water between Southend and Teddington is twice what it is at low water?—That is so.

8855. And half the water in the river therefore it follows at any particular high water goes out seaward of Southend during the ensuing ebb?—Yes.

8856. And is replaced at the next flood by substantially an equal quantity of salt water coming from the estuary?—Yes, but the 18,000,000,000 or the 19,000,000,000 you are talking of represent only about eight or nine miles at the low end. If you will take one of the blue sections, say a spring tide section, although the dark blue, which represents the quantity coming in during the flood tides amounts to 18 millions in the length from Barking to Southend, that whole strip does not go out because that quantity is contained in the eight miles at the bottom end immediately above Southend.

8857. Have I ever said that it goes out in that ridiculous way; all I put to you, and what I want to get broadly clear is, that half the quantity has gone. I do not say that it comes out n that ridiculous strip?—You may say that piece (*pointing to the plan*) has gone out of the river. The water from the dark blue follows down to fill the low water section below.

8858. I will still deal with your table; for instance, upon the 14th of September, taking the high water figures, the whole of the sixth division below Crossness with its 14,430,000,000 has gone to sea?—The whole of that quantity has gone to sea, and some of the next division.

8859. About two-thirds of the next division?—Yes, about three miles of the next division.

8860. And with it has gone to sea the 93,000,000 of sewage that was in it, and two-thirds of the 136,000,000 that was in the next division?—Yes, out of that low bit; but the water in the dark blue, the high water part, simply goes into the low water section.

8861. At the ensuing high water, a similar quantity of water comes up from below Southend?—Yes, from below Southend.

8862. And you will not suggest to the Commission that it is the identical water that went out?—No, of course I cannot suggest that it is the identical water that went out; so long as it is within the river, it has oscillated up and down to a certain extent, but that it is the identical water, drop for drop, no one, of course, could say.

8863. In point of fact then, it amounts to this, does it not, that in a tide about seven days' sewage is swept out to sea, according to your figures, if your table is right.

(*Chairman.*) Every tide?

8964. (*Mr. Bidder.*) I have not added what is coming next; this is if Mr. Mansergh's table is correct—I am going to say that it is entirely wrong (*to the witness.*) If your table is correct, several days' sewage is swept to sea every tide; you may say that some of it comes back, if you like, by the next tide?—26,000,000 I take as the sewage.

8865. If you look at your table, the whole of the last section which contains 93,000,000 of sewage has gone to sea, and two-thirds of the next section, which is about 90,000,000 of sewage, that is 183,000,000, which is equal to seven days' supply?—Yes, but it comes back again.

8866. You may say that if you like, I am only establishing the deduction from your tables, if your tables are correct that seven days' sewage is swept into the estuary every tide?—Swept below Southend.

8867. Do you suggest that the whole of that comes back every tide?—Some proportion of it.

8868. Having regard to the fact that it is mixed up by the tides and currents and the eddies and the estuaries, what proportion would you say comes back, roughly speaking?—You can only deal with it by taking, as we have taken it, the chlorine and estimating the quantity of sea water in it.

8869. Your chlorine test, assuming it is rightly applied, only shows that a certain percentage of water in that part of the river is not sea water?—It shows that it is not sea water.

8870. It does not show that it is water that comes down the Thames, or that it is water that comes down the sewers?—It must come either one way or the other.

8871. I will show you another place that it might have come from, it might have come from the Medway, might it not?—We take the end of the river as being at Southend, so as to avoid any complication with the Medway.

8872. The Medway pours its water into the estuary of the river a little below that point, does it not?—Yes.

8873. And that water comes back with the tide?—Yes; we can only get at it by the chlorine.

8874. Therefore a proportion, I will not undertake to say what proportion, of this water which is brought in by the tide is Medway water, and not Thames river water at all?—It is so.

8875. And your inference that because there is so much fresh water, there is therefore that proportion of sewage in it, would fall to the ground?—Yes; but in dealing with this lower division; it is a matter of very little importance, we know that at Southend very little injury is done by the sewage, but taking it at Barking and Crossness, where you are not complicated with the Medway water, you cannot contend that the Medway water comes up that 30 miles; I do not say that any nuisance arises at Southend.

8876. But the same principle applies all over your table?—But you cannot get water from the Medway up as far as Crossness in a tide.

8877. Why not?—Because the tidal oscillation would be 30 miles.

8878. The water below Southend is weaker than sea water, because it is mixed with fresh water?—Yes.

8879. And that mixture arises partly from the water of the Medway?—Yes.

8880. The water which comes from below Southend is the only water from which you could account for any excess of chlorine at Westminster?—Yes.

*Mr. J. Mansergh, M. Inst. C.E.*

13 Feb. 1883.

8881. Therefore, you may reasonably infer that where you find in the channel of the Thames any excess of chlorine, you must have some of the Medway water?—Yes, no doubt. It would be of import just at the mouth of the Medway, and in that direction, but higher up it is of very little import.

8882. Running into the Thames, besides the Medway, there is the Blackwater.

(*Chairman.*) And the Colne.

(*Mr. Balfour Browne.*) All those are included in the table.

8883. (*Mr. Bidder.*) I think the Blackwater is not included in the table, because if you look at column 8, showing the quantity of upland water, you will see that it never increases below Crossness?—All I say is, that we have taken all the water coming into the river above Southend.

8884. But your own chemists' analysis have established that this dilution extends to Margate; now do you happen to know, as regards the Medway, what is the average amount of drainage?—No, I do not know anything about it.

8885. Your table shows, and I mention it, because Mr. Balfour Browne interpolated a remark about these being all included, that you have included nothing that comes into the Thames below Erith?—I told you that the tributaries were so small that I had put them all in at the top of the second division below Crossness.

(*Chairman.*) There are considerable floods in the Medway above Maidstone in very bad weather such as this, but in ordinary weather very little water comes down.

(*Witness, to Mr. Bidder.*) You will see that I put in all the tributaries at the head of the second division; it is all to your good as far as progress is concerned.

8886. (*Mr. Bidder.*) One thing catches my eye on looking at the table; if you look at the 10th column, there is another curious result in the table, that in the third division below Crossness you seem to have actually less sewage than in the one below that?—Yes, that is deduced from the figures.

8887. Do you believe that?—Yes, I do.

8888. Less than the one above it, and less than the one below it?—Yes; I am only basing it upon the chlorine and the contents.

8889. Do you believe it is true, as a matter of fact?—I believe the contents are correct.

8890. How do you account for it?—I do not attempt to account for it at all. I have taken 1502 as the chlorine at Gravesend. I know the contents are right, and all the other figures are simply worked out from them. It seems to be an anomaly, but there it is, I cannot account for it as a fact.

8891. Of course your table does not pretend to take any account of the extent to which the sewage has been destroyed by decomposition?—No.

8892. It is a table that assumes that if a gallon of sewage is put into the river at Barking or Crossness, it will remain a gallon of sewage until the end of time?—In quantity. I simply stated when I described the table that it represented the quantity which came down through the sewers.

8893. A gallon of sewage put into the river at Barking or Crossness, according to the figures in your table, is a gallon of sewage, though it may have been down to the estuary, and may have, in fact, returned after many months?—That is what it means.

8894. Your own experience tells you, does it not, that in practice, sewage put into a large volume of running water is very rapidly burnt up?—I think I must leave the chemists to deal with that question.

8895. I have had the pleasure of examining you very frequently upon sanitary matters, and water questions, and I ask you to give the Committee the benefit of your experience and opinion. Is it not the result of your experience, that sewage put into running water is very rapidly annihilated and destroyed by chemical decomposition?—I think it is destroyed to some extent, but I do not know how far.

8896. Does not your experience lead you to believe that that applies to a very great extent?—When men like Dr. Frankland and Dr. Tidy, and other gentlemen of their eminence disagree, I had rather leave it to them; it is a question for the chemists.

8897. But you have not been afraid to give your opinion upon other occasions, do not let any new accession of modesty prevent you from doing it upon this occasion?—I would much prefer leaving it to the chemists.

8898. Is it not your belief that running water, to a great extent, purifies sewage and destroys it?—I think it does to some extent; but I think also that a good deal of the solid matter is deposited in the bed of the river.

8899. Of the matter in suspension?—Yes.

8900. Now I must ask you upon that, this question as that is coming back to the mud banks. As you referred in your evidence upon the last occasion, and as you pointedly refer to the mud banks now, let me ask you, do you agree with me as to one paragraph on page 26 of the report of the arbitrators upon that inquiry "That each of the three banks," one of them is the very bank you have been drawing attention to this morning, "has arisen from the dredging operations in Barking and Halfway Reaches carried on by the Conservators of the Thames, or sanctioned by them; such dredging operations having removed material, and having increased the sectional area, of the river, and altered the direction of the flow of the currents and tide, so as to produce a diminished velocity in those parts of the Reaches where the banks are situated, thereby causing a deposition of matter suspended in the river and the formation of the three banks"?—Yes.

8901. Do you agree with that?—I do; but I also want to emphasize the other point; that now there is no increase of the sectional area, there is just the other thing, there is a diminution of the sectional area, and therefore an increase of the velocity.

8902. Let me put this to you, when you say there is a diminution of the sectional area, is not the sectional area at that point now greater than it was before the Conservators began their dredging operations, still making allowance for all the mud bank which is found there?—I do not think I can give you the figures now, but I should say not, certainly.

8903. Do not say so unless you have ground for it, for I have very strong ground for holding the opposite opinion?—I believe the 1861 area is here somewhere.

8904. You have given us a certain amount of sectional areas of the river upon the paper M 2; but you have cross sections of the river all the way down, have you not?—I had 134 plotted.

8905. Have you objection to producing them all?—I do not think so; my cross sections, as I explained, are between something above high water and something below low water. The sectional areas below low water, that is below 7·50 under ordnance datum, are from Mr. More, excepting where the mean area sections are given, and those I have calculated.

8906. There seems to be some errors in this table of yours?—Which is that.

8907. Table M 2; they may be serious or they may not, but I will show you. Opposite Deptford you will see the low water area upon the 14th of September is 12,927 square feet, then referring to the 30th of November it is 12,900 square feet, which is rather less; but, if you look at the point to which the tides ascend in a few days, it was lower water upon the 14th of September than it was upon the 30th of November, so that with a larger depth of water you have a less sectional area?—But it was a deal higher at Teddington.

8908. Never mind Teddington, let Teddington take care of itself?—You must draw a line between the two.

8909. Does not table M 2 purport to give the sectional area of the river at high water and low water at particular places?—Yes.

8910. Then I draw your attention to this, that at Deptford you represent the sectional area, to be

greater upon the 14th of September than it was upon the 30th of November, although the water itself had sunk to a lower level?—Where do you say it was lower.

8911. O.D. minus 7·50, is not that the tide?—Yes, that is lower.

8912. The next is O.D. minus 7·40?—But that is at the 74th section, that is miles below Deptford, and you must get the mean level by drawing a line between the two.

8913. You will correct me if I am wrong, but I am told that these figures must have been taken from the tide gauge at Deptford?—I am positive about all these areas. I have checked them and cross checked them in every possible way, and I can satisfy Mr. Law that that is right.

8914. You stated that you agreed with the finding of the arbitrators with regard to the banks, but you said that the suspended matter came from the sewers; now I will ask you if you agree with the next paragraph that "the water in the tidal portion of the "Thames contains a considerable amount of suspended "matter derived partly from the basin of the Thames "and its tributaries, partly from the washing away of "the foreshores of the tidal estuary, where unpro-"tected, partly from material brought up from the "mouth of the river by the flood tide, partly from "sand and mud stirred up in the course of dredging "operations, partly from denudation of the river bed, "partly from sewers in districts outside the Metro-"politan area, and partly from the sewers of the "Metropolitan Board. The proportion contributed "from this latter source is small as compared with "the total amount of suspended matter in the whole "volume of tidal water which flows past the outfalls "on every tide"?—That may be so.

8915. Then we go on a step further—"That the "three banks are composed of matter which has been "held in suspension in the water, and had been "derived from the several sources above mentioned. "Whilst, therefore, the sewage from the Metropolitan "outfalls may have contributed to their contents the "three banks cannot be said, in the sense of the Act "of 1870, to have arisen from the flow of sewage at "the outfalls"?—I do not object to this judgment, but still I say, as the arbitrators say here, that a part of the banks is formed from the discharge of the sewers; that is all I want to say now.

8916. Now we will leave the mere words and follow the substantial reasoning. The banks formed at that place because the velocity of the water had been diminished?—Yes.

8917. And the comparative stagnation or reduction of the velocity caused the matter in supension in the water to fall to the bottom?—Yes.

8918. Whatever matter happened to be in suspension at the time, provided it was not too light, would go to the bottom and help to form the bank?—Yes.

8919. And of that matter, which in point of fact is matter in suspension in a gallon of Thames water, a very small proportion indeed has anything to do with the sewers of the Metropolitan Board of Works?—A small proportion, yes.

8920. Therefore, as regards any bank which is formed in that way, a very small proportion at the best can be traced to the sewers as its origin?—Yes; but that is the portion which creates the nuisance in hot weather.

8921. Now you are riding your other horse?—I must ride my other horse.

8922. Of course you may say that a grain of prussic acid may be much more serious than an ounce of salts but we are upon the question of whether a bank is composed of sewage or not?—But I say that the river is too small—you made it out too large before, and I say fairly made it out too large; but now it is too small, and that shows that there is some abnormal cause at work. To state it more fully, the contention of the Metropolitan Board of Works originally was that on account of dredging operations in the Dagenham shoals, the river had been made too large opposite the southern outfall, consequently the velocity was reduced, and any suspended matter in the river was deposited. Now, I say, since the discharge has gone on for 15 or 20 years, the river has been actually made too small at that place, therefore the velocity has increased, and yet it is not sufficient of itself to remove the banks which are formed, showing that there is some abnormal cause at work—either that the material discharged is of an unusually adhesive character, or that it is immediately replaced when the bed has been scoured.

8923. But when you say that the river is too small, I venture to challenge you as to whether the sectional area of the river is not now larger, with all the mud in it, than it was when the Commissioners began dredging?—My opinion is, though I have not the sections here, that you will find the river is smaller.

8924. Your own Table M 2, shows that instead of there being a constriction at that point, there is, on the contrary, a very great enlargement. Look at high water upon the 14th of September: the first that comes, or I will take, as being better, the sectional areas at mean tide level. At Barking you give the sectional area at just a little under 44,000 feet, but when you come to Crossness, which is only a mile and a half below it, you show the sectional area to be increased to 50,200?—Yes, that may be the mean side sectional area, but I give you the low water areas plotted upon that diagram, which will show that upon the whole there is a constriction.

8925. Now going back for a moment to Table M 3a, the quantities of sewage which are shown in the table represent by sewage the general liquid which comes out of the sewers of the Metropolitan Board of Works?—Yes, that is what I have said.

8926. But of that, of course, only a very small proportion indeed would be what would be called sewage proper?—We call sewage proper everything that has gone through the house, the fouled water supply.

8927. But it may be water that has gone from the roofs and the gutters?—Yes, it would include that.

8928. But the mere excreta would be a very small proportion of the whole?—I am not going down to excreta. I am speaking of the 30 gallons a head upon the north side.

8929. But the foul element of the sewage is a very minute percentage, something like half per cent, is it not?—I do not know about the quantities; the quantity I am talking about is the fouled water supply, what we know technically as sewage.

*Re-examined by Mr. Webster.*

8930. I will take first the question which has been put to you last of all; is it the fact that the limit of one-half per cent of excreta would be the sole polluting element in the sewage?—Certainly not.

8931. There would be kitchen water, and all kinds of things that would increase the polluting element?—Yes.

8932. I understand you to say, whatever the result, that you have dealt with the quantity which is supposed to be poured out at Barking and Crossness?—Yes, that is so.

8933. It is clear from your own sections and plans, that opposite Southend, and for two or three miles above, the estuary expands considerably?—Yes.

8934. And of course the cross section increases considerably?—Yes, it does.

8935. In order to ascertain what is the real result of washing backwards and forwards in the River Thames itself, do you think that the lower reaches are as important as, we will say, the 15 miles below Crossness?—No, certainly not.

(*Chairman*). Is the witness an expert upon the point?

(*Mr. Webster.*) I think so, my Lord. I am not

*Mr. J. Mansergh, M. Inst. C.E.*

13 Feb. 1883.

suggesting that he can tell your Lordship exactly; but my learned friend, Mr. Bidder, has put to him in cross-examination that in the lower section the whole of it would be washed out, and I merely wish to get his opinion that the upper reaches are more important than the reaches nearer the sea.

(*Chairman.*) I thought my brother Commissioners were as capable of judging the value of the different reaches of the Thames as Mr. Mansergh.

(*Mr Webster.*) I quite agree with that; but sometimes counsel does not want to take the whole responsibility of leaving a matter without questions being asked upon it.

8936. (*To the witness.*) Two matters were pointed out the other day, to which I should now refer. When you worked out the percentage of chlorine in sewage, it was suggested that your percentage was wrong?—Yes, it was.

8937. I believe you have again checked your formula?—I have.

8938. Will you state now how you carried out the calculation?—Dealing, as I was, broadly with the question, interpolating mean chlorine for a large mass of water (five miles in length of the river), it would have been undue refinement to go to several places of decimals with the percentages. By leaving the figures as in the table, there appears to be an error, but this is not so if they are carried further, thus,—

$$\frac{1961-4\cdot7}{1961-1\cdot7}=\frac{1956\cdot3}{1959\cdot3}=\cdot9984688,$$

which is the proportion of upland water. Multiplying this by 1·7, the chlorine in upland waters, we get $\cdot9984688\times1\cdot7=1\cdot6973969$. Then deducting the ·9984688 from 1· we get ·0015312, which multiplied by 1961, the chlorine in sea water, gives 3·0026832, and this added to the 1·6973969 makes a total of 4·7000801, which is the exact figure given in the 1st column of the table.

8939. In the column below Crossness it made no difference at all?—No difference at all; and it would have absolutely checked if it had been carried sufficiently far.

8940. Is it the fact, as far as you can judge, that there is a difference between the sea water at Margate as compared with the sea water at Southend. I will read the figures off to you from the tables; it is 1785 at Southend and 1770 for Margate upon the 30th of November at high water, and at low water at Southend it is 1522 against 1735 at Margate?—Yes.

8941. Therefore, upon the only day that we can compare, there is at high water a little more chlorine at Southend, and at low water considerably less than there is at Margate?—Yes.

(*Chairman.*) You think it may be more salt at Southend than at Margate, or as salt, at all events.

(*Mr. Webster.*) As salt.

(*Chairman.*) I do not see the impossibility of it, because the tide in the channel fills in from the north, and it may be that the rivers that flow into the German Ocean are not so considerable in proportion to the volume of water they meet there.

(*Mr. Webster.*) We should not be surprised at any result; but what I wish to point out as far as your Lordship has it now before you, is that upon the day that we compare it, the water is as near as possible substantially the same; it is 1,785 as against 1,770, a difference of 15 parts only at high water, and at low water it is 1,522 as against 1,735, or a difference of just over 200 parts, so that there is not the marked difference which your Lordship pointed out, taking another day's table, when you put it at four times the proportion.

8942. (*To the witness.*) You have said over and over again that the quantities of chlorine you have taken from the chemist without altering them at all, and you have made your deductions from them, assuming them to be facts?—Yes.

8943. I think this is clear. My learned friend, Mr. Bidder, suggested to you that you had assumed that a gallon of sewage remains a gallon of sewage for the purpose of all the calculations. Is it the fact that any gallon of water in the river below the outfall may be made up of water which has gone out to sea, and of water that has come back again?—Yes.

8944. And may be a mixture of any number of gallons which have previously come from the river itself?—Yes.

*Mr. Bidder* objected.

(*Mr. Webster.*) We are working back from a given state of chlorine, and the deductions may be wrong, but we do not assume any quantity of sewage except what is shown by the deductions from the chlorine.

8945. (*To the witness.*) Now you have said fairly enough, as I think, that the float experiments cannot be relied upon for actual calculation, but only show the range of the floating up and down of a certain part of the water?—That is so.

8946. Do you think, given that range of the tide, that any great volume of the Medway water, as fresh water, can get up the river?—It cannot get very far up the river.

8947. About 12 miles, as we know, is the extreme range of any tide?—Yes.

8948. Therefore it must be very largely diluted at any point above Southend?—Yes, certainly.

8949. I ought to say that it is not the fact that the Blackwater goes into the estuary, that is the River Crouch at Maldon, and not the Blackwater. (*To the witness.*) My learned friend, Mr. Bidder, puts it to you, that it is possible (and you have not yet checked his figures) that where that bank is the river may be in fact larger than it was before the dredging operations of the Thames Conservancy took place?—Yes.

8950. At present you have not your figures to check that?—I have figures with regard to the year 1861, but I have not them here.

8951. Taking your section, showing what it does now, if they are facts, and comparing what the state of things was at the time of the Sewage Inquiry with what it is now, do you or do you not consider that there is a constriction in the river there?—I do.

8952. Having regard to the section of the river below it and the section above it?—Yes.

8953. And if the reasoning as to the increase of velocity is sound, that ought to induce a less deposit instead of a greater deposit?—Certainly; the increased velocity ought to remove the bank.

8954. (*Chairman.*) But there is a diminished velocity above the constriction?—No doubt, relatively, in the constricted section the velocity ought to be increased; if it is increased, it ought to scour away the banks, but it does not scour away the banks.

8955. (*Mr. Webster.*) Or, if it does, it re-deposits almost immediately?—It does.

8956. (*Chairman.*) If you refer to table M 3a, upon the lowest line but one, I see 6,000,000,000 cubic feet of water, with a percentage of 12½ of upland water?—The 6,372,982,770 is the quantity of sea water in that division.

8957. And there is a percentage of 12·50 of upland water?—Yes, 910,000,000.

8958. In the division below that, there are 13,800,000,000, with a percentage of 4·30, and only 620,000,000 of upland water—what has become of the rest of the upland water?—This table really represents the quantity of upland water out of the whole volume of water in the river at that place.

8959. But I want to know what has become of it, if the total volume of water is double, that is to say, if the content of the river is double, one would suppose it would have at least half the percentage of upland water that the single quantity had?—Yes, but these percentages are of the two divisions of the river at the same time; the 5th division contains only half the total quantity.

(*Chairman.*) Then there is nothing in my question.

(*Mr. Bidder.*) I venture to think that there is something in your Lorship's question, because what is to-day the water in the 6th division would be in two or three days the water in the 5th division.

(*Chairman.*) I understood you to say that the coming in of the salt water had driven back the fresh water.

(*Witness.*) It merely follows from the two facts that we have to go on, the content of the section and the chlorine found.

8960. (*Mr. Balfour Browne.*) Has the mixing any bearing upon it?—The mixing is shown by the chlorine.

*Mr. J. Mansergh, M. Inst. C.E.*

13 Feb. 1883.

The witness withdrew.

Mr. Charles James More, Mem. Inst. C.E., examined.

*Mr. C. J. More, M. Inst. C.E.*

8961. (*Mr. Lumley Smith.*) I believe you are engineer to the Conservators of the River Thames?—I am.

8962. You have been so, and have been constantly upon the river, have you not, between London and Gravesend for the last 13 years?—I have, as engineer and assistant engineer.

8963. Do you go over other parts of the river?—I go in all parts of the river.

8964. Have you personally surveyed the river at the lower part below London Bridge?—I have as far as the lower end of Long Reach.

8965. Are you acquainted with the nature of the bed throughout the whole of that district?—I am at one period or another, and quite recently with the part which is near the outfall.

8966. To begin with the terminus *ad quem*, going upwards from Long Reach, how far does your personal knowledge of the bed extend?—Up to the pool, close to London Bridge.

8967. In various places you find accumulations of mud, do you not?—Yes.

8968. Is that uniformly deposited over the bed, or is it found in places?—It is found in parts almost entirely across the bed; at other parts it is simply in bights. I have before me three plans which show exactly the present condition of the bed of the river, which I wish to place before the Commission; they show the deposit of mud, gravel, clay, and peat.

(*The same were handed in. See Appendices* Z 1, 2, 3).

8969. (*Chairman.*) When you speak of the mud, did you go down merely to the surface?—The mud is of all depths, it is from 6 or 7 inches to 8 or 10 feet depth. I merely show the surface of it.

8970. Would you say that the mud was a part of the natural bed of the river, or something that has been brought there from time to time?—It is evident that that has been brought there, because the natural bed of the river was gravel originally; how it was brought there, is the question.

8971. (*Mr. Lumley Smith.*) Let me take you through the different reaches; first of all, will you allow me to direct you to Bugsby's Reach; in Bugsby's Reach what do you find?—In Bugsby's Reach there is not much deposit of mud until you get down to the lower end of it, except upon the foreshore, that is between high and low-water mark.

8972. Is that on both sides?—That is on both sides, and that would vary very much according to the season and the amount of rainfall; in the higher reaches of the river especially it varies with the rainfall.

8973. Now, we will take Woolwich Reach?—Woolwich Reach is a very muddy reach indeed; there is a very large deposit of mud in Woolwich Reach, extending almost across the river.

8974. Is that subject to variation?—Yes, the depth of that would vary a foot or two feet at times.

8975. Does that vary according to the season of the year or year by year?—Year by year, the surveys show a difference in the depth of water from one to two feet.

8976. Now, Galleon's Reach, what do you find there?—Galleon's Reach, upon the Essex side, is very muddy indeed; all along the bight it is. Up near the Beckton Gas Works there is a great depth of mud.

8977. And upon that reach is situated the Barking outfall, is it not?—At the lower end of that reach.

8978. Does the mud extend to there?—Yes, the mud extends as far as Barking Creek, all round the lower end of the bight.

8979. Is it of any depth?—Yes, it is 6 or 8 feet deep.

8980. Now the next is Barking Reach, what is the state of that?—Barking Reach is very muddy from Margaretness on the north side to Crossness upon the south side, and from False Point as far as opposite Dagenham, upon the north side.

8981. Does that extend across the river, or is that upon the side?—It extends very nearly across at one point.

8982. Does that vary at all?—Slightly, near the lower end of the reach it varies.

8983. Again, when you speak of it varying does that vary at different times of the year or in different years?—It is rather in different years, because we do not survey it every year. In the different surveys we find that there is a different depth.

8984. What is the condition of Halfway Reach?—Halfway Reach is extremely muddy, especially all along the south side where the southern outfalls are.

8985. (*Sir John Coode.*) What depth of mud should you say there is there?—It is 9 or 10 feet far out into the river, and that mud is extending gradually down to the lower end of the reach.

8986. It is extending further down the reach?—It is extending further down the reach.

8987. Upon the south side?—Yes, upon the south side, and it is extending further out into the centre of the river.

8988. How often do you test it?—We have occasionally soundings taken here and there every year, but regular surveys throughout the whole reach every two or three years; we used to have them every year.

8989. What do you find upon the north side?—There is also mud off the north side opposite Jenningtree point.

8990. (*Mr. Lumley Smith.*) The next reach is Erith Reach?—Yes, from Jenningtree point down to Erith, all down the Kentish side of the river, is muddy; there is a great quantity of mud and of great depth towards the lower end of the reach.

*Sir John Coode* (*to Mr. Webster.*) Are you going to give the Commission any evidence as to the character of the mud.

(*Mr. Webster.*) Yes.

8991. (*Mr. Lumley Smith.*) At the lower end you come to the town of Erith?—Yes.

8992. What do you find there; is there any mud?—There is a very great deposit, 6 or 7 feet deep.

8993. To what distance does that extend into the river?—It goes about a third of the way across there.

8994. Has that varied at all?—It has rather increased lately—the latest soundings show rather more mud there than there had been before.

8995. And now we come to Erith Rands?—There is not much mud round Erith Rands, until you come to Crayfordness, and then down Long Reach you find mud in the very centre of the river.

8996. Below that point, you have no knowledge from actual surveys?—No, I have not.

8997. Does your observation enable you to speak of what there is between high and low water mark?—Between high and low water-mark there is a great deal of mud all the way down past Gravesend.

8998. Is that mud found in places which you have known for some years?—I know places which I can remember quite clean, or at all events so that you could land from a boat without difficulty, where you have now 3 or 4 feet of mud.

*Mr. C. J. More, M. Inst. C.E.*

13 Feb. 1883.

8999. Are you able to tell us in a general way, or in more detail, where the chief changes have been—does the mud shift much from time to time?—No I do not think it does, it keeps pretty much in the same places; the depth may slightly vary, but the locality is pretty much the same.

9000. It is not that you find one place clean that was muddy before, but practically it remains pretty much in the same place?—Yes, except that it extends in area year by year.

9001. Are you able to specify any particular parts in which the increase has taken place since you have known the river?—It has increased mostly in the neighbourhood of the outfall in Barking and Halfway Reaches.

9002. I do not know whether you are able to tell us anything of the character of the mud?—I can only tell you that it is a very black slimy sort of a mud. I know nothing about it chemically.

9003. Do you know the mud which is found higher up or lower down the river, some considerable distance from the outfalls—is it the same class as that, or not?—It is blacker, and of a more offensive character near the outfalls than elsewhere in the reaches; it is very much complained of by the men who are engaged by the Conservators to raise anchor, and wrecks; they complain of the offensive character of the mud which comes up in those reaches.

9004. (*Chairman.*) Do you know the character of the Medway mud?—No.

9005. (*Mr. Lumley Smith.*) Now you use the expression "in those reaches"—what reaches are you speaking of?—All the way down the river, even down to Sea Reach, I am told that mud of this description covers the articles which they bring up.

9006. Is that of more recent origin?—I do not know of my own knowledge, but they tell me that it did not use to be so.

9007. (*Sir John Coode.*) What is the date of any survey you have before the opening of the outfalls?—The only survey we had then is that of 1861, which began above the northern outfall and extended down the river.

9008. Could you show the Commission any chart showing the area of the mud in 1861, to compare with the one you have now put in?—I cannot, because upon that chart they have not indicated each sounding—they have simply put an occasional "G" for gravel and sometimes an "M" for mud.

9009. The notes with regard to the bottom were only occasional?—The notes with regard to the bottom were only occasional.

9010. (*Mr. Lumley Smith.*) From your own observation, are you able to speak to the offensive character of the mud?—Yes, I have noticed it frequently in the summer time; there is a most offensive smell in these reaches from the water; there is no doubt about that.

9011. When you say "these reaches," which do you mean?—I have smelt it even at Woolwich when I have been waiting for my boat, when it has been stirred up by a steamboat, and there has been a horrible smell, but in the winter there is no smell, except just by the outfall.

9012. Then it is the increase of the temperature in the summer months which makes it offensive?—Yes.

9013. Have you seen sewage going up stream at all?—I have seen sewage running out from the northern outfall up to low water—in a small stream, not in any quantity.

9014. Would that be frequently the case or not?—Yes.

9015. Whatever got out there would be of course carried up by the flood?—It would go up at once.

9016. Are there any other nuisances or matters of an offensive character that you could tell us of which you have seen with regard to these outfalls?—No, I think not, beyond what I have said already.

9017. You have prepared sections, have you not, of the bed of the river; are those what you have been showing to the Commission?—It is not a section, it is simply a plan of the bed.

9018. What years are they for?—One of them, the Barking and Halfway Reach, is for 1882, the others are for 1877, 1878, and 1879, the latest surveys that we have.

9019. Have you prepared any sections for previous years?—Not in the neighbourhood of the outfalls.

9020. Now, have you prepared sections at Erith Rands?—I have sections; we were asked for all sections of the river. Captain Burstal produced a section of a portion of the river, and I have prepared a section right across the river.

(*The same were handed in. See Appendix* A A.)

9021. As I understand, Captain Burstal had produced a section which showed a change upon the south side?—Yes.

9022. And my learned friend, Mr. Bidder, wished to have the section plotted throughout, so as to show what change had taken place throughout?—Yes.

9023. You have produced those sections; now, for what years are they?—They are for the years 1832, 1861, and 1882.

9024. What alterations, speaking generally, do they show at Erith Reach and the Rands?—They show a good deal of dredging between the years 1832 and 1861.

9025. That would be before the opening of the outfalls?—Yes, before the opening of the outfalls.

9026 Do they show any accumulation of mud in 1882 since 1832 upon the south side?—Yes a very large accumulation.

9027. When has it taken place, between 1832 and 1861, or between 1861 and 1882?—Between 1861 and 1882, most of it.

9028. And when was the dredging principally done?—The greater part of the dredging was done between 1832 and 1861; at some part of that period, but I do not know exactly what part of that period.

9029. Now, did you take any part in the float experiments which have been brought before the Commissioners?—I did not take any part in those experiments.

9030. But you are familiar with the run of the tide in the different reaches, are you not?—Yes, I have taken float observations in the reaches near the outfalls some time ago.

9031. Were they taken in the same way, with the same class of float as has been used upon this occasion?—They were not taken for the same purpose as the float observations were taken upon this inquiry; they were taken for the purpose of observing the set of the currents, and not for the purpose of observing the distance an object would float with the tides.

9032. When you come to the crooked parts of the river above Long Reach, do you find that the flow of the stream is variable there, or equal all the way up?—It is very variable indeed.

9033. More so than in the lower reaches?—Yes, much more so.

9034. What is the difference—are there eddies?—There are eddies of different velocity round the points and upon different sides of the reaches, and at different points of the reaches.

9035. May I take it that objects in the reaches would be more subject to the influence arising from the shape of the reaches than objects outside the reaches?—Yes.

9036. Would that account for two floats that are in the same reach, making different journies?—Yes; it would depend entirely upon the particular stream they got into; if one got into an eddy, it would remain there for some considerable time.

(*Mr. Bidder.*) I would suggest, after what Mr. Mansergh said, whether it is worth while following the floats any further. Mr. Mansergh said that they showed how the water oscillated up and down, but not how the whole body of the water moved.

(*Chairman.*) I was going to say that the experiment

shows a result which is a perfectly honest one, but it also shows a result which is a fallacious one.

(*Mr. Lumley Smith.*) It does not, of course, show that the main body of water will always move as a particular float did.

(*Mr. Bidder.*) There is no dispute between us that the water in the Thames, be it sewage or ordinary water, does not go straight away to sea, but oscillates up and down much as the floats might have done; but as both the witnesses have admitted that the floats are no guide as to the way in which the water or sewage reaches the sea, I think we had better bury them.

(*Chairman.*) Can they mend your admission of half a mile a day?

(*Mr. Bidder.*) They make it rather more.

(*Mr Lumley Smith.*) The floats, to a certain extent, show what the condition of the sewage would be in the river; that a portion of it oscillates up and down. They do not prove the extent to which each day the sewage gets out to sea, but they do show what happens to the sewage when it gets into the river.

(*Mr. Bidder.*) If my learned friend is going to rely upon their showing anything more than that the water of the river oscillates up and down, I shall be obliged to go into it, because I shall be in a position to show that it depended very much upon the number of public houses upon the banks how far they made progress in any particular direction.

At this point Sir P. Benson Maxwell took the chair.

Cross-examined by Mr. Bidder.

9037. Now you are the engineer to the Thames Conservators?—I am.

9038. Therefore I am right in saying that you gave all this evidence, and, perhaps, I might add a little more, upon the last inquiry?—Yes, I did.

9039. And you put in practically the same sections and pointed out the same mud banks?—Very much so.

9040. And you asked the arbitrators upon that inquiry to draw the same conclusion that the mud came from the sewers?—I believe they were asked to do that.

9041. Now with reference to the Erith Bank, about which you have handed in sections to-day, and which I have in my hand, just tell me this, as I have been looking at the sections, do they not show that between 1861 and 1882 there had been principally upon the north side of the river at that point, very considerable excavations and deepening of the river?—Yes, there had been, undoubtedly, upon the two lower sections.

9042. So that contemporaneously with the growth of the mud bank upon the south side of the river there had been deepening by dredging operations upon the north side?—There had been dredging undoubtedly.

9043. Exactly the same process has been going on, as we showed had been going on with regard to the three banks above upon the last inquiry?—Yes, the dredging had been going on during that time.

9044. I think you admitted upon the last inquiry, and you will admit again, that at each of those points, at Barking, Margaretness, and Halfway Reach, it was true that mud banks had been growing, but it was equally true that contemporaneously with the growth of the mud banks there had been enormous dredging operations carried on by the Conservators of the Thames upon the opposite side of the river?—There had been dredging operations carried on, not by the Conservators, but by other people.

9045. Under their sanction at all events?—Yes.

9046. As the result of the river being deepened artificially on the one side, and silting up naturally on the other, the sectional area was increased?—Yes; but it was not upon one side alone that the dredging took place.

9047. Still the result was on the whole that the sectional area was increased?—The sectional area was increased, there is no doubt about that.

9048. And you adhere to that still?—Yes.

9049. Now you said just now that the river was offensive in the summer, I should like to ask you, at what part of the river you say that there is any apparent offensiveness?—Woolwich Reach is a very offensive place in hot weather, and from there down to Erith Reach.

9050. That, you say, you observe when steamers stir up the mud?—Undoubtedly, when a steamer, our steamer, for instance, stirs up the mud with her paddles, the effluvium is extremely offensive.

Re-examined by Mr. Lumley Smith.

9051. My learned friend asked you some questions with regard to the sectional area being increased; dredging had taken place, you said, opposite Erith Rands?—I was speaking of the part opposite the southern outfall.

9052. When you said the sectional area was increased, what period were you speaking of then?—It must have been going on for some time. I think the first attempt to do anything there was in 1863, very little was done then, and then after that, whether it was 1866 or 1867, I do not remember the dates exactly, but off and on for several years, there was a good deal of dredging done there; it was the removal of the shoal which was called the Dagenham Shoal.

9053. There is an accumulation of mud upon the opposite side?—A very large accumulation indeed.

9054. Has that accumulation of mud more than counterbalanced the increase of the sectional area, which was due to the dredging; are you speaking of what was due to the dredging without taking into account what was added by the mud?—Yes, if you dredge you must increase the sectional area.

9055. (*Mr. Abernethy.*) Has there been any dredging upon the northern side, opposite the southern outfall?—No, not since the date of the last inquiry, I should say, and the accumulation is still going on.

9056. You do not say the sectional area had increased, having regard to the deposit of mud?—No, I say if you dredge, the sectional area must be increased.

(*Mr. Bidder.*) My question to the witness was directly with regard to this point. Whether comparing the river now with what it was before the silting began, the sectional area had increased, and he says—"undoubtedly, if you dredge you increase the sectional area."

(*Mr. Abernethy.*) Where has the dredging taken place in recent years.

(*Witness.*) In recent years it has taken place mostly in Erith Reach.

9057. And there has been no dredging opposite the Crossness outfall for three years past?—No, not in that particular part. I think it was before 1879 that the dredging was done there.

9058. (*Mr. Bidder.*) In this part of the river, where you say mud is deposited, comparing the sectional area of the river with the dredging and with the mud as it exists, with the sectional area of the river before the mud and before the dredging, is not the sectional area greater now than it was before?—Compared with what—the year 1861, do you mean?

9059. Take the sectional area of the river as it is now dredged in part and with the mud, comparing it with what it was in 1861 before the dredging and before the mud, is it not greater now than it was then?—I cannot answer that question right off. I could give you the actual areas, but I cannot answer

*Mr. C. J. More, M. Inst. C.E.*

13 Feb. 1883.

that comparative question. I understood your question to be, whether the sectional area had not been increased, and that therefore the mud came there in consequence.

9060. (*Chairman, Sir Benson Maxwell.*) Mr. Bidder understood that plan of yours to show that there had been an increase?—I can give you the exact figures, but I have not them with me at the moment.

(*Mr. Bidder.*) I wish you to understand that I am taking the river as it is dredged in part and with the mud silted up.

9061. (*Mr. Abernethy to the witness.*) You gave your answer to Mr. Bidder with regard to a certain section of the river?—Yes, opposite the outfall.

9062. Then your answer was not a general answer with regard to the river generally?—No, it related to that particular part.

(*Mr. Bidder.*) My question was a general question with regard to all the reaches of the river that the witness has particularised.

(*Chairman.*) I understood you to refer to that particular one.

(*Mr. Bidder.*) No, I put it with regard to all the reaches, Erith Reach, Barking Reach, and Halfway Reach; whether it was not in every case true that the sectional area was largely increased.

(*Witness.*) I must have time to look the matter up before I answer the question.

9063. (*Mr. Lumley Smith.*) Then apart from the fact that the dredging, for the time being, increased the sectional area, you cannot tell us for the moment what the change has been?—No, I cannot.

9064. Of course we may take it that the accumulation of mud has diminished the sectional area?—Yes certainly.

The witness withdrew.

Mr. James Mansergh recalled and further examined.

*Mr. J. Mansergh.*

(*Witness.*) Mr. Bidder asked me if I knew whether the areas in Halfway Reach in 1882 were larger or smaller than they were in 1861, and I said that I had not the figures with me at the time, but now I have them; this was with regard to the constriction that was alleged. I have it with regard to eight sections, and I will hand in that table (*having measured*), they extend over a mile and an eighth of the river, between 5 W. and 2 E. I will give you first the cross-sectional areas in 1861, cross-section 5 W.

9065. (*Sir John Coode.*) That is, according to your section, about 1,400 yards above zero; but that is not opposite the southern outfall?—It is in Halfway Reach, in the middle of the bank.

9066. We will take it as being measured from the southern outfall; 5 W. is about 900 yards above the southern outfall, and 2 E is about 1,100 yards below the southern outfalls?—Yes, that is so. If you will allow me to give the sections at the same time, as they are printed in the Mud Case book they can be referred to; it is at page 616; in 1861 the 5 W. section had an area of 29,866; and in 1882 it had an area of 28,419 square feet; so that now it is a little smaller there. In 1861, the 4 W. section had an area of 31,386 square feet, and in 1882 it had an area of 31,297 square feet, so that that is a little smaller now. The 3 W. section had an area in 1861 of 33,529 square feet, and in 1882 it had an area of 32,845 square feet; that is also smaller. In 1861 the 2 W. section had an area of 31,427 square feet, it has now an area of 32,439 square feet; that is now a little larger. The 1 W. section had in 1861 an area of 27,586 square feet; it has now an area of 28,397; that again is a little larger. The zero section had in 1861 an area of 28,140 square feet, it has now an area of 28,094 square feet; that is a little smaller, practically it is identical. The 1 E. section in 1861 had an area of 32,369 square feet, it has now an area of 29,488 square feet; that is smaller. The 2 E. section had an area in 1861, of 33,278 square feet, while in 1882 the area was 30,958; that is also smaller.

9067. (*Mr. Lumley Smith.*) The one where you said there was a considerable reduction is a little lower than the outfall?—A little lower down.

9068. (*Mr. Bidder.*) The figures of 1882 are, of course, new figures, introduced since the last Inquiry; but at what time of the year were these figures taken?—Mr. More can tell you better than I can; it was in 1882.

9069. You know that in any particular mud bank the sectional area varies at different times of the year, according as there is more or less flood water?—No doubt.

9070. You may get a sectional area at one time of the year which will differ from that at another time of the year?—You asked me the question; I did not volunteer the information.

9071. What are the bases of your 1861 section?—The Conservators Surveys of the 1861.

9072. I cannot quite follow it; you said when you put them in before, in answer to the question put by Captain Galton, "Those are the sections in 1861?" —Yes; the same numbers apply"; then at question 6802 you are asked "The composite section is the one "upon which the hydraulic mean depth is worked "out," and your answer was "Yes"?—The 1861 sections I now refer to are the sections of the river before the Dagenham Shoals were removed, and of course before the mud was deposited.

9073. And I daresay you will tell me this as you told me at question 6815 in the Mud Inquiry, when I said "tell me frankly now what it will show; it is useful "for the arbitrators to know" and you said "It "shows that the river was made a little large in the "Crossness Bank," there is no doubt that the river was made too big at that point by dredging?—No doubt, but it has grown up since.

9074. (*Mr. Lumley Smith.*) This year 1882 has been a very wet year?—Yes.

9075. Would that tend by the increase of the flood water to increase the sectional area?—No doubt it would tend to increase the sectional area, but I cannot tell at what time these sections were taken.

The witness withdrew.

Mr. Charles James More recalled and further examined.

*Mr. C. J. More, M. Inst. C.E.*

9076. (*Mr. Lumley Smith.*) Could you now answer the question which Mr. Mansergh could not as to the time of year when these cross-sections were taken?—Those would be taken about September of last year.

9077. That was a time when the flood water came down?—There was a good deal of rain over the whole of the year—it was a wet summer. I did not take them myself.

9078. (*Sir John Coode.*) According to the diagram put in, the quantity of water coming over Teddington Weir in the month of September was very small; it was a very dry month—the water did not begin to rise until the middle of October?—The survey began about the beginning of August and they got down to Erith, and it was such bad weather that they could not get on with it, and they did not finish until November.

9079. (*Mr. Lumley Smith.*) When they got below the outfall did the bad weather come on?—I could not speak to that myself.

(*Sir John Coode.*) The diagram which has been put in will show us exactly the quantity of water going over Teddington Weir day by day.

9079*a*. (*Mr. Lumley Smith.*) You stated that you were able to give us some figures—will you now do so?—These (*producing some tables*) are the areas of the cross-sections I put in a little while ago.

(*The same were handed in, and are as follows.*)

Areas of Cross Sections of the River Thames.

(ERITH.)

| Section. | 1832 S. feet. | 1861 S. feet. | 1882 S. feet. |
|---|---|---|---|
| 725 feet above beacon at low water | 35,343·20 | 46,072·80 | 42,829·80 |

9080. This table gives in parallel columns in square feet, the areas of the cross-sections in 1832, 1861, and 1882 ; that is so, is it not ?—It is so.

9081. At certain places which you have mentioned on those diagrams ?—Yes.

9082. This table gives the increase and the decrease at those various places in the two intervals, from 1832 to 1861, and from 1861 to 1882 ?—Yes.

9083. It is putting into figures, which will appear upon the notes, the points which appear in your section ?—That is so.

Further cross-examined by Mr. Bidder.

9084. You assisted, as we know, at the last inquiry, Captain Calver, who was the gentleman called in to report upon that part of the river ?—Yes, I was with him a good part of the time.

9085. You supplied him with materials for cross-sections and surveys upon which he made certain calculations as to the contents of the river ?—Yes, they were taken from our surveys.

9086. On that occasion you divided the river into five sections running from a little above the Barking outfall down, I think, near to Erith ; one north, and one south ?—Yes, I remember what you mean.

9087. I do not know whether you have any plan with you now showing it, but I think I am right in saying that you numbered the river into five divisions, beginning with No. 1 division at a little above the Beckton Gasworks, and then going down. No. 1 contained the outfall upon the north side, and No. 2 was the intermediate piece between that and Leather Bottle. No. 3 contained Leather Bottle ; No. 4 contained the Southern Outfall, and No. 5 contained Jenningtree ?—That was so.

9088. Do you recollect preparing and putting in calculations from your sections of the low water content of the river in each of those divisions ?—They were put in, but I had nothing whatever to do with them.

9089. Is it the fact that, comparing 1861 with 1879, every one of these divisions showed an increase of content ?—I had nothing whatever to do with these tables, either with the calculation of them or putting them in or anything.

9090. Pardon me, all the calculations with regard to the increase or decrease of the content of the river were got out by your staff and you for Captain Calver ? —They were got out for Captain Calver, but not by me. I know nothing about them.

9091. He mentions in his report with becoming gratitude the services he received from you ?—We furnished him with the Surveys from which these calculations were made.

9092. Do the figures prepared from your survey show that the content of every single division of the river was increased from 1861 to 1879 ?—They are not my figures.

*Mr. Lumley Smith* objected to the line of examination.

9093. (*Mr. Bidder.*) Were they not prepared by you and your staff and in your office for the purposes of Captain Calver's report ?—Excuse me, they were calculated outside of our office entirely.

9094. (*Chairman.*) What are you referring to ?—I am referring to a report by Captain Calver, at page 7.

9095. (*Mr. Bidder.*) I see you said upon that Inquiry that you were with Captain Calver during the whole time that he made the surveys and investigations ?—Yes, I was, undoubtedly, most of the time.

9096. And he was, as I said he admitted in his preface, assisted by yourself and staff in his survey, and your office was the only place from which he could get the materials ?—The materials were obtained from our place ; our office is the only place in which he could get the materials to make the calculation.

9097. And his table shows that every single division in the river increased from 1861 to 1879.

(*Chairman.*) But the last column in the table is for the year 1876.

(*Mr. Bidder.*) That is so in the printed report, but I can find in the print of the Mud Inquiry the further years, if it is thought desirable.

(*Witness.*) I find they did as a rule, but upon the south it is not so.

9098. But you must take the north and south separately, because it so happens that the dredging was upon the north, and the silting up upon the south. Now, taking north and south together, do not all of them show an increase ?—I think it is quite correct as you put it ; it is so, no doubt.

9099. (*Mr. Abernethy.*) Between 1879 and 1881 were not there a number of shoals removed from the river near the outfalls by dredging ?—Yes, there were.

9100. And in other reaches too, were not there ?—No, not in Dagenham, not after 1879 ; but there were extensive dredgings in Erith Reach.

Further re-examined by Mr. LUMLEY SMITH.

*Mr. C. J. More, M. Inst. C.E.*

13 Feb. 1883.

9101. Let me understand about these figures which my learned friend has put into your hands. Are those figures at all calculated by you?—No.

9102. Certain surveys had been taken in your office?—Yes.

9103. And those figures have been calculated from the surveys, and have you examined them, or tested them, or checked them, or do you know anything about them?—I do not say they are not right; I simply say I know nothing about them, I had nothing to do with them.

9104. You handed in figures to-day, showing an increase at Erith?—Yes.

9105. Does that appear at all in the district embraced in that table of figures?—No, that is further down the river.

9106. Does it appear from this table at the places you have taken, viz., at Erith 725 feet above the beacon, and 280 feet above Sand Wharf, that there was an increase in the sectional area between 1832 and 1861, and a decrease between 1861 and 1882?—There is an increase opposite Erith town causeway between 1861 and 1882, but the others all show a decrease.

(*Mr. Bidder.*) But Erith town is just one of the very places at which they complain so much of the mud having accumulated.

9107. (*Mr. Lumley Smith.*) Is that a part where dredging has taken place?—Yes, dredging has taken place in that reach, undoubtedly.

9108. In the section immediately opposite the causeway there has been an increase of sectional area?—Yes.

9109. Is there anything specially to cause that increase opposite Erith causeway; is there any dredging or anything there?—There has been dredging in that reach, no doubt.

(*Sir John Coode.*) It was distinctly put in evidence at an early part of the Inquiry that there had been dredging upon the northern side of the river opposite Erith.

The witness withdrew.

Mr. R. W. PEREGRINE BIRCH, Mem. Inst. C.E., examined.

*Mr. R. W. P. Birch, M. Inst. C.E.*

9110. (*Mr. Balfour Browne.*) You are a member of the Institution of Civil Engineers, are you not?—I am.

9111. If I may so put it, I think you served your time with Mr. Abernethy?—I did.

9112. And in that way, I think, you have had considerable experience in all tidal questions?—I have given my mind to them for several years.

9113. And since you have been practising on your own account, have you given considerable attention to questions connected with the disposal of sewage?—I have.

9114. Were you engaged by the Port Sanitary Authority to make certain tidal observations in the Thames?—I was.

9115. And were the gaugings as to a number of the tributaries put under your charge too?—A portion of them.

9116. And certain instructions in writing were given you, were they not, by Mr. Baldwin Latham?—Yes, as to the float experiments.

9117. And those experiments, if I am not mistaken, Mr. Baldwin Latham put in?—Yes.

9118. By the 7th of September last, had arrangements been made for the daily gauging of all the streams between Barking and Southend?—Yes.

9119. On which side of the river?—On both sides; between Barking and Southend on the north, and between Northfleet and the Isle of Grain upon the south, that was the part under my care.

9120. When did you commence your tidal observations?—We tried to commence upon the 14th, but we got into full working order upon the 17th.

9121. Those operations were under your immediate superintendence?—They were.

9122. And in order to watch them, I think you took up your quarters on board a steam tug called the "Toby"?—I did.

9123. And you were up and down the river watching the men at work for about two months?—I should think that I and my assistants were looking at them for from 18 to 20 hours a day during that time.

9124. And you slept on board the tug?—Yes.

9125. There were six floats, as we know, at the time, and the observations were carried on day and night?—Yes.

(*Sir John Coode.*) Do yo mean that there were six started from each station.

(*Mr. Balfour Browne.*) No; there were six floating in the river at a time.

9126. (*To the witness.*) Only one float was started at a particular time or a particular place?—One float was started upon the 17th of September at high water, another one at half ebb, another one at low water, and three more under similar conditions of the tide on the 22nd.

9127. And you had under your charge a gang of watermen, had you not, whose duty it was to follow those floats in a boat?—Yes.

9128. To each float there was a boat and two men attached, that is to say, attached in the way of watching?—Yes, two men for the day and two men for the night.

9129. And the men who were to relieve, that is to say, the men who were to go on at night, where were they during the time they were off duty, were they on board your tug?—Some of them; or they would go home. We relieved the men by means of the steamer sometimes, and sometimes they came by train to the point at which they were to take up their duty.

9130. Do you believe that the experiments were fairly and properly conducted by those in charge of the floats?—Yes, I believe they were fairly conducted.

9131. Had you brought to your knowledge a single case of misconduct on the part of the men?—No; except that when we discharged a man, we have heard that he had gone to the other side and made mischief; we had heard that, but I never could trace any trickery at all to anybody.

9132. Did you ever dismiss a man for tampering with a float or attaching it to his boat?—Before the 17th we did, but not afterwards.

9133. But not in any of the experiments of which the results are shown in these notes?—No.

9134. Now, according to the papers put in by Mr. Baldwin Latham, they show that whereas the morning ebb is almost always longer than the morning flood, the reverse is the case with the afternoon tide?—Yes; it should be borne in mind that the division between morning and afternoon tides is not a division between the daylight and dark tides. I divided the whole of the diagram out into daylight and darkness to see if I could detect any trickery in the dark, when it is manifestly more difficult to supervise such a job as that than in the day, and I could not find any such thing, and I think if any gentleman on the Commission will look through the diagram, he will see that the floats have behaved very much the same in the dark as they did in the daylight.

9135. Then that fact of the run on the morning ebb being longer than on the morning flood, and the reverse in the afternoon, cannot be explained by any trickery upon the part of the men employed?—Not at all. If there is any trickery proved by the other side, as I gave my whole time to the subject, it will be due to my carelessness, more or less. I have met the men in London at 4 o'clock in the morning and at other places when they did not expect me. I have seen them from the bridges; they had always been told that they had friends watching them and enemies watching them, so that I do not think there could have been much trickery of the kind going on.

9136. You have taken every possible means to avoid it?—Certainly.

9137. With regard to the six floats which you have been mentioning to the Commission, does the distance travelled upon any particular tide represent the maximum or the mean range of the tide?—No.

9138. Will you just explain what it does represent?—The floats were left to take their own course entirely; they were only pushed off when they were likely to touch the shore, so that during a portion of their course they may have been in the best of the tide, but certainly some lateral influence moves them constantly, and they will move from the best of the course to the worst of the course, and from the centre of the course to the side of the course, so that you cannot say that they are in the best of the stream, or in the mean of the stream, or in the worst of the stream.

9139. I need not take you particularly over all the deductions which are to be drawn from the conduct of the floats, because those points have been more particularly gone into by Mr. Baldwin Latham; but I think you will agree with me in this, that the floats, by themselves, are no criterion of the progress of the sewage water towards the sea?—No, not a bit; no one thought they were.

9140. That is evident, because No. 1. was no nearer the sea after it had been in the river for a month than it was when it was put in?—Not at all.

9141. Now, with regard to certain anomalies that appear upon the face of the diagram, is it the fact that the floats upon a flood tide are less affected by lateral influences, such as wind and irregularity of course, than the floats upon the other tides—the neap tides?—Yes, I think it is the greater velocity of the flood tide which accounts for the floats taking a more direct and better course, and therefore a longer journey upon a flood tide than upon an ebb. There is no doubt that the flood tide is considerably faster than the ebb, for this reason. We know that a larger quantity of water comes down with the ebb tide than goes up with the flood, but the time that it takes to come down is increased in a much larger degree than the volume is increased. I have taken the tide of the 1st of October, and I find that at Barking the period of flood upon the 1st of October was 327 minutes, and the period of ebb was 418 minutes. The total volume of water between high water mark and low-water mark above Barking was 2,224,381,325 cubic feet, and during that 12½ hours there was 114,611,250 cubic feet of fresh water, that leaves 2,109,770,075 cubic feet as coming from the sea.

(*Mr. Michael.*) Does that quantity that came over Teddington Weir upon that day, namely, the 114,000,000, represent that water which came into the tidal portion of the river between Teddington and Barking.

*Witness* (*continuing*). The fresh water increases the quantity of water which came from the sea upon the flood tide by about 5¼ per cent., but the time occupied by the ebb tide is 418 minutes against 327 minutes occupied by the flood, so that the relative velocities of the flood and ebb would be as 100 divided by 327 to 1,054 divided by 4,180, or as 30 to 25; the flood tide is therefore 20 per cent. faster than the ebb.

9142. You have put that in a tabular form, have you not?—I have.

*The same was handed in and was as follows:*

*Mr. R. W. P. Birch. M. Inst. C.E.*

13 Feb. 1883.

Figures showing that the velocity of the *Flood Tide* at Barking is greater than that of the *Ebb Tide*.

(Taken from Erith and Deptford Tide Guage Diagrams, referring to 1st October 1882.)

Low water at Barking 10.4 a.m.

| | | | |
|---|---|---|---|
| High water | do. | 4.10 p.m. | Interval 327 minutes. |
| Low water | do. | 11.8 p.m. | Interval 418 minutes. |

Total volume of water above Barking, between Barking high water and Barking low water line = 2,224,381,325 cubic feet.

| | |
|---|---|
| Made up of land water* | 114,611,250 „ |
| And tidal water | 2,109,770,075 „ |

The volume of ebb from above Barking on this day is consequently, by reason of the land water, 5·4 per cent. greater than the previous flood. But the time occupied by the ebb is (see above) 418 minutes against only 327 minutes taken by the flood.

The relative velocities then of flood and ebb will be as $\frac{100}{327}$ to $\frac{1054}{4180}$ or as 30 to 25. The flood is therefore 20% faster than the ebb.

* 152,815 cubic feet per min. × 12½ hrs. × 60 min. = 114,611,250 cubic feet in the tide.

9143. That, I understand, shows that the velocity of the flood tide is greater than that of the ebb?—Yes.

9144. Will that, to your mind, account for the floats taking a better course and a longer journey, up the river than down?—Certainly.

9145. If the flood tide is the stronger it would minimize the effect of the wind or any other obstruction?—Yes.

9146. So that a good many of the anomalies would be accounted for by the true course kept by some of the floats, while others have not kept so true a course?—That is so, it is entirely a matter of steering.

9147. And the men were not allowed to steer a float, but only to move it when it got aground?—That is so.

9148. Then would it go to show that the up tide being stronger than the down tide, would have the effect of carrying up any deposit from the mouth of the outfall and depositing it higher up the river; is that the tendency?—Certainly it would.

9149. What is the agent which principally effects the scouring in the river; is it tidal water or is it fresh water that comes over Teddington Weir, and falling into the river with that of other tributaries below?—It is the new water; the fresh water from the river and the new water from the sea that carries away the sewage.

9150. Not the water which is swaying backwards and forwards, and knocking about?—No, certainly not.

9151. What proportion does the upland water form of the total water that would scour out the sewage. Have you come to a conclusion as to that. You say that the upland water plays the important part in scouring out the river?—My point is, that the amount of water oscillating between Crossness and Barking, though it may have a great scouring power upon the bottom, has no effect in carrying out the water and sewage to the sea; it is simply the shaking of a vessel which is being filled upon the one side and emptied on the other: but the shaking of the vessel has no effect upon the emptying or the filling.

9152. Then upon what circumstances would the quantity of sewage leaving the river depend?—Upon the quantity of fresh water coming in.

9153. That, of course, depends upon the up country rains, and the character of the tides at the time?—Yes, quite so.

9154. Have you worked out the particulars for three distinct days, the 14th and 22nd of September, and the 30th of November?—I have. I have worked out in diagrams what Mr. Latham and Mr. Mansergh worked out in tables.

(*Diagrams were handed in. See Appendices A.B.* 1, 2, 3.

9155. I think in one other circumstance you have varied your procedure from that adopted by those gentlemen. They took absolute high and low water,

*Mr. R. W. P. Birch, M. Inst. C.E.*

13 Feb. 1883.

and you have worked throughout upon the mean?—Mr. Latham and Mr. Mansergh are gentlemen with much greater experience than I am; but I have worked it out with great detail, and with every possible correction I could think of; and the result is practically precisely the same.

9156. You have worked it out in another way and have arrived at very nearly the same result?—Yes, there is hardly any difference between us.

9157. You have, I think, taken three distinct days. Now, there was a spring tide upon the 14th of September?—Yes, the tide upon the 14th of September was a spring tide.

9158. And what was the flow at Teddington Weir?—8,332 cubic feet per minute.

9159. The 22nd, which is upon the second diagram, was a neap tide with rather more water over Teddington Weir, the flow being 122,451 cubic feet per minute?—Yes.

9160. And the tide of the 30th of November was half way between spring and neap, was it not?—Yes.

9161. With a flow of 476,345 cubic feet?—That was a very great flood.

9162. Will you just explain your first diagram?—The first diagram shows the respective quantities of sea water, inland water, and sewage in the various reaches of the Thames upon the 14th of September 1882, and it shows that the northern sewage of the 16th of August, mixed with the Teddington water of the 4th of August, reaches Southend upon the 14th of September, taking 30 days to do the journey, the sewage, being when it arrives at Southend 30 days old, that is to say, from Barking to Southend.

9163. Your diagram begins to figure at Barking?—Yes, the sewage of the 16th of August gets to Southend upon the 14th of September, and the Teddington fresh water of the 4th of August gets to Southend on the same day. Every day's upland water and sewage which affects this diagram is localised longitudinally by the red lines across the white column, and its volume is shown in cubic feet by red figures upon each block, and each of those blocks is supposed to contain 26,000,000 cubic feet of sewage. From that the proportion of sewage in the river can be ascertained.

9164. What do the red figures at the north of that white indicate, September 1st and August 31st?—They show the day upon which each block of water came over Teddington Weir.

9165. So that beginning at the top, that water which arrives in Barking upon the 14th of September came over Teddington Weir upon the 2nd?—Yes.

9166. Take Erith; that water which arrives at Erith upon the 14th of September passed over Teddington Weir upon the 28th of August?—Yes.

9167. And so on, all the way down until you come to the very last, which shows that the water which was at Southend upon the 14th of September left Teddington upon the 4th of August?—Yes.

9168. Each block of water, as it carries the sewage of the day with it, passes through that column, accordas the column of tidal water comes back to displace it, and carry it to the sea?—Yes.

9169. This white column seems to diminish as it goes down?—Yes.

9170. So that apparently there is at Southend less fresh water than there is higher up?—There is a smaller column, but it is travelling faster.

9171. That is why the white seems smaller at Southend than it is up at Barking; the same amount is passing through, but it is going more rapidly, and therefore the sectional area is smaller?—Yes; this diagram shows all the fresh water as though it were collected to one centre. Of course, it is not so, it may be distributed in millions of fibres; but we have collected it all together and shown it as occupying that body of the channel; that is the only means, I think, of calculating the rate of progress of fresh water in any tidal estuary; this diagram is not, of course, a true plan, it is a developed plan.

9172. (*Sir John Coode.*) The width represents the proportionate sectional area of the river, if I understand you rightly?—It represents what width the river would be if it were one foot deep all over; that makes it appear much wider at the mouth of the river than it would otherwise do.

9173. (*Mr. Balfour Browne*). Now at Southend, you say it is the same quantity of sewage which is passing, but it is passing more rapidly and therefore of course filling a smaller sectional area?—Yes, quite so.

9174. To what do you attribute the greater rapidity of the column of water at Southend?—Because the sea water coming in reduces the cross sectional area, and as soon as you reduce that, if you have a regular supply of fresh water, you have *pro tanto* an increase of velocity.

9175. If you increase the sectional area of the river through which the fresh water and sewage have to flow, of course you would get the rate of progress slower?—Yes.

9176. On the other hand, if you decrease the sectional area by the coming in of the tide, you get it faster?—Yes. The long and the short of this diagram is that it shows that the velocity is not reduced as the river gets wider, as it would be supposing the whole of the river channel had to be filled up before the water could be displaced into the sea. But for the action of the sea water, the velocity at Southend would be a 12th of the velocity at Barking; but as a matter of fact the velocity at Southend is really a little faster than the velocity at Barking.

9177. That fact is also brought out, though not diagrammatically, in Mr. Latham's and Mr. Mansergh's tables by figures instead of diagrams?—Yes.

9178. What is all this founded upon; is it founded upon mere displacement or upon the chlorine tests?—It is founded upon the salt tests, which tell us how big the fresh water column is, and when we know how big the fresh water column is, we know how fast that fresh water column must travel to carry out a given quantity of water. Now it was suggested that we have taken the wrong standard.

9179. Is 1961 the wrong standard, or what do you say to it?—No; it is absurd to say that it is a wrong standard; we found on some days, at Southend, water with 1938 grains of chlorine in it, so it is quite clear that within the tidal range of Southend, there must be water quite as strong as 1960; and we also found at Margate salt water as strong as 1950 odd; we should not expect to find the saltest water close to the shore where a river runs down, but I have no doubt that in the centre of the estuary you would find that the water would have, as a normal quantity, 1960 grains of chlorine in 100,000.

9180. Is that figure 1961 corroborated by the figure I find in Mr. Way's tables, which Mr. Latham put in?—Yes it is.

9181. I find at Southend upon the 14th of September, that the chlorine in 100,000 parts of water was 1931 does that corroborate to your mind the accuracy of the standard of 1961?—Certainly; after this water has come up from the centre of this estuary to Southend and been mixed with fresh London water it still has 1931 parts of chlorine, and I cannot imagine that it could ever have had less than 1960 at Margate; to put it as low as 1700 would be absurd.

9182. On another day I find the chlorine at the same place, at Southend, is 1785; what does that indicate to your mind?—That there is a large quantity of upland water amongst it, as shown upon the later diagram. I think I should explain to the Commission that the line upon the upper side of the dotted line shows the limit of the high water capacity, the lowest hard blue line shows the low water capacity; and the two outer dotted lines and the two inner dotted lines show respectively the limits of the mean river capacity, and the mean fresh water column. It is a point which ought to be explained that the limits of the mean fresh water column are wonderfully near the limits of the high water column

upon the upper side, and to the limits of the low water column upon the lower side. If you look at the lower column of the 22nd it is especially so ; the mean line is very near the high water line upon the upper side, and very near the low water line upon the lower side, so I think we are justified in taking the mean as the average column of the day.

9183. Just to make these figures, which are put crossways upon the diagram, perfectly clear, you see it begins with 188,000,000 cubic feet?—That is upon the 14th of September diagram.

9184. That is the amount of water that came over Teddington Weir upon the 2nd of September?—Yes.

9185. The next happens to be the same?—Yes.

9186. That is only a coincidence?—Yes.

9187. The next again is 171,800,000, a smaller quantity came over on the 31st of August than upon the preceding two days?—That is so.

9188. (*Sir John Coode.*) Those are cubic feet in 24 hours, are they not?—Yes.

9189. Where were they taken from?—They were taken from Mr. Latham's tables, as far as the tables exist. We were obliged to take the earlier ones from heights that we could get from Mr. More, and we would say the water was 7 feet 6 high upon the 3rd of September, and it was the same height upon the 20th of September, and we know what the discharge was upon the 20th of September, and we take the same discharge as existing upon the 3rd.

9190. (*Mr. Balfour Browne.*) So that where you could, you have taken exactly Mr. Latham's figures, but, where it was necessary, you have supplemented them in the way you describe?—Yes, where Mr. Latham's figures exist, we have used them.

9191. This wave line represents upland water mixed with sewage?—Yes, you may get the proportion of sewage in the river in that way; you have 26,000,000 in 185,000,000, for example, that gives the proportion of sewage to fresh water, then you have 50 or 60 per cent. of fresh water by the side of the white block, which increases the proportion of the dilution which may be ascertained by measurement.

9192. Will you just turn to your No. 2 diagram, a similar process has been carried out there, only for the 22nd of September instead of for the 14th?—Yes.

9193. And this again represents the actual facts happening on that day?—Yes, the picture shows you exactly the quantity of fresh water there is in the river, and the statistics we have about the daily flows show you how that column must have been made up.

9194. And here again, we see that upon the 10th of September the water coming over Teddington Weir had arrived at Barking upon the 22nd of September, and that the water coming over Teddington Weir upon the 10th of August had arrived at Southend upon the same day, the 22nd of September?—Yes, having in it the sewage of the 22nd of August.

9195. (*Mr. Michael.*) But you have added 22, have you not, in every case?—No, it is a difference of 12 days, if you put the 22nd of September in the left hand division you will get 12 days.

9196. (*Mr. Balfour Browne.*) Because it took 12 days for the water from Teddington to come down to Barking, and then it got the sewage of Barking?—Yes ; upon the 22nd of September there are 12 days' fresh water in the river between Teddington and Barking.

9197. Now, with regard to diagram No. 3, that was taken upon the 30th of November; what was the condition of the river upon that day?—There was from four to five times as much water in it as in the two given days in September.

9198. That is to say, it was comparatively a flood?—Yes.

9199. The effect of that is shown diagramatically as compared with the last diagram?—Yes.

9200. What happened upon that day?—It shows that the sewage of the 19th of November reaches Southend upon the 30th of November. This is the only one which is not, upon the face of it, exactly the same as the table, or which does not give exactly the same result as the table. That is because Mr. Latham and Mr. Mansergh showed that it would take, upon the average, 13 or 14 days in that particular condition of the water, if there were an average flow equal to that of the 30th of November, but there was a greater flow before the 30th of November, and that greater flow reduces the number of days, but the fresh-water columns described in Mr. Latham's tables and Mr. Mansergh's tables are almost exactly the same as the fresh-water column in this case.

9201. This seems to show the greater importance of the sweeping out of the sewage to sea by the fresh water from the upland?—Yes.

9202. Might we go backward, and say that as the fresh water diminishes in the summer season these other two diagrams do not indicate the very slow progress which would then be made in the very hot and dry weather?—No, of course not, if you increase the velocity as we have shown it here, by an increase of fresh water, so you obviously increase the time it takes if you reduce the volume of fresh water in a hot summer.

9203. So that you would reason back and say, these mean periods were not at all indicative of what would take place in the height of summer?—Certainly not.

9204. But that a much longer period would be required to take the sewage down to Southend in a hot summer?—Certainly.

9205. (*Chairman.*) I understand your last table to show that upon the 30th water had reached Southend which had come over Teddington Weir on the 16th and passed Barking on the 19th?—Yes.

9206. So that there is only three days flow between Teddington and Barking in that case as compared to the 12 days which there had been in the former case?—Yes ; there was about from four to five times the quantity of water that there had been in the former case.

Adjourned to to-morrow at half past 12.

# TWENTY-SECOND DAY.

## Wednesday, 14th February 1883.

PRESENT:

THE RIGHT HONOURABLE LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANCOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary*.

MR. R. W. PEREGRINE BIRCH, Mem. Inst. C.E., further examined.

*Mr. R. W. P. Birch, M. Inst. C.E.*

14 Feb. 1883.

9207. (*Mr. Balfour Browne.*) It has been suggested that possibly yesterday you did not make clear enough to the members of the Commission the means by which you ascertained the progress of the upland water through the tidal estuary of the Thames, and, moreover, his Lordship was for a short time absent. Could you give just a simple explanation of the method you adopted which would make the matter clearer to the minds of the Commission?—I have prepared a short description of my view of the reasoning upon which I think the matter is based. We know from the gaugings of the river which have been made for several months the quantity of upland water reaching the tide way daily, and we know, taking one day with another, that as much water must go out of the river as comes in; so we may say that we know the daily quantity that passes through the river. So the question is, what speed that daily quantity must travel in order that the known quantity of water supplied to the river may be discharged. This would be a simple matter if we could see the column of water it formed running in a regular channel unoccupied by anything else, or falling over a weir so that we could measure its width and depth, for we should then learn by actual measurement the cross-sectional area of the column. It is the cross-sectional area that we want to get in order to get at the velocity. Then, by dividing the day's supply in cubic feet by the sectional area in square feet, we may ascertain with acuracy at once the day's progress towards the sea.

9208. That is if you could see the column?—Yes, if we could see the column; but we cannot see the column. Now, supposing the upland water supply to be 100,000 cubic feet per minute, this would pass through a column half a mile wide and 30 feet deep, if outside influences so dictated, just as easily as through a column twice as large; only, if it passed through the smaller column, the velocity would necessarily be just double.

9209. (*Sir John Coode.*) You mean through a smaller channel?—Yes, quite so. I call it column because it is not confined by any physical hard boundary.

9210. You are assuming a bulk of fresh water running through a quantity of salt water?—Yes; you get the same column of water running from a hose or jet, which has no physical hard limit, as you get inside a pipe, the diameter of which you can measure.

9211. If we can ascertain the cross-sectional area of the column we know the velocity at which it travels. We cannot, however, see the fresh water column, because it passes through a much larger mass of sea water, and so, to ascertain its size, we use salt tests which tell us what proportion of the whole mass of water is fresh water and (what is the same thing) give us the cross-sectional areas at a number of points down the river of the fresh water column. I do not know whether his Lordship saw the diagram we put in yesterday. I do not suggest that the fresh water passes through the salt water in one defined column, as is shown upon that diagram, for there is no doubt it passes away in myriads of small streaks; but the salt tests give us this combined volume, and, for the purpose of progress calculations, it matters not whether the fresh water be found in one large column or an infinite number of small streaks.

9212. If you could see the column, of course it would be all easy enough?—Quite so.

9213. But as you cannot see the column, then by the salt test you find how much salt water there is in the river, and therefore how much room is left for the fresh water?—Yes, we probe through the salt water until we come to the fresh, and find what room there is for the fresh water column. By ascertaining the amount of chlorine you learn the amount of salt there is in the water.

9214. Will you point out upon the diagram the portion of the channel occupied by fresh water at any point, and show the Commission how you arrive at it, taking one day of course; which day are you going to deal with?—The 14th of September (*placing the diagram before the Commission and explaining it*). We learn that the fresh water is $\frac{15}{1000}$ of the total water at Southend at high water; in the same way, at low water, the fresh water is $\frac{1}{10}$ of the total water. The mean fresh water bears the same relation to the mean salt water as that white space does to the blue between the dotted lines. We have applied the same process to an analysis made at five or six different points. We have interpolated the proportion of chlorine between the different points, and this is the result, that, as regards the progress calculations, we have a column of water represented by the white space instead of a column of water of this shape (*pointing to the blue*). The result is that the water travels even faster at Southend than it does at Barking, though there is a larger cross-section; the cross-section is twelve times as great at Southend as it is above.

9215. (*Chairman.*) What does this ultimately prove?—It ultimately proves that the sewage which went into the river upon the 16th of August reaches Southend upon the 14th of September—that is 30 days.

9216. That is to say, it reaches it for good?—Yes.

9217. And never comes back again?—No; that is the mean of the oscillation.

9218. Sometimes it is below Southend, and sometimes it is above Southend, but in the mean it is at Southend?—Yes.

9219. And is 30 days getting there?—Yes.

9220. (*Sir John Coode.*) The contrast between the white and the blue represents the relative volume of each?—Yes.

9221. This is rather of the nature of a sectional diagram than a ground plan?—Yes, it is not a ground plan. I explained yesterday that it represents the river as though it were a foot in depth, and of proportionate width. The Metropolitan Board of Works admit that it would go down only half a mile a day, but for something outside which makes it go faster. We think that we have dealt conclusively

with that outside lement to show how much faster it does go; that diagram is taken upon the 14th of September. This (*producing the second diagram*) is a very similar diagram taken upon the 22nd of September. There was rather more water then in the river than upon the average.

9222. Was the tide upon the 22nd spring or neap?—One is spring and the other is neap. For this month we must take the mean between the two for the progress, as they were not all neap, and they were not all spring tides.

9223. Upon which do you make it get soonest to Southend?—It depends on other outside influences.

9224. You mean to say that it depends more upon the volume of fresh water than upon the tide being spring or neap; that is the purport of your answer?—Yes. With regard to the tides we may take the mean between high and low water as a fair average of the whole day. Then when we come to the 30th of November we have a very different state of things. That means that there are three days between Teddington and Barking, instead of 12 days, as there were before. Upon the 30th of November we find that the rate of progress is altogether between Barking and Southend $11\frac{3}{4}$ days.

9225. The water which came over Teddington Weir on the 16th appeared at Barking on the 30th, and I see that the water coming over Teddington Weir on the 16th was 560,098 cube feet per minute?—Yes; this (*pointing to the diagram*) gives the daily flow in cubic feet. It is no part of our case to show how very rapidly the sewage goes out in flood time; but there is one inference from it which is in our favour, and that is that, if by increasing the quantity of fresh water you make the sewage go out so much faster, on the other hand, by reducing the quantity of water to the summer condition of things you make it go out so much more slowly.

9226. (*Mr. Balfour Browne.*) You had no opportunity of making one of these diagrams when the water in the river was going very slowly?—No; but I should like to have the thing done for weeks and weeks.

9227. You assume, seeing that it went out so rapidly upon the 30th of November, that in summer it would go out at a very much slower rate, though you have no means from observation of calculating the number of days?—No, I should not like to say what the rate of progress would be.

9228. (*Chairman.*) You could not take the average throughout the year, because if you had two months of almost stagnant water you would have mischief done then which could not be compensated by increased flow at another time?—Certainly not.

9229. (*Mr. Balfour Browne.*) Upon this occasion, the 30th, when it went out so rapidly, that was, of course, an occasion upon which there could be no nuisance from the sewage?—Of course.

9230. It is not during the month of November that a nuisance ever arises?—That is so.

9231. There is a point I was puzzled with upon the diagram No. 1. If you look at the white, which represents the sectional area of upland water and sewage, the column diminishes in thickness as you get to Southend?—It does.

9232. Why is that?—Because there is a large quantity of salt water which comes in from the sea and reduces the channel.

9233. The same quantity of fresh water must, of course, be passing through that section at Southend, but it is passing at a more rapid rate?—Yes.

9234. And therefore the sectional area it gets through must, of course, be smaller?—Quite so.

9235. Just to take one or two general questions upon these diagrams, looking at the one of the 14th of September, that shows that a certain amount of water and sewage was between Barking and Southend. What number of days flow of inland water and sewage would that represent?—30 days' sewage.

9236. There were 12 days' upland water above Barking?—Yes, the days between the 2nd of September and the 14th.

9237. That was water that had come over Teddington Weir 12 days before?—Yes.

9238. Now, as to the other diagram. Upon the 22nd of September, in the same way, how many days flow of inland water and sewage were between Barking and Southend?—32 days.

9239. That began upon the 10th of August, did it not?—Yes.

9240. And ended upon the 22nd of September?—Yes.

9241. What number of days flow of inland water was above Barking upon that date?—12 days.

9242. Now, passing to the 30th of November, how many days of inland water and sewage were between Barking and Southend upon that day?—$11\frac{3}{4}$ days, beginning upon the 16th of November and finishing upon the 27th of November.

9243. Then those diagrams, as I understand, show both the age and the amount of the dilution of the sewage?—Yes, quite so.

9244. In September, for instance, the northern outfall sewage passed Erith about from five to six days after it had been emitted; that is to say, when it was five or six days old?—Yes, from five to six days old.

9245. I think I heard you so explain to his Lordship that, altogether apart from its progress to the sea, the sewage has been swinging backwards and forwards over the 6 miles radius?—Yes, quite so. These blocks represent the centres.

9246. When it gets there it is on its final progress to the sea?—Yes.

9247. It was six days old when it passed Erith?—Yes.

9248. And was diluted upon the 14th by how many times the water that it was upon the 22nd of September; can you tell the bulk of water that was diluting it at that point?—On the 14th it was diluted by eight times its bulk, and upon the 22nd by 14 times its bulk of other water, and upon the 30th by 30 times its own bulk of water.

9249. All that, I believe, appears in your diagrams?—Yes; and the same thing is shown by the tables which Mr. Latham and Mr. Mansergh put in.

9250. As you explained it yesterday, this only shows diagramatically what was shown by the tables of Mr. Baldwin Latham and Mr. Mansergh?—Yes, that is so.

9251. Now, taking Greenhithe upon the 14th?—The sewage was there about 10 days old.

9252. And how much was it diluted?—It was diluted by rather more than 14 times its bulk of water.

9253. Upon the 22nd by rather less?—Yes, by rather less than 14 times its bulk.

9254. And upon the 30th of November?—Upon the 30th of November, during that great flood, the sewage passed Greenhithe about three days old, and was diluted by 45 times its bulk of water.

9255. Take the same with regard to Gravesend?—In September it passed Gravesend about 16 or 17 days old, and was diluted upon the 14th by about 21 times, and upon the 22nd by about 16 times its own bulk of other water.

9256. We find upon the 30th that it was some five or six days old when it passed Gravesend?—It was five or six days old when it passed Gravesend, and it was largely diluted by 63 times its bulk of water.

9257. Now will you just give me the same figures from your notes as regards Southend?—At Southend in September the sewage was from 30 to 32 days old, and was diluted on the 14th by 184 times and on the 22nd by 149 times its own bulk of other water. On November 30th, at the same place, the sewage was about $11\frac{3}{4}$ days old, and was diluted by about 305 times its own bulk of other water, always showing the great effect of the increased volume of water.

*Mr. R. W. P. Birch, M. Inst. C.E.*

14 Feb. 1883.

9258. You told the Commission that all these deductions depend upon the chlorine test?—Yes, they depend upon the chlorine or salt tests.

9259. It was suggested by my learned friend, Mr. Bidder, in his cross-examination, I think it was, of Mr. Mansergh, that in estimating the chlorine we had taken the wrong figure; that it ought to be 20 parts in 100,000 instead of 10, which our witnesses had taken it at, in sewage; have you calculated what difference it would make in your calculations of the 20 parts which Mr. Bidder stated had been taken instead of the 10 grains?—It would make absolutely none.

9260. Will you show how that is?—If we had increased the quantity of chlorine in the sewage from 10 to 20 parts in 100,000 parts we should have increased the chlorine in the upland water by 1 part in 100,000 parts; and if we had increased the quantity of chlorine in the upland water by 1 part in 100,000 parts we should have affected the size of the column at any particular place; that is to say, the proportion of fresh water to salt, by $\frac{1}{1959}$th part, which is about $\frac{1}{20}$th per cent.

9261. Supposing the 20 parts had been taken instead of the 10, have you worked out how much difference in the time it would have made between the sewage being poured in at Barking and reaching at Southend?—One part in 1950 means a difference of about 20 minutes a month; so that the analysis of the sewage, whether correct or incorrect, makes but 20 minutes difference in the period taken to travel from Barking to Southend.

9262. So that it is not a very serious matter if it only makes a difference of 20 minutes in a month?—No.

9263. There was a suggestion that the Medway water came up the river, and vitiated the results which are got from the chlorine tests. My learned friend Mr. Bidder made that suggestion yesterday. What do you say to that?—I do not think he could have been in earnest, because we find that about a fiftieth part of the sea water at Southend comes up to Barking. We also find that in order to get that quantity of sea water up there, the sea water at Southend must be 20 times as great as the Thames water at Southend. In order to drive the Medway water up in that proportion, which, as I will show you directly, is remarkably small, and does not affect the column at all, we should have to make the Medway, which is only a tenth part of the Thames, 20 times as big as the Thames; and then we should have to give it the property which sea water only has of a much greater specific gravity, which is the only force which drives the salt water up the river.

9264. (*Sir John Coode.*) You mean, I suppose, to say that the effect of the tide is to drive the fresh water of the Medway back up the channel of the Medway, and not up the Thames?—No, that is not what I mean.

9265. Will you kindly explain what you mean? You say that the Medway water does not come up the Thames?—No, not appreciably.

9266. Will you explain how you show that?—We know that in the Thames at Barking there is a quantity of water which did not come down the Thames, which must have come from seawards, equal to a 50th part of the sea water at Southend. Now, it follows from that, that only a 50th part of the sea water at Southend can get up to Barking. Now, it is suggested on the other side that the Medway water gets up to Barking. Only a 50th part of the sea water at Southend can get up to Barking, and a 50th part of the whole Medway would be only a 500th part of the Thames; so that, supposing the circumstances were most favourable, we could only get a quantity of Medway water at Barking equal to a 500th part of the river water at Barking, and we do not profess that our calculations are nearer than a 500th. There may be an error of a 500th, and I should be very pleased if there were no greater error.

9267. You said that what brought the sea water up was its greater specific gravity?—Quite so.

9268. Therefore there would be no tendency for the fresh water of the Medway, which is of less specific gravity, to come up at all?—No, not at all; the tendency would be for the water of the Medway to go out just as the water of the Thames does; to scramble, as it were, for a place to get out.

9269. (*Mr. Abernethy.*) The water at the mouth of the Thames is almost entirely sea water?—Yes.

9270. And the sea water being of greater specific gravity would not permit the fresh water of the Medway to find its way up the Thames, the tendency would be for the water of the sea to displace the fresh water?—Yes, quite so; there must be just as great a tendency for the Medway water to get out of the river as for the Thames water to get out.

9271. (*Chairman.*) As I understand, when river water runs into the sea it becomes a mixture of two waters?—Yes.

9272. And it is that mixture which runs up the river?—Yes.

(*Dr. Stevenson.*) You say that the salt water has a greater tendency to run up than the fresh water. I do not follow that.

9273. (*Sir John Coode.*) Is it not rather the rise of the tidal column which causes the water to run up the Thames than the greater specific gravity?—If it were only for the rise of the tide, the fresh water would be dammed back by the salt water. What makes the sea water penetrate the fresh water is the greater specific gravity of the sea water.

9274. It may make it penetrate it, but it is the rise of the tidal column which drives it up?—Certainly, which drives it up; but the thing which makes the two things mix is the greater specific gravity.

9275. (*Mr. Abernethy.*) Supposing this is the Medway and this is the Thames (*drawing a diagram*), both flowing into the sea at a common point, a very small portion of the water from the Medway is mingled with the sea water at that point?—Yes.

9276. The flood tide comes from the North Sea, does it not?—I suppose it does.

9277. The tidal column rises and the tidal column is entirely sea water; how can any fresh water passing from the Medway displace the column of tidal water passing up the Thames?—I do not quite grasp the point of your question.

9278. No fresh water from the Medway can displace the tidal volume of water which is flowing up the Thames?—It would mix in a small quantity; but only a very small proportion of the water at Southend can get up. We have shown that a 50th part of the salt water at Southend gets up to Barking; therefore if only a 50th part of the Medway water did get up, it would be perfectly ridiculous in a river 10 times as big as the Medway.

9279. (*Mr. Balfour Browne.*) Supposing the fresh and the salt water were of exactly the same specific gravity, would the effect of the tidal column coming in be simply to raise the fresh water as against the salt?—Yes.

9280. But the fact being that the heavier tidal water coming in raises the fresh water, there is therefore, through the greater specific gravity of the salt water, a diffusion of the salt water through the fresh?—Yes, quite so.

9281. This diagram of yours shows how the fresh water is got rid of at the mouth of the Thames?—Yes.

9282. This diagram is true of the Thames, and the same is also true of the Medway?—Yes, perfectly.

9283. When the fresh water comes down the Medway it is disposed of by the sea exactly as the fresh water coming down the Thames is disposed of; am I right in that?—Yes; but even if the whole of the Medway water presented itself right in the centre of the Thames, then only a 50th part of the Medway water could go up the Thames; and a 50th part of the Medway water in a river 10 times as big as the Medway must only make a difference of a 500th part, which is quite inappreciable in our calculations. I should mention that of course this difference of specific

gravity acts quite as strongly upon the Medway water to take it out into the German Ocean as it does upon the Thames water.

9284. Have you built any argument upon the salt survey with regard to the sewage pollution above Barking?—No. I have applied this salt process simply to the river between Barking and Southend; but there can be no doubt that with every flood tide the sewage discharged upon the last of the ebb must go up very nearly the whole range of the tide; it must go up 11 or 12 miles.

9285. Being discharged upon the last of the ebb, it therefore is carried up upon the first of the flood?—Yes, leaving a streak of sewage behind it from 12 miles above the outfall down to the outfall.

9286. While you were on the river, was the water at all favourable to the development of any nuisance from the sewage?—No, certainly not; from the middle of September to the early part of November it was cold, and we should not have perceived the nuisance that people complained of in summer.

9287. But having been from six to eight weeks upon the river, I daresay you can tell the Commission what was the appearance of the surface of the river even when you were on the river?—It must be very striking I think, to anybody who is constantly passing up and down the river; that is to say, the floating sewage. I have drifted up in a steamer amongst the sewage and seen the most undisguised sewage upon the surface up as high as Blackwall, and down the river certainly as low as Purfleet, pretty nearly every day, either floating in the currents or lying on the side marking the distinction between the slack places and the stream.

9288. In standing below the paddle-box, could you distinguish the sewage in the river from the spray?—I was reminded of the sewage more in that way than in any other way. Standing on the sponsons of the tug, the spray from the water would come in your face, and you would be then reminded of the sewage most distinctly. I have noticed that as far down as Erith on more than one occasion.

9289. Now, with regard to the temperature, I think you have something to say; I think there were temperature tables made by Dr. Collingridge?—I know they were generally low. I do not know how high they were, but they were considerably below the summer temperature.

9290. And that would to some extent account for the river not being a nuisance at the time that you were upon the river?—Certainly.

9291. Do you remember the 22nd of October?—Yes.

9292. Were you on the river on that day?—Yes, I was. I had occasion to go up Deptford Creek; it was after a considerable amount of rain. I went up Deptford Creek, and there I found that no doubt the storm overflows were at work, and I saw more solid sewage floating upon the surface of the water than I ever saw floating on the surface of any water in my life before.

9293. That was discharged from the storm overflows?—Yes.

9294. (*Chairman.*) That was at Deptford Creek?—Yes. I think that must be a serious disadvantage to people having property in the Creek.

9295. When you say sewage, do you mean to say that it was the excreta of people?—Yes.

9296. (*Colonel Ewart.*) Was it in large quantities?—Yes; it was apparently the strongest matter in the form of sewage that I have ever seen.

9297. (*Chairman.*) What was the tide running then?—I cannot say, but I can give you the time; it was a quarter to 12 upon the 22nd of October.

9298. That is when you were there?—Yes. On reference to the tide tables, it appears to have been about half ebb.

9299. (*Colonel Ewart.*) Which side was it coming from?—It was in the middle of the stream in Deptford Creek. I cannot say which side of the creek it came from.

9300. (*Mr. Abernethy.*) Your diagram is based upon the supposition that all the sewage passes from Barking downwards to the sea?—Yes, so it does.

9301. That is the basis of your calculation, is it not, that all the sewage discharged at Crossness and Barking passes downwards to the sea?—Yes.

9302. And there it is all held in solution?—The calculation does not depend upon that. When I talk about sewage, I mean simply the water which has passed through the London sewers. I have not gone into the question of how that is altered. Any water that has gone through the London sewers I call sewage.

9303. (*Mr. Balfour Browne.*) We rather are dealing with the column of fluid throughout?—Yes, certainly.

9304. This diagram does not depend at all upon any solid matter at the bottom of the Thames, but only deals with the column of water coming from the sewers?—Certainly. The only thing that bears upon the deposit at all is, as I said, that the flood tide was stronger than the ebb tide.

9305. You told us yesterday that the flood was stronger than the ebb, and that that would have the effect of sweeping it up the river, and unless the scour were considerable that would not have the effect of floating it out upon the ebb?—Quite so.

9306. I want you to point out to me Deptford Creek upon the map. (*The same was pointed out.*)

9307. That is where the storm overflow of the Metropolitan Board of Works comes in?—Yes. I did not go up to the outfall. I only saw the sewage; I was about 100 yards from the creek's mouth.

9308. (*Chairman.*) This was floating sewage, was it?—It was floating out of the creek with the stream.

9309. (*Sir John Coode.*) But from the storm overflows?—I presume so.

9310. (*Chairman.*) You do not mean that it was from the regular discharge of the sewers?—Not at all. I did not see it come from the storm overflows, but I am convinced that it did come out from the storm overflows.

Cross-examined by Mr. Michael.

9311. Did you see sewage coming down from the storm overflows at any other period except the one you have mentioned?—I was not much in that part of the river where the storm overflows were.

9312. That was the only time you saw it?—I was not in that part of the river where the storm overflows were. I was below bridge a long way.

9313. You were asked about the chlorine tests, whether you had merely taken the matter in solution, and passed over the matter in suspension?—Yes.

9314. Chloride of sodium is a soluble matter, and if there were any chloride of sodium in the suspended matter, that would be dissolved out and washed down by the tide?—Yes, I suppose so.

9315. Taking your period of the 14th of September, the sewage, I understand you to say, was 17 days in the reach of water between the outfall and Gravesend?—No, that is not so.

9316. Take your own time, and let me know if you can make out the time in which any gallon of sewage turned out from the outfall, say upon the 14th of September, would reach Southend?—I cannot deal with that. Take one put out at Barking upon the 16th of August, that reaches Southend upon the 14th of September.

9317. How many days is that?—30 days.

9318. Take a gallon of the sewage and tell the Commission through how many miles that gallon of sewage would have travelled in the water during that period?—You mean how many miles it would have been shaken backwards and forwards.

9319. How many miles would it have travelled in that period?—30 times 50.

*Mr. R. W. P. Birch, M. Inst. C.E.*

14 Feb. 1883.

9320. That would be 1500 miles according to my arithmetic; but that would have to be doubled?—Take 12½ miles each ebb and each flow, and there would be two tides each way in a day.

9321. It is 50 miles to Southend?—It would be shaken backwards and forwards, no doubt, and mixed, and whatever advantage you can get out of the mixing would have taken place.

9322. Take a gallon of sewage which had traversed 1500 miles of running water, what would it be at the end of that period?—I do not think you can take it in that way.

9323. But I want to take it in that way. A gallon of sewage sent out from an outfall into a running river and travelling 1500 miles, what would the condition of that be *qua* sewage at the end of that period?—I do not know the least in the world.

9324. But you have constantly given your attention to matters of drainage involving questions of this description?—If the people at Southend asked me if I thought that sewage having travelled that distance would harm them I should say I did not think it would.

9325. Long before that period, would it not have ceased to be anything but water; would there be any appreciable pollution in sewage that had travelled, I would not say 1500 miles in running water, but 150 miles?—I am not really an authority upon the matter, and would prefer not to answer the question.

9326. I understood you to say to the Commission that it made no difference to your chloride of sodium calculations whether there were 10 or 20 grains of chlorine, as far as purposes of calculations were concerned, in the sewage; is that so?—Yes.

9327. Are you aware that chloride of sodium is taken as the test of the amount of pollution in sewage?—My calculations do not refer to pollution.

9328. Answer the question first, and explain afterwards. Are you aware that chloride of sodium found by a chemist in sewage is one of the tests he applies as to its polluting character?—Yes, in pure water, no doubt.

9329. In any water?—No; you cannot tell anything about sewage in sea-water from the chlorine.

9330. Supposing a sample of water is given to a chemist, and he finds 20 grains of chloride of sodium in one sample, and 10 in the other, would not the chemist say that there was double the quantity of polluting material in the one as compared with the other?—Yes, I suppose he would, in pure water.

9331. In any water?—No; any sea water would upset that at once.

9332. Taking any two samples, and supposing that it is a question of pollution or non-pollution of water, and a chemist finds in one 10 grains of chlorine, and in the other 20 grains of chlorine, are you aware what the respective proportions of pollution would be in the two samples?—I do not understand chemical analysis the least in the world. I take it that the quantity of chlorine gives us the proportion of salt in the sample, and that is quite enough for this purpose.

9333. It makes no difference, whether you assume, as the basis of your calculation, that sewage contains 10 parts or 20 parts of chlorine?—I told you how much difference it did make for these calculations, namely, about one-half per mil.

9334. If sewage contained double the strength in one case that it did in the other, it would make no more than that minute difference in your calculations?—As far as progress is concerned.

9335. As far as anything is concerned?—No; I have not dealt with the burning up at all.

9336. Do you doubt that from the very first moment the sewage passes into fresh water it undergoes decomposition?—I do not doubt that, but I do not know anything about the degree.

9337. Do I understand that your tables merely put in a diagrammatic form the figures which have been given us by Mr. Mansergh and Mr. Latham?—Not exactly. These diagrams are based upon the actual quantity of rain-water which comes into the river on every day. Mr. Mansergh and Mr. Latham, as I said yesterday, have much greater experience than I have, and they have arrived by an average and a few figures at very nearly the same figure as I have arrived at by going into it in great detail.

9338. What is the principle they have taken in estimating the quantity of upland water with respect to the quantity coming over Teddington Weir?—They have taken all the tributaries.

9339. In taking the quantity of fresh or upland water coming into the River Thames upon the 14th of September, what water did they take as passing over Teddington Weir; was it the water of that particular day?—I do not know at all; I believe it was.

9340. What have you taken?—I have taken as near as I could the quantity of water which reached these particular places upon these particular days.

9341. Is that the same thing?—No; but it would make no difference at all (and I will tell you why) in arriving at the column. The great problem is to arrive at the size of the column, and any little error in the quantity of fresh water would only make an error of the same kind as the difference between 10 and 20 parts of chlorine makes in the analysis of the water.

9342. Supposing that there had been for 10 days what I will call an ascending cone of 100,000,000 cubic feet upon the 1st of September, and increasing until it comes to 200,000,000 upon the 10th of that month, and then a descending cone of 200,000,000 going down again to 100,000,000 cubic feet coming down over Teddington Weir upon the 20th; will you explain to me what they would have done, and what you would do?—They have first of all arrived at the column of fresh water as I have done, as shown by the white streak in the centre of the blue. Then assuming the water for the last month were the same as we find to-day, I think they say, it will be 34 or 35 days. I, on the other hand, say that it is not near enough; we shall have Mr. Michael or Mr. Bidder asking us about it. I will take the trouble to go into it and see what the actual flow was, and instead of taking the number of days due to the flow of the day, I have taken the number of days due to the flow of the past 30 days, and of course the number of days varies inversely as the flow. My flow, in some cases, was larger than their flow, and where it was larger I make the number of days smaller, and where my flow was smaller than their flow I make the number of days larger.

9343. Did you hear what Mr. Latham said, that if 200,000,000 was passing over Teddington Weir, it was an impulse communicated immediately to where the fresh water impinged upon the salt; that is 200,000,000 impinging upon the salt water 12 days before you have calculated it; if there is a difference of two to one millions you have taken some means between the two?—If Mr. Latham puts in the double quantity, he is right in saying that a double quantity will come out at Southend.

9344. Upon the same day?—Yes, but not of fresh water; of salt water; that makes all the difference. Every million of water you put in at Teddington prevents a corresponding quantity of water coming in at Southend; that is what Mr. Latham meant, and what he said.

9345. Will you take the 14th of September 1882 in the First Division, and show the Commission the mode you have adopted in order to test the quantity which Mr. Mansergh gives for the same day. I ought to say that yours is an intermediate period between high and low water; is not that so?—Yes, certainly.

9346. And Mr. Mansergh's is in one case high water and in the other low water?—Yes.

9347. The mean between the two will therefore make it correspond with yours?—Yes.

9348. Just work out one single division, and show whether or no a corresponding result has been obtained by you to the figures given by Mr. Mansergh; take

the first division below Crossness?—Take the sewage of the 16th of August.

9349. Would you begin by working out the Crossness division to correspond with Mr. Mansergh's of the same day, in order to see whether the results obtained by you are the same. I will only trouble you with one. We must take a fifth, in the first place, of 171,800,000, must we not? Taking Mr. Mansergh's table, upon the 14th of September 1882, at absolute high water, Division 7, "Quantity of upland water and sewage in each division"; the first division below Crossness I am going to take as the test. The figure is 1,112,518,704; then, if we turn to the next, which is low water, it is 798,899,651, adding those together, and dividing them by 2, will give you your mean quantity, or ought to?—That is, the mean between 800,000,000 and 1,100,000,000, which is, roughly speaking, 950,000,000.

9350. Would you kindly work out your own division, and see whether I have adopted the right plan in doing so. I would ask his Lordship to turn to the witness's diagram.

(*Mr. Lumley Smith.*) That would give you a mean of five miles; is the witness's five miles?

(*Mr. Michael.*) Yes. I am going to make them correspond to the five miles below Crossness; that is what you have taken from Mr. Mansergh, and I am going to take five miles from you. I take a fifth of your division, which represents the first division below Crossness, which comes to 171,800,000.

(*The witness scaled upon the plan.*)

9351. First take a fifth of your 171,800,000, then take your 164,964,940, then your 177,517,622, and your next four divisions, and then a fifth of your 161,455,422?—I make it something under 900,000,000; what do you make it?

(*Mr. Michael.*) 843,000,000 in round numbers.

(*Chairman.*) Do you correspond?

(*Mr. Michael.*) No; I make it that there is about 100,000,000 difference between us.

(*Mr. Lumley Smith.*) A little difference will arise from the same high water not having been taken. The witness's high water has been taken from a synchronous line, and Mr. Mansergh's has been taken from the absolute high water.

9352. (*Mr. Michael.*) Let me make it quite clear. To make the divisions correspond take one fifth of your 171,800,000, which is equal to 34,360,000; then your next division, 164,964,940; then the next, 177,517,622; then the next, 140,358,034; then the next, also 140,358,034; the next, 153,965,806; and then one fifth of the next division of 161,455,422, which is equal to 32,291,084, making a total, as against 955,000,000, of 843,815,520?—I should mention to you that it is very likely you have hit upon a division which has not been calculated, because every one of the daily divisions has not been calculated.

(*Chairman.*) As I catch it there is a difference of between 11 and 12 per cent.

(*Mr. Michael.*) Yes, of 12½ per cent.

(*Witness.*) But there is another very good reason for a discrepancy between us in these upper reaches of the river. Although the total column and the total number of days is exactly right there may be a considerable discrepancy between Mr. Mansergh, Mr. Latham, and myself at the Barking end for this reason: we are dealing with a column, and the whole of these calculations are based upon the measurement of a column; therefore it was necessary to take the dimensions of the column synchronously at the different points, and we have taken the dimensions of that column at high water at Southend, and at low water at Southend, and that would be half an hour before high water and low water at Erith, and more than that before high water and low water at Barking.

9353. (*Mr. Michael.*) How much difference do you say the difference between synchronous and absolute high water would make; would it make more than 1 per cent.?—I should think that is probably the error, because the whole thing is exactly the same.

9354. I will not allow that to stand in the way. I will take the fifth, making 803,000,000 against 965,000,000, or a difference of 160,000,000; however, I have sufficiently directed your attention to that?—It is very probable that the same points have not been taken at Crossness.

(*Sir Benson Maxwell.*) Was not the difference between the two in the last case in the other direction?

(*Mr. Michael.*) No, it is the same; in the first division it was 843 against 955, and in the next division it was 803 against 965.

(*Witness.*) But that is a discrepancy between what has been arrived at in an off-hand way and what has been arrived at by going into the matter in the fullest details.

(*Sir Benson Maxwell.*) Do I understand you to say that the difference of 20 per cent. between Mr. Mansergh's figures and yours makes no appreciable difference in the calculation?

(*Chairman to Mr. Michael.*) Suppose we take them to be wrong to the extent to which you wish to make them wrong, what effect would it have upon our judgment afterwards?

(*Mr. Michael.*) I cannot tell what effect the whole of these chlorine determinations may have upon your judgment.

(*Chairman.*) The whole of the evidence which has been given hitherto by the scientific witnesses is for the purpose of showing what will be or ought to be the condition of the river according to their speculations. They may be considerably wrong; they may be wrong 25 per cent., either one way or the other; but then in addition to that we shall have to consider the evidence which has been given by people who say that you can see it and smell it, and, if you please, taste it and touch it; that it is evident to all the senses. Then when you put those two things together, supposing that were made out, would it matter that some of these gentlemen are wrong 10 or 12 per cent. in their speculations as to what ought to be the state of things?

(*Mr. Michael.*) I imagine it would, unless you are going to judge by the evidence of non-scientific persons as to the effect of sewage being poured into water.

(*Chairman.*) If you were going to drink a glass of the water, it might perhaps make a difference whether it was 1 per mil or 1½ per mil.

(*Mr. Michael.*) It is a very important matter when you come to consider that sewage is directed by Act of Parliament to be poured into the river, whether it is poured directly into the water and remains there, and other local circumstances.

(*Witness.*) Another difference between Mr. Mansergh and myself is that I have interpolated the proportions absolutely in a descending line from the percentage at Southend to the percentage at the next point. Mr. Mansergh has done it in blocks, so that one of his blocks may be a little bit more than I make it, and the other a little bit less; by taking out isolated blocks you may find one a little more and one a little less, but the total column agrees within 1 per cent.

(*Mr. Michael.*) Do not say that, because I can give you the totals if you prefer. I cannot ask the Committee to give the time to go through the whole of the calculations, because they have already taken a very long time, but I venture to put it to you that there is a difference very much larger than that, that there is a difference of 10 per cent. between the totals at which we have arrived.

(*Sir John Coode.*) Between which points?

9355. (*Mr. Michael.*) Between Barking and Southend. I have worked out the quantity of upland water and the proportion of sewage to upland water. I say that there is a difference of 10 per cent. between the results arrived at by the two modes adopted?—I should like to go into this matter, for I think it is capable of explanation.

(*Chairman.*) It would be better if it would take you any time to work out the answer to Mr. Michael's

*Mr. R. W. P. Birch, M.Inst. C.E.*

14 Feb. 1883.

question, and he would be content if you would come another time and answer it.

*Mr. Michael* agreed to the suggestion.

(*Mr. Lumley Smith.*) If my learned friend has the calculation, I do not know whether he would let the witness have it and see whether it is correct.

9356. (*Mr. Michael.*) They are merely addition sums which the witness has to do of the totals arrived at by Mr. Mansergh and himself; it is simply the addition of the columns of figures and the deduction of the percentage. (*To the witness.*) Now, would you kindly tell me when you commenced to be in the steamboat "Toby" on the river?—In the middle of September.

9357. And you remained on board that boat for about two months, did you not?—Yes.

9358. Day and night?—Yes.

9359. In all parts of the river?—In all parts of the river below London.

9360. What are the points between which you ranged?—We could not go under the bridges.

9361. Then you had the general supervision, as I understand, of the men employed about the floats?—I had.

9362. I want to ask you one or two questions; I shall be as short as I can. Who was in charge of the floats on October 16th?—I should think I probably was.

9363. I will give you exactly the one float I want to know; the one that was driving up Erith Reach upon the 16th October. Could you tell me the name of the person who was in charge of the float at 1 p.m.?—Do you mean the waterman's name?

9364. Yes?—I can ascertain it.

9365. On October 17th you had two men called Meares and Whiting?—Probably. I know those names.

9366. Were they in charge of the float at Charlton at 6.15 in the morning?—I do not know offhand, but I will have it ascertained.

9367. I will go over the times at which we want the information, and you can give us the particulars afterwards. On October 16th, I want to know who were in charge of Float No. 6; they were near Millwall Pier. On October 29th had you two men called Tanner and Long at 5.50 a.m. On October 30th had you two men named Taylor and Clements employed at 5.17 a.m.?—I know those names. I do not know whether they were on duty or not; if you will give me the charges, I will have them answered.

The *Chairman* suggested that a list should be made out and supplied to the witness.

9368. (*Mr. Michael to the witness.*) Will you kindly give me the points at which the chlorine determinations were made, and the times?—I cannot speak from my own knowledge about this matter, but someone is coming who will be able to tell you. I take it that they were taken at St. Paul's Pier, Deptford, Barking, Crossness, Erith, Gravesend, and Southend, at high and low water.

9369. At what dates?—The 14th and 22nd of September and on the 30th of November.

9370. The chlorine determinations were taken upon three occasions at those various places?—Yes.

9371. (*Sir Benson Maxwell.*) Did you see them taken?—No, I have used the information which was sent to me.

9372. Do you know of your own knowledge what part of the stream they were taken at; were they in mid-stream?—I understand that each sample was composed of numerous samples taken at various places across the stream at various depths.

9373. (*Mr. Lumley Smith.*) We have it in Mr. Latham's evidence that the chlorine samples were taken by taking samples of the water at different places across the river and mixing them up.

(*Sir Benson Maxwell.*) That was stated by a person who had only a general knowledge of the matter, and not a personal knowledge. Mr. Latham had the general supervision, and it was reported to him that they were so taken.

(*Mr. Michael.*) I was under the impression that Mr. Birch had the general supervision.

(*Witness.*) In using them, I have taken them as mean samples of the water of the whole of the cross section of the river.

(*Mr. Lumley Smith.*) We shall be able to tell you where the specimens were taken for the purpose of the tests.

(*Sir John Coode.*) When, where, and how?

(*Mr. Lumley Smith.*) As Mr. Birch is coming back again, I venture to think it might be advisable to postpone his re-examination entirely.

The witness withdrew.

Professor William Cawthorne Unwin examined.

*Prof. W. C. Unwin.*

9373. (*Mr. Lumley Smith.*) You are a member of the Institution of Civil Engineers?—I am.

9374. And you are Professor of Hydraulic and Mechanical Engineering at the Royal Indian Engineering College at Cooper's Hill?—I am.

9375. I wish to ask you a few questions upon the subject matter of our inquiry. First of all upon your opinion as to how far the movement of sewage in the river is a question of hydraulics. The sewage, as we know, gets into the river first of all—that we may take for granted—it gets from the sewers and the outfalls into the river; does it all remain there, or are there any influences at work which would get rid of some or any of it. I will ask you that before we come to consider the question of hydraulics, where it will get to?—There seems to me to be only two ways in which the volume of sewage discharged into the river can disappear from the river, and so escape, being considered a matter of hydraulics. The sewage may decompose into gas which escapes into the air, but I think the volume which escapes in that way must be very small. Part of the sewage may be deposited upon the bed of the river, and that no longer forms part of the flow of the river; but there are no means of ascertaining what proportion of the sewage disappears in that way, only I suppose it is then still in the river, and still liable to do injury to the river.

9376. If I may stop you for a moment, a portion may pass out in the form of gas into the air; that, you think, would not be a matter of much importance as it would not be a large amount?—So I think.

9377. A portion would go to the bottom of the river—that is a matter of hydraulics—there is no means of ascertaining what it is?—I know no means of ascertaining what it is.

9378. Then a portion would remain in the river, and you deal with that for the purpose of representing the sewage?—I do.

9379. Are you in a position to give any evidence with regard to the extent to which the sewage which remains in the river is noxious or innocuous?—I leave that question entirely to the chemists and biologists.

9380. For the purpose of your examination you treat the sewage which goes into the river as remaining in the river?—Yes.

9381. Now, going into the principles upon which the movement may be arrived at, we will deal with what would have been the case if this had been a non-tidal river. In the case of a non-tidal river what should we have to consider as the movement?—The principle we must have recourse to is that the quantity of water between two sections remains constant, so that, for any given period, the quantity which flows in at one end is equal to the quantity which flows out at the other.

9382. That is a very simple question; you take two cross sections of the river, and what flows in at one will flow out at the other, assuming that the

section is the same?—Yes, but there is this point to remember, that if the river is carrying different materials, such as river water, sea water, and sewage, then the quantity of each of those materials which flows in at one end must be equal to the quantity of each of those materials which flows out at the other.

9383. That is to say, if the quantity of each which goes in at one end is equal, there would be an equal quantity of each flowing out at the other?—Yes.

9384. Each keeps the same ratio?—Yes; that would have to be assumed in the calculation.

9385. Now, coming to the case of a tidal river, does that alter very much the condition of what passes out?—The volume between any two sections is constantly changing.

9386. What does it change with?—With the height of the tide; but if we neglect the alteration from day to day of the range of the tide, then at corresponding phases of the tide the volume between two sections is the same.

9387. Taking the same height upon different days, you always get the same quantity between two cross sections, that seems simple also, and that applies equally I presume, subject to anything that comes from mixing to the component parts of the fluid?—Quite so.

9388. Now will you proceed with regard to what takes place at each particular section of the river, taking the volume of the flow of the different sections of the river, and beginning at the uppermost end of the reach of the tide. Taking it at Teddington you get coming in the water over Teddington Weir?—At Teddington there flows in a volume of upland water, and on the principle that I have just stated the volume of flow in the period of a tide, across every section of the river, must be exactly equal to the volume of the upland water, with the exceptions which I have to make presently. The down stream displacement at every section of the river must therefore be, in each tide, the volume of the upland water divided by the area of the section.

9389. You know what comes in at Teddington, and that quantity must pass every section of the river. As you go down the river the same number of gallons as come over Teddington Weir will be displaced, of course, at any particular section of the river in the course of a day, whether the whole goes through or not, will depend on the size of the section, it will be affected by the size of the cross section?—The same volume flows across every section.

9390. Then it is the velocity that would vary?—The displacement will vary with the area of the section.

9391. Of course by displacement you do not mean the mere oscillation of the tide, but merely that the water is pushed further down the river?—The displacement due to the upland water alone.

9392. You said an exception would have to be made—is there any general cause which modifies what you have been saying?—In the oscillating flow of the tide there are generally local currents and other differential motions of different portions of the water; the effect of that is that some portions of the water are carried further up stream during the flow of the tide, than other portions. That resultant motion is not altered, because if one portion has gone further up stream, another portion must have gone less far up stream. During the ebb, some portions of water are carried down stream further than other portions. The resultant motion of the river is not altered, but when there are supplied to the river, different materials, at different points, this differential motion tends to distribute them in quite a different way from what they would be distributed in, if there were none of these local currents or differential motions.

9393. Take sea water for example; if the whole sea water came up *en masse* and kept altogether, it would go back again in the same way; but you say that in consequence of the currents and other local causes, some portions of the sea water would make a shoot and go further up the river than the general mass?—Yes.

9394. So in going down, portions of water so coming down shoot out beyond the main mass, and the consequence is that there is mixing going on over and above what would be expected but for these differential causes?—That is so.

9395. The result is, that you do find, or would be likely to find up the river, portions of what had come from below, further up the river than the main masses which have gone back?—Yes.

9396. Now will you apply that to the river above Crossness?—Taking the river above Crossness the water is fouler as we go down stream. Now, during the flow of any one tide, part of the foul Crossness water is carried up stream a distance greater than the mean tidal range and mixes with water which was previously at a higher point in the river.

9397. Putting that into simple language the mean tidal range takes up the water from below Crossness a certain distance, and portions of it are stirred up in eddies and mixed with the water above?—Yes.

9398. As the result of that, you have found foul water from below Crossness higher up than you otherwise would?—Quite so.

9399. Now take the case of the ebb; when the tide begins to ebb again what happens to that water which has been so carried up the river?—The water which has been carried up the river gets mixed with the whole volume of water in that part of the river where it is. During the ebb part of that goes down again, but part of the foul water is left behind mixed with the low water volume, so that at the end of the ebb there is a portion of foul Crossness water at a higher place in the stream than it originally was before the tide.

9400. Then after the first flow and ebb, a portion of the foul water has been displaced relatively to the rest of the water, so as to be higher up the river?—Yes, quite so; a portion of the Crossness water has gone up stream.

9401. Is that, according to the process you have been describing, likely or possible to be repeated in subsequent tides?—It must be repeated upon every tide.

9402. Then what would be the result upon the foul water?—The result is that, in the low water volume above Crossness, you have a portion of the Crossness water distributed in every portion of the river from Crossness up to Teddington. There is in the low water volume a portion of water which has come up from Crossness.

9403. (*Chairman.*) Will you allow me to ask you this—is this the result of observation or speculation upon the river?—I assume we know that in all rivers portions of the water move faster than other portions—assuming that, then what I have said must follow.

9404. Then it is the result of speculation?—Yes.

9405. If it were a perfectly straight cut like the Dee at Chester, I suppose your observation would not be true?—On the contrary, it would be quite true there.

9406. Would there be any eddy or current there?—In the straightest reach the central or surface portions move about 15 per cent. faster than the mean and about 25 per cent. faster than the bottom.

9407. Then that might make it applicable to the straightest possible navigable channel?—It is a principle applicable to all streams.

9408. (*Mr. Lumley Smith.*) Would that principle apply to a winding river like the Thames—would the local causes apply equally to, or in a greater degree than, where there was a straight cut?—It is a little difficult to say—probably you have more local currents in a winding river than in a straight reach.

9409. Then according to your theory in respect to this, the foul water from Crossness might work up the river to what points?—Either to Teddington or to a point not more distant from Teddington than the upland water displacement in the period of a tide.

9410. Close up to Teddington the upland water

*Prof. W. C. Unwin.*

14 Feb. 1883.

would drive it back and prevent it getting up?—Yes.

9411. Does the same principle apply to the pure water going down stream?—In the part of the river below Crossness, the effect of the mixing action is to make the Crossness water go down stream quicker than it otherwise would—the portion of the Crossness water which so goes down stream is balanced by the portion of sea water which comes up to Crossness.

9412. I suppose upon the same principle with the water below Crossness, which is what we will call four water, when any foul water gets higher up than the mean, a certain quantity of pure water must go lower down than the mean in order to fill its place?—Yes, quite so.

9413. So that the quantity is the same, but does the alteration of the pace of travelling or displacement of the water have any effect?—In a river entirely of fresh water it would have no practical effect, in a river consisting of different materials it has the effect of distributing all those materials over the whole length of the river.

9414. Then the practical result is that the distribution goes on over the whole of the river, and it is not confined to what would go on below Crossness?—Below Crossness sea water travels up stream, and the Crossness water travels down stream.

9415. What is the effect then of this mixing on the escape of the foul water from Crossness? You have told us that some of the Crossness water would go up stream, does the mixing make the foul water go to the sea faster or less fast than it would?—Below Crossness the foul water gets down to the sea much faster than it would if there were none of this mixing.

9416. Take the case of the tide coming into the river at Southend, have you taken any figures as representing what comes into the river at Southend during the flow of a spring tide?—During the flow of a spring tide something like 24,400,000,000 cubic feet of sea water flow into the river.

9417. And that, as I suppose, goes out with the ebb?—It mingles with some of the foul water up stream and carries back part of it to the sea.

9418. It takes up some sewage and I suppose leaves sea water behind?—It leaves some sea water behind.

9419. Taking another hypothetical case which I think my learned friend Mr. Bidder suggested, of an estuary; supposing the Thames had no supply of upland water, what would be the effect upon the sewage at Crossness?—If the Thames were an arm of the sea and had no supply of upland water, then, apart from the mixing action, it would gradually fill up with the sewage; but, in consequence of the mixing action, the sewage would still travel out to sea at a pace quite considerable. I could not say in what proportion to its present pace, but it would still travel out to sea, a portion of the sewage being taken out to sea in every tide, mingled with the tidal water, and a portion of the sea water which had come up, being left behind in the low water volume.

9420. By degrees the sewage mixed with the water in the estuary would get out to sea as in summer?—Yes, that is so.

9421. With regard to the actual condition of the river, that, as I understand from you, is affected by this mixing action which goes on between the tidal water and the low water volume, which we may take as coming from the upland?—Yes.

9422. (*Chairman.*) I suppose on account of the influences you have spoken of where sea water has got to a higher point than where it started from, the mixture might go up to the very top of the estuary?—It must go up to the tidal limit, except the distance occupied by the quantity of upland water that comes in during one ebb.

9423. I was supposing there was none, that was the case you put?—Then it must go right to the top.

9424. There would be a mixing right to the top, you think?—Yes, there would be a mixing right to the top.

9425. Even if it were a narrow estuary, if one can make use of such an expression, the effect would still be the same?—I say it must go to the top. I am not speaking of the quantity, the curve may be asymptotic, it may become excessively small.

9426. (*Mr. Lumley Smith.*) Of course the extent to which sewage comes up the river is a matter of degree according to your theory, the extent to which it would come up the river would depend partly upon the position of the outfalls and matters of that kind?—Quite so.

9427. We are aware that the legislature have said that the drainage of London shall be carried so far as not to come within the metropolitan area, you are aware of that?—I see it is stated very strongly in the debates in Parliament.

9428. It is stated also, I think, in the Act of Parliament; you have some references, I think, with regard to what the objects were, will you tell us very shortly what they were in the first place? I think the amending Act threw the whole burden upon the Metropolitan Board of Works, leaving them a discretion as to what should be done?—I have before me a reference to the Parliamentary debate, it will, perhaps, be taken as admitted that it was assumed that sewage should not be permitted to flow back into the Metropolitan area.

(*Chairman.*) We must look at the Act itself.

(*Mr. Lumley Smith.*) But your Lordship would know that we may gather what that Act meant by what took place when the Act passed.

(*Chairman.*) I think you are right that if it was evidently intended that the sewage was not to come to a particular place and we were instructed that it did, we might receive that evidence, although the Act did not say in distinct terms that it should not, but the witness cannot tell us what took place in Parliament as an expert.

9429. (*Mr. Lumley Smith to the witness.*) You think, in point of fact, that with the outfalls where they are, theoretically the sewage comes back or would come back?—Part of the sewage flows back through the whole range of the metropolitan district.

9430. Now I will ask you another question which seems to lie upon the surface; would the theory apply equally although the outfalls had been further down the river?—It would still apply. I have calculated, and will give you directly what would happen if the sewage were discharged at Gravesend.

9431. (*Chairman.*) The witness gave a guarded answer, or rather you put a guarded question. Is there a sensible quantity of sewage in the river up as high as Chiswick?—That is very close to the tidal limit, it just disappears at Chiswick.

9432. We will take Vauxhall Bridge—I am going to show you the actual quantities directly.

(*Mr. Michael.*) I ought to state that I had intended to direct Mr. Birch's attention to the fact that Mr. Mansergh's table assumes in the second division 15 per cent. throughout, it is an assumption upon his part of that certain quantity constantly. I put these figures to Mr. Birch for the purpose when he calculates it out, of showing that the percentages are very different from the one which is here assumed.

(*Chairman.*) I should like to hear what Mr. Unwin has now to say upon this point.

9433. (*Mr. Lumley Smith.*) I do not see how that bears upon Professor Unwin's examination at the moment, but I dare say it does. (*To the witness.*) Now will you just tell us your process, you have prepared some diagrams and tables, have you not?—I have. (*A set of diagrams and 13 tables were handed in; see Appendix A E, 1 to 21.*)

9434. Will you explain to the Committee, as you can do it better than I can put it to you, the mode in which you proceeded?—Data have been supplied to me of three tides during which observations were taken.

9435. What are the dates of those?—September the 14th and 22nd, and November the 30th.

9436. On those days there were supplied to you

certain elements for consideration, just tell us what those were?—From Professor Way I have received chlorine analyses of the water at 10 stations on the river.

9437. I think we may as well catalogue those stations as we go along?—Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, Barking, Crossness, Erith, Gravesend, and Southend.

9438. You had from Professor Way chlorine analyses of the high water found at those places?—Yes, both high and low water. From Mr. Mansergh I had computed sections of the river at high water, and at low water.

9439. At what places?—The same places.

9440. Those are the sections of the river?—Yes, those are the sections of the river, those sections being computed for absolute high water.

9441. When you say absolute "high water" you mean absolute high water, and absolute low water too?—Absolute high water and absolute low water; that is at the high water and low water at each place. From Mr. Baldwin Latham I have received gaugings of the water coming past at Teddington, and the water coming into the river from the tributary streams.

9442. As I understand you have got the water that comes over Teddington Weir; you have got the sectional area at ten places on the river, and you have got the chlorine analyses at those ten places?—Yes.

9443. Now will you tell us what you proceeded to do?—First of all, I proceeded to find the length of the horizontal oscillation of the tidal current.

9444. How did you do that?—I have computed the volumes of water in the river above each of the sections at high and low water, and perhaps I can make it plainest if I refer to a specific case. I am going to refer to Table 2, the column of total volumes. On September the 14th there were 10,474 cubic feet above Saint Paul's Pier at high water; there was almost exactly the same quantity above North Woolwich at low water. I say that the horizontal oscillation of the tide at those places was from North Woolwich to St. Paul's Pier.

9445. You found as much water at low water at one place as at high at the other?—Yes, the volume which occupied the river above St. Paul's Pier at high water extended to North Woolwich at low water, that gives the horizontal oscillation of the tide. Now, proceeding on that principle I have drawn diagram No. 1, which gives the horizontal oscillation of the tide for two tides, a spring tide, and a neap tide.

9446. (*Chairman.*) I do not know whether the other side will agree to that. I do not see because there are 10,474 feet at St. Paul's Pier at high water, and 10,210 at North Woolwich at low water, how that shows the oscillation of the tide. It may do so for aught I know, but I do not see why it should?—The water which occupied the space of the river above St. Paul's Pier at high water would just fill the river down to North Woolwich at low water. Then the resultant oscillation of any particle would be that distance, for if some particles went more, others must have gone less. The mean motion must have been through that distance.

9447. (*Mr. Lumley Smith.*) Are you putting out of consideration any water coming over Teddington Weir at the time?—I am treating it as a tidal question alone for the moment; we are treating it as a matter of tidal oscillation.

9448. Would it not be better to say that if you find the quantity of water at low water at one place is the same at high water at another place, that would come to the same thing?—It would come to the same thing.

9449. (*Mr. Michael.*) Do I understand that the tables are calculated without the upland water, and that the diagram is calculated with the upland water?—No; they are calculated upon the same basis. I am going to consider the displacement due to the upland water separately; it is more convenient to separate the motion of the water in the river into two components. There is a down stream motion due to water coming in at Teddington, and there is the movement due to the influx and reflux of the tide.

9450. (*Mr. Lumley Smith.*) Therefore now you are taking the motion of the tide regardless of the water coming in over Teddington Weir?—That is so.

9451. Will you now proceed with your explanation?—I have plotted the volumes in curves, and the horizontal intercept between the volume curves for high and low water shows the mean horizontal range of the tidal current. The horizontal intercept between the high water or the low water volume lines, shews the displacement due to the change of the tidal height. (*The witness explained his diagram to the Commission.*)

9452. (*Chairman.*) At low water at North Woolwich there was the same body of water as had been at high water at St. Paul's Pier?—Yes.

9453. Therefore it looks as if you supposed, though I know you do not suppose it, that the whole of the water at North Woolwich had gone away, and had its place supplied by what was formerly above Deptford, but that is not what you mean?—If you put a diaphragm across the river at North Woolwich at low tide, and allow the tide to shove that up the river, it would come at high tide to St. Paul's Pier, and you would have the same volume in the river above it, as you had down to North Woolwich at low water, without the diaphragm.

9454. (*Mr. Lumley Smith.*) You have taken the mean tidal oscillation?—Yes.

9455. There are corresponding curves for September the 14th and 22nd?—Yes, for the spring tide and the neap tide.

9456. The horizontal lines which are drawn between the high and low water curves represent the oscillation between the two places?—Yes.

9457. (*Chairman.*) Of course with regard to oscillation, you do not mean that if anything floating had been put in above Deptford pier at high water it would not have gone further down the river than North Woolwich in the course of a tide, do you?—If you exclude the action of the upland water for the present, then a floating body which had the mean motion of the water would go that distance; some floating bodies would go further, and some would go less, but the mean of the whole series would be that.

9458. What is the distance between the two places, not much more than four miles, is it?—I can now refer you to Table 3, where the horizontal oscillations are given in miles measured off the diagram.

9459. But the tide runs through it two or three miles an hour either way, does it not?—Yes, at the height of the tide, but it begins at nothing, and goes up to the maximum, and goes down to nothing again.

(*Mr. Lumley Smith.*) That is the tidal wave that runs up, but not the actual water.

(*Witness.*) At the maximum the velocity is perhaps three miles an hour, but the mean is very much less than that; it begins at nothing as I have said, and goes down to nothing again.

9460. (*Chairman.*) I thought we had had it proved before us that a thing will float up or down about 12 miles on a tide?—A float travels 12 miles, and therefore it appears that 12 miles is the range of the tidal oscillation; the only objection to that is that the floats are in the tideway and near the surface, and move a little faster than the mean motion. My tidal oscillation at the points where the floats were is a little short of 11 miles in a spring tide and 7 miles in a neap tide.

9461. (*Mr. Lumley Smith.*) That is shown in your Table 3?—Yes, in Table 3. I should like to put it shortly that the tidal ranges I got are shorter than those observed by Mr. Latham, the difference being due to the fact that Mr. Latham's floats gave the motion of the central and surface parts of the water, and not exactly the mean motion of the water.

*Prof. W. C. Unwin.*

14 Feb. 1883.

9462. Would this diagram be affected much by what you would call the disturbance owing to differential causes, eddies and so on?—It does not affect this diagram in the least, if it is understood to mean the mean of the motion of the particles, because for every lb. of water that is carried up stream by the mixing action a lb. of water is carried down stream by the mixing action, so the resultant is nothing.

9463. Now with regard to your Table 3, have you any further remarks to make?—Upon precisely the same principle I have calculated the horizontal displacement due to the variation of the tidal range from day to day. I found the amount of displacement due to the variation of the tidal range between the 14th of September and the 22nd of September, and I have given it in one of the columns of that table to compare with the tidal ranges; and it will be seen that the alteration of the height of the tide between those dates gives a considerable displacement, which is also shown by Mr. Latham's floats.

9464. I do not quite follow you as to why that shows horizontal displacement. I suppose that means displacement up and down the river?—From September the 14th to the 22nd the tides were decreasing from spring tides to neap tides, and during that time there was a displacement up stream by the number of feet given in that column, varying from 3,000 feet at Chiswick to 12,000 feet at Southend. When the tides again increased from neap to spring tides there would be a displacement down stream of the same amount.

9465. What are the feet in that column; they are horizontal feet, are they not?—Yes, they are horizontal feet. Supposing there had been no upland water the float would have been found, say at Barking, 9,000 feet upon the 22nd above where it was put in upon the 14th at the same stage of the tide.

9466. It is the horizontal feet opposite those places that you are referring to, is it not?—Yes.

9467. Is this horizontal displacement a displacement of the water?—The mean displacement of the particles of water at the section at the place which I named. For instance, the particles of the water at the North Woolwich section will be displaced up stream 9,300 feet between the 14th and 22nd by the alteration of the height of the tide; that is apart from any further action there would be of the upland water pushing them down.

9468. The next column gives the "increase of the low water volume"; what do you deduce from that?—That increase of low water volume is the increase of volume which has gone up stream and been left there in consequence of decreased range of tide That I put down to show that that is one of the causes that carries water up stream. As the tidal range diminishes a larger proportion of water is left behind in the low water volume.

9469. Now with reference to your first diagram; is that to scale?—The diagram is to scale, and the results measured from it are given in Table 3.

9470. Is there more than one scale on diagram 1?—The first half of the diagram is a vertical scale, 10 times as great as the latter half; the two scales are given on the diagram; the vertical scale is 10 times as great for the first half as for the second.

9471. (*Sir John Coode.*) These figures upon the horizontal lines represent, I suppose, distances in feet?—They do.

9472. (*Mr. Lumley Smith.*) You have finished with No. 1, now what is diagram No. 2?—I prepared diagram 2 in order to get a clear notion of the volume of upland water flowing in the river upon the three days for which I have made calculations. The ordinates of those lines are the volume of water flowing at each point along the length of the river; you begin with the volume flowing at Teddington, then there is a tributary, and you get a little more at Chiswick; above Deptford there is a tributary, then you get a little increase till you come to Barking, and there I have added in the sewage discharged, and at Crossness I have added the sewage discharged there, and so I have gone on.

9473. By fresh water you mean what is non-sea water, but includes sewage?—I mean the flow from Teddington, from the tributaries and from the sewers.

9474. When you get to Barking the first flow of sewage comes in?—Yes.

9475. Am I right in saying that this represents the comparative portion of the water at each part of the river which is not sea water?—Yes, the volume of fresh water, including sewage.

9476. It is not the amount of fresh water that is in the river, but of what comes in at each particular place?—Yes, the principal importance of the diagram is to show how very small an influence the tributaries have, except the two affluents at Crossness and Barking. At Crossness and Barking the flow is increased considerably.

9477. (*Sir John Coode.*) I should like to ask why the volume of sewage was so much less upon the 14th and 22nd of September, taking Barking more particularly, than upon the 30th of November?—There is a tributary there, which is added in as well as the sewage, and that tributary was flowing largely upon that day. I have taken the gaugings from Mr. Latham's tables. There are some tributaries which come in, the Lea especially, between Barking and Deptford.

9478. What strikes one is that the volume of sewage should not vary very much, but, if you take the 14th of September it is only one-half what it was upon the 30th of November?—I have taken the sewage at the same all round, but the difference is due to the flow of one of the tributaries.

9479. (*Mr. Michael.*) May I ask where you have put the River Lea?—I have taken all the tributaries, which enter between two sections, as entering at the lower of the sections.

9480. Where is the River Lea coming in?—The River Lea comes in between Deptford and Barking; it forms part of the step which you see at Barking.

9481. Or of the five miles above?—Yes, quite so.

9482. (*Sir John Coode.*) I understand the witness to say that at each step he allows for the tributaries which have come in since the last step?—I have formed the judgment that that was the most accurate way of dealing with it for my purposes. If the tributaries were very large, compared with the flow at Teddington, I should have preferred some other method, but as the tributaries are small, compared with the flow at Teddington, it is sufficiently accurate to take those which come in between any two sections as coming in at the lower section.

9483. (*Mr. Lumley Smith.*) I suppose it follows, does it not, that ordinarily when there is flood in those tributaries there is flood in the Thames?—Very much so; not always, but generally.

9484. The relative amount is not so very much altered?—No.

9485. Now Diagram 4 goes with Diagram 2, does it not?—I think I should prefer to take Diagram 3 next; Diagram 3 shows the amount of displacement down stream at each section due to the upland water alone; that is neglecting the tidal oscillation. By dividing the volumes in Diagram 2 by the areas of the sections, we get the displacement down stream, which has occurred in the tide, in consequence of the water which came in at Teddington and the other tributaries.

9486. (*Sir John Coode.*) That is what would have taken place if there had been no tidal water, or is that the actual displacement?—If you take two periods of low water the effect of the tidal oscillation has disappeared. There has been a flow of the tide and an ebb of the tide, and that has left things as they were. Between low water and next low water there will have been a displacement down stream, because during the 12 hours period, there has been a flow of water coming in at Teddington. The amount

of displacement due to the water which has come in is shown in the curves.

9487. (*Sir P. Benson-Maxwell.*) Is that the volume which has come in?—No, the volume which has come in divided by the area of the section; and this gives you the displacement down stream, which is due to the upland water alone. Diagram 3 is calculated for September the 14th, when the quantity of water at Teddington was about the average quantity. I have not drawn a similar diagram for other days, because it was simply to give an idea as to the way in which the displacement due to the upland water is diminished as you go down stream.

9488. (*Mr. Lumley Smith.*) Diagram 3 is in miles per tide?—Yes, miles per tide.

9489. Then, taking it to Gravesend, it goes down to the fifth of a mile?—Yes, 0·2 miles.

9490. Then at Gravesend upon any particular tide the displacement due to the upland water would be a fifth of a mile?—Yes, per tide.

9491. By "tide" do you mean a complete tide, up and down?—By a tide in all my calculations I mean 12½ hours, or, to take it more exactly, 12 hours and 25 minutes.

9492. Then at Gravesend it would be about ⅖ths of a mile a day?—Yes, ⅖ths of a mile a day almost exactly.

9493. And so on for the other places?—Yes.

9494. That is due to upland water only. Now have you anything more to say upon Diagram 3?—These are the displacements which a float should show if the float really had the mean motion of the water.

9495. (*Sir John Coode.*) That is to say, that if there were no wind or no disturbance due to eddies or abnormal causes, the theoretical motion?—That is the motion the float ought to have if it were not disturbed by the wind, and, if it were, the average of a series of floats which occupied the whole width of the river.

9496. What we might call the mean motion of the whole volume?—Yes.

9497. (*Mr. Lumley Smith.*) I believe you have a note that "the mean displacement between Deptford and Erith is about ⅖ths of a mile per tide"?—Yes.

9498. Why did you take between Deptford and Erith?—I wanted to show what the displacement was for one place, and I took a place where the knowledge of the displacement was a little important.

9499. Have you looked to see whether the quantity of water coming over Teddington Weir was more or less than the mean on that day, the 14th September?—It was about an average quantity.

9500. Is that the only day that you have taken it for?—It is the only day I have made these calculations for.

9501. Upon days when less water was coming over, what alteration would you find in the displacement?—If the quantity of upland water were less, the displacement would be less, and if the quantity of upland water were greater, the displacement would be greater.

9502. Are you able to give my learned friend the formula by which he can calculate the amount of displacement, owing to the water coming over?—The displacement is directly as the volume.

9503. Before we pass from these tables, I wish to ask you this—you have taken the sewage that comes in at Barking and Crossness?—Yes.

9504. Where did you get it from?—I got it from page 17 of Mr. Latham's Report of the sewage flow for 1881, and that worked out to 13,603,000 cubic feet per tide, or 26,000,000 cubic feet per day.

9505. I want your view as to the value of the float experiments, and how far they coincide or do not coincide with what you would expect; first of all, I think you have told us this, but it will be convenient to have it grouped together. If the floats gave a mean down stream travel, they would agree with the diagram?—They would agree with the diagram.

9506. With which of your Tables?—With Table 5.

9507. Do you in fact find that the floats' travels, as shown by the diagram, which Mr. Latham has prepared, agree with what you have shown in Table 5?—The down stream travel of Mr. Latham's floats is very much smaller than it would be according to this diagram.

9508. By "travel," you do not mean travel by the oscillation of the tide, but taking the displacement of the water by other matters taken over a long period?—Yes.

9509. What is the reason why the floats are not displaced to the same extent as the mean volume of the water?—The floats were kept towards the middle of the stream, and the floats are too short to reach down into those layers of waters which move slowest. The floats therefore were in layers of water, which had a greater motion than the mean motion; they will travel over a greater range of horizontal oscillation in a tide, and they represent, not the real mean motion of the water, but the motion of those parts of the water which are towards the centre and towards the top.

9510. Now, first of all, with regard to the top, do you find as a rule that the top moves faster than the mean motion?—In all streams the surface has the greater motion.

9511. And also with regard to the centre?—The centre has a greater motion than the sides.

9512. Then the centre and the surface combined would produce a greater range than the mean motion; or, how is that?—The motion in the centre and at the surface would be considerably greater than the mean motion of the water.

9513. Is there a difference between the range of displacement of the flood and of the ebb; how do you account for the floats being displaced up the river, instead of being displaced down?—I should like to point out that in each tide a float travels a distance of over 24 miles; to take a fair average case it goes 12 miles up stream, and 12½ miles down stream. I am putting a case rather unfavourable to myself; its whole travel is therefore 24½ miles, but its displacement down stream is only half a mile. Now, if from any cause the velocity in the travel up stream is a little greater than it ought to be, or the velocity in the down stream is a little greater than it ought to be, that small alteration of velocity over the 12 miles travel will make a great alteration in the displacement. About four per cent. alteration of velocity up stream will diminish the down stream displacement to nothing; about four per cent. alteration in the down stream velocity would double the down stream displacement. To explain Mr. Baldwin Latham's results therefore, all we really have to do is, to find out whether there was possibly an alteration of something like four per cent. in the velocity of the float during its 12 mile travel up stream or down stream. The alteration in the displacement is very large, but that may be due to a very minute alteration in the velocity during its travel.

9514. You see, taking the 12 miles up and 12½ miles the other way, that makes 24½ miles as the whole motion of the float; and, if you take the ordinary displacement of the mean water at half a mile, its motion is 49 times the actual amount of displacement; therefore, you think that a little variation in the currents or in the velocity would far more than counterbalance that half mile?—Yes; a slight alteration in the velocity either in the up stream or down stream travel will make a great alteration in the tidal displacement.

9515. Is there any difference in the tidal wave or the currents produced by the tidal wave as you go up stream or down stream?—I see some reason to think that the ratio of the central and surface velocity to the mean velocity is greater during the flow of the tide than during the ebb of the tide—I think it is possible that there is quite 4 per cent. more central

*Prof. W. C. Unwin.*

14 Feb. 1883.

and surface velocity during the flow of the tide than during the ebb.

9516. I see that Mr. Baldwin Latham spoke of having seen you upon the subject and quoted your opinion at question 8451 as to the probability of the floats going up the river rather than down. I think he said that in your opinion the possibility was "that "in tidal water in going up the stream the water "obeys the law of the tidal wave, but in coming "down it flows off more generally as a flowing "stream. The consequence is that the velocity of "the tidal wave being very much greater in deep "water where the curve is sharper than it is in the "case of the ordinary flow down, where it is flatter, "the float in the middle of the river would have a "greater tendency to go up upon the tidal than it "would have to come down again upon the ordinary "flow"?—The flow of the tide is purely the phenomenon of a wave of translation propagated up stream and extinguished at the tidal limit. The flow is due to wave action. During ebb there is no wave action, and the water flows in consequence merely of its surface slope.

9517. Will that account for the progress sometimes made by the floats up the stream instead of being displaced by the main body of water down stream?—What I want to point out is that a very small alteration of velocity due to local currents, or any similar cause, will account for the floats behaving in an eccentric way. I think there is a general cause which has sent the floats up stream and that is that the ratio of the central and surface velocity to the mean velocity is greater during flow than ebb. I should like to mention at this point that I examined this morning some very careful current meter observations which were taken at Putney; that is not at all a good station for observing the fact, because it is too high up the river, but I do find there, that the upper portions of the water have a higher velocity in proportion to the mean during flow than during ebb. I can give the numbers if you desire it.

9518. At what parts of the river do you find these discrepancies in the floats?—The greatest discrepancies in the travel of the floats occur in the crooked portions of the river.

9519. Are you able to say whether in crooked parts of the river you find the water affected by the shape of the banks, and so on?—In crooked parts of the river some of the bottom water is brought up to the top—the whole stream twists upon itself and the ordinary ratio of the velocity of the central and the surface water to the mean velocity is very considerably altered. I do not know that that is the explanation, but it seems very probable that in the crooked portions of the river the travel of the floats would be different from what it would be in the straight portions of the river.

9520. Comparing for a moment the travel of the floats with what would be likely to be the travel of the sewage, what differences do you expect, do you think, that they would fairly represent that where a float went sewage might go; or, what other technical considerations do you think would affect the matter, with regard to eddies and so on; which do you think would be most likely to get highest?—The travel of the sewage would be identical with that of the floats, if there were nothing like mixing action; but the floats cannot partake of the eddying motions which mix up the water, and they get none of the travel which is due to the mixing action; the sewage travels faster than the floats, because in addition to the pushing down by the up stream water, it is pushed down by the sea water which is left in the low water volume after each tide.

9521. Now, with regard to the saltness of the river, I think my Lord asked you whether any of the saltness was found by the sewage. I believe you have told us that you got your materials from Professor Way?—Yes.

9522. Have you plotted out from the diagrams certain curves showing the saltness at different parts of the river?—No. 4 diagram shows the saltness furnished me by Professor Way, plotted in the form of curves for three tides.

9523. Your vertical scale shows the number of parts of chlorine in 100,000 parts?—Yes.

9524. You have also taken the quantity of chlorine in sea water as 1961 in 100,000 parts?—Yes, the sea water is shown just under the words "pure sea water" upon the right hand side of the diagram.

9525. It is not quite 2000?—It is not quite 2000.

9526. Then, comparing the saltness with pure sea water which is represented by the top dotted line, or the little black mark just under it; at Erith you seem to get at your ordinate about half the height of sea water?—About half on the high water of September the 14th.

9527. Upon the 14th of September at high water the water at Erith was half as salt as pure sea water?—Yes.

9528. And this diagram shows the amount of saltness in the same 10 places at high and low water upon those three days, the 14th and 22nd of September, and the 30th of November?—Yes.

9529. I notice rather a remarkable bulge, as I may call it in homely language, opposite Barking and Crossness at low water on September the 14th?—With the spring tide there is a rise of the line there.

9530. That comes, does it not, opposite Barking and Crossness?—Yes.

9531. There seems to be a considerable increase of chlorine there?—There is a rise in the chlorine line there.

9532. Whether that came from the sewage or not you do not know; you found it there?—I have simply taken the analyses given me. I should like to point out that the reason of plotting this for my purpose was, to show how very greatly the quantity of upland water affects the position of the chlorine lines; any increase in the quantity of upland water drives down the chlorine lines very much indeed.

9533. If you compare the 30th of November with September the 14th, what do you find?—That the increase of upland water has driven down the chlorine lines very much indeed, and I shall venture to use that presently, because I am going to make an assumption about what would happen if the quantity of upland water were very small.

9534. Have you anything further to say upon that diagram?—Just one word. I notice one thing in Professor Way's analyses, that the saltness of the water taken at the surface is a little, but not very much, less than the saltness of the water taken at a considerable depth. One explanation of that would be that the tidal water found its way up underneath the other water, but it seems to me more probably due to the fresh water of the tributaries spreading out upon the surface, and not all at once mixing with the water below.

9535. (*Sir John Coode.*) If there were no tributaries below Teddington Weir, do you think that the difference between surface water and the water below would remain to the same extent?—I think if there were no tributaries the mixing would be perfect, at no very great distance from Teddington, the action of the mixing is so great.

9536. (*Mr. Lumley Smith.*) Now will you take Diagram 5?—Diagrams 5 and 6 are to be taken together.

9537. You will explain upon what principle you prepared those diagrams, and what they represent?—I have sought to find the condition of the river at different sections in some way which should involve the very smallest amount of assumption. The principle upon which I proceed first of all is this, I say that the water above Crossness consists of pure river water which has come down from Teddington, and of the denser water which has come up from Crossness. Any water which increases the density of the river above Crossness must be water which has passed Crossness on its way up, and therefore I can take the

chlorine analyses, and by means of those I can divide the water above Crossness into pure river water and water which has once been at Crossness. The result of applying that calculation for high water and for low water on September the 14th is shown upon these two diagrams.

9538. I do not know that I quite follow you, perhaps the members of the Commission do,—you say that you can separate the water which has never gone below Crossness from what has been below Crossness, is that by knowing the amount of chlorine in the water below Crossness and also the amount of chlorine in the water which has never been below Crossness?—By knowing the amount of chlorine in the water at Crossness and the amount of chlorine in the water at Teddington, and the amount of chlorine in the water at any given section.

9539. You are not now dealing with the mixture of river water, sewage and sea water by distinguishing between the water which has been below and what has come from above?—That is so.

9540. (*Mr. Michael.*) Have you assumed the chlorine in the mixture is entirely due to the sewage?—I have not come to the sewage yet. I say that anything which increases the density of the water above Crossness is something which has come from below Crossness.

9541. (*Mr. Lumley Smith.*) By observation we can find the amount of chlorine in the water at Crossness, and also above it?—Yes.

9542. Before we pass from that will you explain what your shading lines mean?—The whole of the cross-hatched part, including the part marked "sewage" is the quantity of Crossness water found by that calculation at each section.

9543. You got those different places, Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, Barking, and Crossness. I suppose at Teddington the vertical ordinate represents the amount of water there; that is all fresh water?—It is all fresh water, but it represents the section of the river.

9544. (*Sir John Coode.*) I understand the left hand hatched line represents the whole river section?—Yes, the whole river section.

9545. And the dotted line to the right of that, and the hatched portion to the right of that again represent the proportion of that area which is occupied by water which has once been at Crossness?—Yes, by water which has once been to Crossness.

9546. (*Mr. Michael.*) And the outer division is occupied by water which has not reached Crossness?—Yes.

9547. (*Mr. Lumley Smith.*) Starting at Teddington as Sir John Coode has pointed out, that upright ordinate represents the section of the river?—Yes.

9548. And the whole of that is pure water which has never been below Crossness?—Yes.

9549. When we come to Chiswick a vertical ordinate drawn there would represent the section of the river, and it also would represent water which had not been below Crossness?—That is so.

9550. When we come to St. Paul's Pier, having passed Chiswick, we find that the section of the river is partly occupied by water which has been below Crossness, and partly by pure river water?—That is so.

9551. It slightly increases until you come to Crossness, when the whole of it is water, with the same amount of chlorine as you get at Crossness?—Yes.

9552. The cross-hatched part would represent the Crossness water, and to get the relative amount of pure water and Crossness water at any point you have to draw an upright ordinate and compare the length of that in the white with the length of it in the cross-hatched part?—Yes.

9553. Before you pass away from the left hand portion of the diagram are you going to speak of the additional cross hatching for "sewage," or will you wait later to come to that?—I think I would rather deal with the Crossness water first. Taking the right hand diagram, I say that below Crossness the water in any section consists of water which has come up from the sea and the water which has gone down from Crossness.

9554. You know the amount of chlorine at Crossness, and you know the amount of chlorine in sea water?—Yes.

9555. Therefore anywhere below Crossness, by seeing how much chlorine there is in a sample pailful of water, you can tell how much water has come from above Crossness and how much has come from the sea?—Yes, quite so.

9556. Will you explain what you have done?—I have calculated for each of those ordinates; the portion of the section which is occupied by Crossness water and the proportion of the section which is occupied by sea water.

9557. Does that dark line represent the section of the river?—The dark line represents the section of the river, the scale being now reduced 10 times.

9558. And then you find at Crossness that the whole of the river is occupied by Crossness water?—The whole of the river at Crossness is occupied by Crossness water.

9559. At Southend it is diminished very considerably; nearly the whole of it is sea water?—Yes.

9560. So that at any part from Crossness to Southend the relative quantity of water from above Crossness and sea water can be ascertained by simply putting the scale in the ordinate drawn uprightly?—Precisely.

9561. You also show the ratio of the Cray and Darenth water; why is that?—The only tributaries of importance in the water below Crossness are some which come in between Erith and Gravesend, and which for my purpose I assume come in at Gravesend. I have assumed that those consist of pure water, and on that assumption I have tried to find out how much modification of the diagram would be necessary to allow for that quantity of water coming in at Gravesend; and I have drawn the area of the Cray and Darenth water; there are several other tributaries, but I call it "Cray and Darenth"; they are the only important ones, and their position on the diagram shows that they do not very much affect the whole question.

9562. Is the amount of water that comes in there included entirely in that little cone of dotted lines above the cross hatch?—The space occupied in the river by water which had come in from those tributaries is represented by the area between those two dotted lines; it is not very material. Then I should like to point out that I have handed in Tables 6, 7, 8, 9, 10, and 11, which contain the figures relating to this diagram and to the two other tides. I have not plotted the two other tides, but I have calculated them. I have given in these tables the area of the river water, sea water, Crossness water, and Cray and Darenth water at low and high water for three tides.

Adjourned to Tuesday next at half-past 12 o'clock.

# TWENTY-THIRD DAY.

## Tuesday, 20th February 1883.

PRESENT:

SIR P. BENSON MAXWELL, IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, ESQ., F.R.S., *Secretary.*

20 Feb. 1883.

(*Mr. Bidder.*) Probably you will recollect that when Mr. Mansergh was in the box and put in his diagrams, he stated that they were prepared from 134 sections which he had made of the river, and we asked him to allow us to have an opportunity of copying them out, and he was very ready to do so. We have not had that opportunity yet, and, as my learned friend is here, I would ask that we should have it now.

(*Mr. Balfour Browne.*) I remember distinctly Mr. Mansergh said that he had arrived at his results from a large number of sections.

(*Mr. Bidder.*) And then I said, Of course you have no objection to let us have them, and he said, certainly not.

(*Mr. Balfour Browne.*) Subject to the opinion of my leaders, I have no objection to your having them.

(*Mr. Bidder.*) But is it subject to anything, because I will give you the reference to the passage in which Mr. Webster agreed to our having them.

(*Mr. Balfour Browne.*) I will promise to discuss the matter with my learned friends this afternoon, or before to-morrow's sitting, and if they were promised by Mr. Webster, my learned friend will keep his word.

(*Mr. Bidder.*) But even if they were not promised, I should make the application.

(*Chairman.*) Would your application be in the nature of an order upon the witness?

(*Mr. Balfour Browne.*) If there is anything in the way of furnishing information by myself or by our witnesses, we shall be happy to do it.

(*Chairman.*) Let us put it aside for the present, I dare say there will be no difficulty about it.

Professor WILLIAM CAWTHORNE UNWIN recalled; further examined by Mr. BALFOUR BROWNE.

*Prof. W. C. Unwin.*

9563. I think upon the last occasion when the Commission adjourned, you had just called attention to tables 6 and 12, and also to diagrams Nos. 5 and 6; those diagrams I think show the divisions of the water. I want to ask you this question, do those diagrams depend upon any theory of yours, or are they simply a putting in a diagrammatic form, Professor Way's analyses?—The diagrams and the six tables relating to the three tides as far as they relate to the division of the water above Crossness into Crossness water and river water, and as far as they relate to the division of the water below Crossness into sea water, and Crossness water, depend upon no theory, they are a simple expression in volumes of Professor Way's analyses. Those are the six tables relating to the three tides, Nos. 6 to 11 inclusive, and Diagrams Nos. 5 and 6.

9564. (*Mr. Bidder.*) Do Diagrams 5 and 6 relate to those tables?—Yes.

9565. And are founded upon them?—Yes, they are simply a graphic representation of two of the tables.

9566. (*Mr. Balfour Browne.*) Of course these diagrams simply represent the condition of things at the moment of analysis?—They represent the condition of the river at high water and at low water.

9567. As indicated by the chlorine?—Yes, as indicated by the chlorine.

9568. I want to go now to the question of the quantity of sewage in the Crossness water; what would you divide the Crossness water into?—The Crossness water consists of river water, sea water, and sewage mixed.

(*Mr. Bidder.*) Does that mean water which has come out of the Crossness sewers?

9569. (*Mr. Balfour Browne to the witness.*) What you are speaking of is water in the river at Crossness?—By "Crossness water" in each of these tables I understand, water which was in the river at the moments when the chlorine analyses were made.

9570. (*Sir John Coode.*) Do you mean taken at the centre, or at the one side or the other side, or both sides or how?—Professor Way can tell you that better than I can. I believe they were taken across the river.

(*Mr. Balfour Browne.*) They were taken across the river, three or four samples at each section of the river, and I believe the mean of the whole was taken.

(*Mr. Bidder.*) What Professor Unwin means I believe by Crossness water, is the water which was represented by a certain analysis which was said to have been taken of the water at Crossness.

(*Witness.*) I might take any section of the river and divide it in this way; above, into water which was as salt as pure water, and water which was as salt as that at the section; below, into water which was as salt as that at the section, and water which was as salt as sea water.

9571. (*Mr. Bidder.*) But your samples were not taken at the same moment?—There were six sets of analyses, three of them taken at high water on one tide, and three of them taken at low water on another tide.

(*Sir John Coode.*) No. 6 is taken at low water on September 14th; No. 7 at high water on September 14th; No. 8 at low water on September 22nd; No. 9 at high water on September 22nd; No. 10 at low water on November 30th, and No. 11 at high water on November 30th.

9572. (*Mr. Balfour Browne.*) What you have done I think is to take one of those tables and turn it into a diagram?—I have taken two of them.

9573. At high water and low water?—Yes, at high water, and low water on September 14th.

9574. And those diagrams are given as Nos. 5 and 6?—Yes.

(*Sir John Coode.*) You will give evidence by and by to show exactly how these samples were taken?

(*Mr. Balfour Browne.*) Certainly we shall.

(*Mr. Bidder.*) In point of fact they are the foundation of all the diagrams and tables which the witnesses have been serving up to us in so many forms.

(*Sir John Coode.*) Therefore it is all important that we should know how they were arrived at.

9575. (*Mr. Balfour Browne to the witness.*) With

regard to the Crossness water, which as you say, consists of sea water, river water and sewage, how do you find out what quantity of sewage is in that water; what process do you go through?—There are three quantities to determine, and we must therefore have three equations; those are based upon these three conditions, first, that the sum of the salt in the river water, of the salt in the sea water, and of the salt in the sewage must be equal to the observed quantity of the salt of the section, that is to say, the total quantity of the salt in the river water, sea water and sewage, must be equal to the observed quantity of the salt of the section. Secondly, the sum of the areas of the river water, sea water, and sewage, must be equal to the known area of the section. And, thirdly, the ratio of the water of the river and sewage water must be equal to the known ratio of the quantity of sewage supplied in a tide, to the quantity of upland water supplied in a tide.

9576. Which is the most important thing in this place to determine, the quantity of sewage, or the proportion of sewage in the water at Crossness, what other point?—The point to determine is the quantity or proportion of sewage in a cubic foot of water; we are interested in the sewage more than in the other constituents of the water.

9577. So far as we are concerned, it does not matter how much is river, how much is sewage, and how much sea water, but how much is sewage in proportion to those—that is the important point?—Yes.

9578. The quantity of sewage in a unit volume of water at Crossness, you give for this purpose a particular name to?—I call it the sewage density.

9579. And have you given values to it in your tables?—It is given in two columns in the six tables to which I am referring.

9580. The heading of the column is "Ratio of sewage section to whole section"—now, whenever the water of Crossness goes down stream, or up stream, does it carry the same proportion of sewage with it?—It carries with it the same proportion of sewage, or of materials which have been sewage.

9581. The question whether they have ceased to be sewage is of course a chemical question?—That is a question which is out of my view.

9582. Can you therefore divide the Crossness water for the whole length of the river into sewage water, and not sewage water?—The tables and the diagram show the distribution of sewage obtained by dividing the Crossness water into sewage, and water which is not sewage.

9583. And that shows the volumes at every part of the river?—Yes.

9584. I see that one-half of these diagrams is on a very exaggerated scale, it is exaggerated five times?—It is exaggerated ten times upon these two diagrams.

9585. And that curve upon that diagram No. 5, shows the distribution of sewage, the whole length from Teddington to Southend?—Yes.

9586. And the same with diagram, No. 6, only taking it to Southend at low water?—Yes.

9587. Are those two diagrams drawn to the same scale?—Yes, they are drawn to the same scale.

9588. There may be something said as to the way in which the sewage enters at Crossness, and have you made calculations upon various hypotheses, the first of which is upon the supposition that it enters uniformly at Crossness?—In dividing the Crossness water into sewage water and water not sewage, I have assumed that the sewage at the Crossness section bears the same ratio to the river water that the sewage supplied in a day bears to the upland water supplied in a day. In order that that assumption may be right, I must assume that the sewage is uniformly delivered into the river during the period of an ebb.

9589. In what time is that?—Between six and seven hours, that is at all events, I assume that it is so delivered that, over about 10·8 miles length of the river, it is distributed uniformly. Now if the only sewage in the river were that delivered in one tide, the assumption would not be a very exact one; but as the length of river corresponding to the tidal range, about 10·8 miles at Crossness, contains the sewage of from 12 to 15 days, or from 24 to 30 tides, then the slightly non-uniform distribution of any one day's sewage very little affects the question. The mixing action which goes on in that length of tide will make the distribution tolerably uniform, and the non-uniform distribution of one day's sewage as I say, very little affects the question.

9590. If, of course, the Crossness water were passing into an absolutely pure river, the result would be different?—In the case of an absolutely pure river, I should consider the supposition not an exact one, but the quantity coming into the river on one tide being only one twentieth or a thirtieth of that in the whole section, the uniform distribution of it does not seem to be very important.

9591. Do you make any correction or allowance for the tributaries running into the Thames; first, taking a pure tributary above Crossness?—If a pure stream enters above Crossness its saltness is the same as of the Teddington water, and by the method I have adopted, it is estimated as Teddington water; therefore it does not involve any error in the tables.

9592. If a polluted tributary enters the river above Crossness, what is the result?—If a polluted tributary enters the river above Crossness, its saltness is very much less than the saltness of Crossness water, which contains a portion of sea water; therefore a polluted tributary which enters above Crossness will be chiefly estimated as Teddington water; and therefore to the extent to which polluted water enters above Crossness, the diagram shows less sewage than there really is in the upper part of the river.

9593. Having shown the Commission what took place when these samples were taken at high water and at low water on the 14th September, I want to ask you this: up to this point you are dealing with what I understand you to say are actual facts if the chemists are accurate; but what would happen in the case of excessive dry weather?—The diagram and tables simply represent the condition of things observed by chemists upon three actual days; on one of those days, the 14th, there was about the mean quantity of water at Teddington; on the other days there was a great surplus of water at Teddington. It seems useful to inquire what would happen if the supply of water at Teddington were reduced to its lowest summer amount, and I have calculated an imaginary tide corresponding to such a period of drought.

9594. Coming in wen the supply of water was excessively low?—Coming in when the supply of upland water was excessively low.

9595. Such a tide as might come in in dry summer weather, is that so?—Quite so.

7596. Will you explain what you mean?—The only pure assumption one has to make, is the assumption about the amount of saltness in the river. The diagram of saltness (No. 4.) shows clearly that as the supply of upland water is diminished, the amount of saltness in the river increases, and goes further up stream. Looking at that, I have made this assumption: I have supposed that the saltness of the river from Crossness towards the sea would be exactly the same as on the 14th September.

9597. (*Mr Bidder.*) At high or low water?—I have only calculated the low water—that from Crossness upwards, the saltness would uniformly diminish to Teddington.

9598. (*Mr. Balfour Browne.*) Have you taken a quantity representing the quantity of upland water?—The volumes I took were, for the upland water 30,000,000 cubic feet in a tide, and for the sewage 10,000,000 cubic feet in a tide — that is 3,450,000 less than I have taken on ordinary days.

8599. The 3,450,000 you are speaking of less, only refer to the sewage?—Yes, the upland water is the known minimum supply at Teddington, and the sewage I have taken at 3,450,000 cubic feet per tide less than the ordinary supply; making the calculation, I find

*Prof. W. C. Unwin.*

20 Feb. 1883.

that there would be at Crossness one cubic foot of sewage in five cubic feet of water. Then, proceeding as with the other tides, I have calculated the quantity of sewage at other sections of the river, and that is given in Table 12.

9600. (*Chairman.*) Do you show that upon the diagram ?—No, the calculations corresponding to those I have been speaking of are given in Table 12.

9601. (*Mr. Balfour Browne.*) Can you tell from those tables the total sewage above any section of the river in days' supply ?—Yes, estimated in days' supply. It appeared to me that the most convenient unit for considering the amount of sewage would be a day's supply of sewage. I have taken a day's supply of sewage at 26,000,000 cubic feet. Now, in Table 14 and in diagram 8, I have shown by ordinates the total sewage above any section in units of days supply. It will be seen that the total number of days' supply in the river was a little over 39 days upon September 14th, and a little over 28 days, from 28 to 31 days, upon the 22nd, and a little over 12 days upon November 30th.

9602. You have put upon this diagram in a solid black line, an "Ideal low-water spring tide;" what does that run up to ?—In a period of drought I estimate that there would be 59 days' sewage in the river.

9603. Upon this diagram one side is the same as the other, only multiplied by five ?—Multiplied by five.

9604. Does this show the mean ? Have you calculated upon the table the mean of high and low water ? —I have not. I think upon the whole it is preferable to deal with the conditions of the tide independently.

9605. I see that you put down both the high and low water upon all the observed days ?—Yes.

9606. And the ideal low water is calculated in the way you have described to the Commission ?—Precisely so.

9607. Which only depends upon the one assumption as to the saltness which you have described ?—Only upon that one assumption as to the saltness.

9608. Have you worked out the percentage of sewage or material derived from sewage in the water, and in which table is that shown ?—In Table 15 and in diagram 7, I have shown the percentage of sewage in the water. The interesting part of that diagram is, I think, the way in which the percentage of sewage is extraordinarily diminished upon the 30th November, when the supply of upland water was very large ; and in connexion with that you will notice the very great rise of the ideal spring tide line in drought, at low water, which is due to the known diminution of the water at Teddington.

9609. The very fact that the line representing the percentage of sewage upon the 30th November is very much depressed, is the correlative fact to the one that the ideal spring tide is very much elevated ?—Precisely so.

9610. Showing that the effect of the upland flood water is very great in driving the sewage out ?—Precisely so.

9611. Have you considered the effect of removing the sewage outfall from Crossness or Barking to Gravesend ?

(*Mr. Bidder.*) But I thought it was understood——

(*Mr. Balfour Browne.*) I am not going into any question of remedy, it is simply a question of volume again.

(*Mr. Bidder.*) I am quite willing ; but I thought it was decided to limit the inquiry to that branch of it which the chemists were inquiring into, namely, the present state of things.

(*Chairman.*) Let us see the object of the proposed question.

(*Mr. Balfour Browne.*) The question is, how much it would reduce the sewage density if, instead of the sewage being poured in at Crossness, it were poured in at Gravesend. I am not proposing another scheme to deal with the sewage, but simply asking what would be the effect upon the density under these altered conditions.

(*Mr. Bidder.*) That is a very simple question, but it opens the floodgates to the whole of the other branch of the inquiry.

(*Witness.*) I should be very glad not to give an answer to the question.

(*The Commissioners consulted together.*)

(*Chairman.*) We think that though we adhere to the line we originally proposed to ourselves, namely, to address ourselves to the remedy as a distinct branch if we should think a remedy is necessary ; still we do not think we ought to draw a hard and fast line for the purpose of excluding a question like this. I understand you to say that you do not put the question for the purpose of inviting the witness to give his opinion as to what remedy he would propose, supposing a nuisance to be created.

(*Mr. Balfour Browne.*) Certainly not ; it is only to show how much the density of the sewage would be diminished, if instead of being poured in at Crossness or Barking, it were poured in at Gravesend.

The Commissioners allowed the question to be put.

9612. (*Mr. Balfour Browne to the witness.*) Would you answer the question. What would be the effect upon the sewage density, if, instead of the sewage being poured in at Crossness, it were poured in some miles lower down ; say, at Gravesend ?—After the most careful consideration of the way in which I have been dealing with known facts, it appears to me that if you introduced the sewage at Gravesend instead of introducing it as now at Crossness and Barking, the amount of sewage throughout the river would be reduced to a little less than one half. You would not do more than that ; and the bearing of that statement upon the inquiry is that there is no point upon the river at which the sewage can be introduced which will keep the sewage entirely out of the upper part of the river.

9613. You wrote a little work upon the movement of water in a tidal river with reference to the position of sewer outfalls, and it is published by Messrs. Spon, I believe ?—Yes.

(*Sir John Coode.*) Is it of any tidal river, or, of the Thames in particular.

(*Witness.*) The work was called "the movement of water in a tidal river," and the calculations were based upon the Thames.

9614. (*Mr. Balfour Browne.*) When did you write this work ?—It was written last December, shortly before I came into any relations with the present inquiry.

9615. There are one or two things which suggest a question. I see on page 8 of the work you say——

(*Mr. Bidder.*) I think this is hardly a convenient way of examining the witness.

(*Chairman to Mr Balfour Browne.*) You might use the pamphlet as your brief, and ask him what is his opinion upon a certain point.

(*Mr. Balfour Browne.*) The only reason is that Professor Unwin has explained his views very clearly, and there would be a risk of misunderstanding unless you had the book before you.

(*Chairman.*) The question the learned counsel would put to you is, are you of opinion that the tidal action alone effects directly any change in the material water in the river.

(*Witness.*) I think the statement there is strictly correct, that the tidal action alone independently of any mixing, effects no change in the material water in the river.

9616. Then what is the nature of the action of the tide ?—The action of the tide alone, apart from what I have classed as mixing action, is merely to produce a comparatively short reciprocating oscillation.

9617. About what length ?—6 to 10 miles upon a spring tide.

9618. And upon a neap tide ?—Upon a neap tide less.

9619. (*Mr. Balfour Browne.*) Does that which you

have stated to the Commission about oscillation take into consideration the mixing action or not?—It expressly excludes the mixing action; that is accounted for afterwards.

9620. Mr. Latham I think quoted from his work when he was in the box. Then on page 10 you say Volume not a very large factor in tidal action."

*Mr. Bidder* objected to the question.

*The Chairman* intimated that the learned counsel had no right to read the pamphlet to the witness to ask him if it was correct, but that he might use the pamphlet as a brief, as suggesting hints for the examination of the witness in chief.

(*Mr. Balfour Browne to the witness.*) Is it your opinion with regard to the mixing action that volume i s not a very large factor in the tidal action?—There is clearly some mis-apprehension there.

9621. Will you just explain what you mean?—What I have said expressly, is that the volume of water which is exchanged with river water in one tide, is not large compared with the whole tidal volume; I still think that that is quite correct.

9622. I will ask you another question without reference to the book; is the general effect of your calculations to show that the exchange of sea water and river water takes place more slowly than is commonly supposed?—That refers to my opinion expressed earlier, that many people think there is a more or less complete emptying of the river and filling of the river upon every tide, and it is strictly accurate to say that that is not true.

9623. It refers to what you have just explained to the Commission, I think?—Quite so.

9624. (*Mr. Bidder.*) I never met a person who thought the river was completely emptied and completely filled at every tide?—I think I could find some statements implying that view.

9625. (*Mr. Balfour Browne.*) I think I understood you on the last occasion, when dealing with the oscillation of water in the river, to say that you thought the float observations were valuable for ascertaining the amount of tidal oscillation?—My point is that the floats show a range of tide somewhat greater than the actual mean oscillation of the tide, but that the floats do show the actual motion of a certain portion of the water.

9626. For that purpose you have treated them as you have done?—Yes.

Cross-examined by Mr. Bidder.

9627. Now I gather that of personal observation of the Thames in connexion with this question, you have none?—I have made a good many observations upon the Thames.

9628. Of course we have all been upon the Thames; there is nobody here who has not been on a penny boat at some time or other; but of personal obsetvations you have not made any, have you?—I have made many observations of a kind which throw light upon this inquiry.

9629. All your diagrams, and all your tables, and all your evidence before the Commission, are based upon three classes of facts I think; just follow me please and see that I am right; first, certain measurements of sectional area of the river which you obtained from the engineers; is that right?—Quite so.

9630. Secondly, certain gaugings of the upland water, and calculations of the amount of sewage, which you got from Mr. Baldwin Latham?—Yes.

9631. Thirdly, upon certain analyses of Professor Way, as to what he found to be the number of parts of chlorine in 100,000 parts in certain samples of water which are said to have been taken from the river at certain times?—Yes.

9632. That is the whole substratum of fact upon which the edifice has been erected; do not let me leave anything out, I think I have got it all; and the distances of course you got from the plan or the ordnance map; but there is nothing else, is there?—I think that embraces the most material facts I have to deal with.

9633. You had to make a certain number of assumptions in arriving at these conclusions, had you not?—So far as I have made any assumptions, they have been quite explicitly stated.

9634. Do not suppose for a moment that I am complaining in any way of the manner in which you have given your evidence. I am not suggesting that the assumptions were not put forward with perfect frankness and fairness, but I should like to ask you this question. In the first place, where is Table No. 1?—Table No. 1 is only a table of areas, and I did not think it worth printing.

9635. It sometimes does so happen, but I think for the moment it is the most important table of the lot. Now, first I will take Tables Nos. 2 and 3, and I think you will want Table No. 1 to answer my question. Taking those tables, I find that you have given us the volumes between consecutive sections in cubic feet. In the first instance Table No. 2 relates to two tides, September the 14th and 22nd, both at high and low water?—Quite so.

9636. Now I have before me a similar table which was put in by Mr. Mansergh, the engineer, namely, Table M 3*a*. I do not know whether you are aware of it, but the results in Mr. Mansergh's table, appear to differ considerably from those in yours. I will ask the question generally, first, you are aware that Mr. Mansergh has dealt with exactly the same facts, and has produced certain results from those facts?—Yes, I am aware of that.

9637. Are you aware that Mr. Baldwin Latham has also given evidence making deductions from those same facts?—I am.

9638. Are you aware that Mr. Peregrine Birch has also given evidence making deductions from those same facts?—I am.

9639. Are you aware that you differ in some respects among yourselves very considerably?—I am not aware of that.

9640. Upon this subject of area and volume, as far as I can make it out, there are differences between you and Mr. Mansergh. Upon what principle have you arrived at the contents of each division; how did you get at it; what you were given as I understand, were sectional areas?—I have taken the mean of the two sections and multiplied by the distance between.

9641. Do you mean to say that if one section were 100,000 feet and another were 120,000 feet, you have taken 110,000 feet and multiplied it by the distance?—Quite so.

9642. Are you not aware that that is utterly wrong as a matter of arithmetic; do not you know that the cubical content and the volume of the river cannot be arrived at in that way; that in many cases it would give a most erroneous result?—I believe it is the most accurate method which you can adopt with the number of sections and with the data which are here at disposal.

9643. But pardon me, supposing you get a river gradually widening, either a conical section or prsimatic section or whatever you like, surely you know that the area of that section is not represented by the mean of the section multiplied by the distance?—In all practical problems, it is no use attempting an accuracy beyond the accuracy of your data, and anyone who will look at the longtitudinal section of the river varying from yard to yard in the section, will know that the conclusions at which I have arrived are as accurate as any conclusions from those data are likely or possible to be.

9644. But you know there is a recognized formula for dealing with these matters, any engineer's clerk would have known how to go to work about it?—There are many rules, prismoidal rules and so on, which are more accurate than those which I have adopted, in the case of railway embankments for instance; but I believe they would be less accurate

*Prof. W. C. Unwin.*

20 Feb. 1883.

in the case of the river, which I have had to deal with.

9645. You mean they would be more accurate with a regular widening, but you admit that the plan you have adopted, would give an erroneous result in the case of a river, supposing it were a case of regular increase?—The prismoidal rule is as much a theoretical rule as the one I have adopted.

9646. But you know that the prismoidal rule is not a theoretical rule, in the sense of being uncertain you know; it is as certain as that two and two make four.

(*Chairman.*) But is that so, because it is rather putting it to the witness as a statement?

9647. (*Mr. Bidder.*) I should strictly perhaps have asked the witness, whether it was true that two and two make four. (*To the witness.*) Do not you know that what you call the prismoidal rule is matter of absolute demonstration, assuming the river is regular in its increase?—If you make that assumption.

9648. Will you first answer the question, do not you know that what you call the prismoidal rule is a matter of absolute demonstration, assuming that the river is regular in its increase?—I must ask you to define what you mean by "regular increase." There is no railway embankment and no river in which the increase is exactly regular.

9649. (*Chairman.*) Assuming Mr. Bidder's fact that the river does increase regularly, then is not the prismoidal rule one capable of mathematical demonstration?—There are many kinds of regular increase; for one kind of regular increase, the prismoidal rule is exact, and for another kind of regular increase, it is not exact.

9650. (*Mr. Bidder.*) If the river increases regularly in this sense, that for instance from one area to another, you might join straight lines, so that it is part of the frustrum of a pyramid, then would not the prismoidal rule apply?—That is not the basis of the prismoidal rule, a prismoid has two edges parallel.

9651. I assume that I know what you mean by the prismoidal rule, it means this, does it not, that taking the section of the river at one point and at another point, and assuming the variation of the upper small section, to the lower and larger section, as represented by joining them by straight lines, then the prismoidal rule is absolutely accurate?—No that is not quite so.

*Mr. Bidder sketched a diagram, and exhibited it to the Witness.*

9652. Does the prismoidal rule exactly apply there?—You have drawn your lines to meet in a point, they may meet in a line. The solid may be a wedge.

9653. (*Mr. Abernethy.*) Is there any section of the River Thames where you could connect the sections by a straight line in that way?—Certainly not. It is my deliberate opinion that the plan I have adopted, is the best plan that could be adopted in the particular case which I have been calculating.

9654. (*Mr. Bidder.*) But if the increase were regular in the sense in which I have drawn it here, then is the prismoidal rule the right one?—Not if the regular increase is the increase of a wedge.

9655. But I said if the increase is a regular increase in the sense in which I have drawn it here?—But you have added the assumption that the river goes to a point.

9656. No, not at all. Now again, to put it another way, there is no known form of increase in which your plan would be right, is there?—Yes, certainly there is.

9657. What is it?—There is certainly a mode of increase in which it would be right, though I am not prepared to work it out at the moment.

9658. In fact, I think I may put it in another way—let me suggest this—if the area of the river increased without any increase in width, but simply increased by increase in depth, then your formula would be nearly right?—And equally if it increased in width without increase in depth.

9659. If it increased only in any one dimension, but that is not what it does?—It is very nearly so; it is very nearly constant in depth, and increases in width.

9660. Are you very positive that the Thames does not increase in depth?—Between any two sections the increase in depth is not very great, but the increase in width is sensible.

9661. Do you know to what extent your adoption of that rule as compared with the rule which the engineers have adopted has brought out a totally different result?—I protest against the term "which the engineers have adopted," because the whole of the canals in India, I believe, have been taken out upon the plan I have followed.

9662. Do you know that the rule you have followed has brought out a totally different result from that brought out by Mr. Mansergh, and to what extent you differ?

9662*a*. (*Chairman.*) Do you know what it amounts to?—I do not know upon what rule he worked.

9663. Do you know that there is something like 25 per cent. between Mr. Mansergh's figures and yours?

9664. (*Mr. Bidder.*) Take your Table No. 2 and I will take one illustration—the 14th of September. Mr. Mansergh has divided the river into two sections, above and below Crossness; now take high water of the 14th of September, and below Crossness, I think you will find that you represent 448,880,000, which you will get by adding the three last figures together?—Yes, about that.

9665. Now, if you will look at Mr. Mansergh's paper for the very same day and time, Table M 3*a*, from Crossness to Southend, and if you add the figures in his No. 3 column for high water upon the same day you will find that they come to 352,893,000?—I will assume that you are right, and I will give you an answer why it is.

9666. I had rather you did not assume that I was right, because afterwards it might be said "Still you were wrong after all"?—These are rather awkward figures to add up.

9667. I will only point out to you that Mr. Mansergh's content is represented by 352,000,000 and yours is represented by 448,880,000?—I will only remark upon that, that out of my whole volume of 448,880,000 cubic feet, 367,900,000 cubic feet are in one single section; that is the section between Gravesend and Southend; that happens to be an immensely long section, and immensely wide; and, as we have only two cross sections for that immense volume, which is more than three fourths of the whole volume, there is likely in that section to be a great difference between us.

9668. But pardon me; this just shows the result of taking this unusual formula of yours, you and Mr. Mansergh were working upon precisely the same materials?—Yes.

9669. And having exactly the same materials to go on, you have brought out results which vary to the extent of 27 per cent.?—The fault is want of data, not defective calculation; the want is of more sections between those two points.

9670. Then the data are so defective, that the greatest and ablest men of their age may vary in the results they produce by 27 per cent.?—In this particular instance, the data between Gravesend and Southend are defective, if you want to follow them out to get exactly the content of the river.

9671. But just follow that out, the defective data leading to the difference as to the content of the river lead also to differences in the quantity and proportion of the sewage in the river?—In one section they do.

9672. And that is the biggest section containing three-fourths of all the water; the section below Crossness?—I believe we have all been perfectly well aware, that in that section, we had very few sections by which to determine so very large a volume.

9673. And that section being the section which according to your assumption contains three-fourths of the water, and three-fourths of the sewage which you are giving evidence about below Crossness?—I thought that the interesting part of my evidence related to another part of the river.

9674. I am told that if I go to the upper parts I

shall find, though not quite so great an extent of discrepancy, still a very large extent of discrepancy; I am afraid up there, your sections are not quite the same as Mr. Mansergh's?—I really have not looked at Mr. Mansergh's results at present; I have been too much engaged upon other matters.

9765. Still I put it to you, if you and Mr. Mansergh, both being eminent men, looking at these data, come to results with a difference of 27 per cent., how can the Commission rely upon the results you arrive at, upon other points of the case?

(*Chairman.*) That might be put to the Commission rather than to the witness.

(*Mr. Balfour Browne.*) But Mr. Mansergh had at his disposal a very large number of sections which Professor Unwin had not at his disposal at all.

9676. (*Mr. Bidder.*) Then that is your first assumption that that formula, taking the mean, will give you correct results?—I protest against your saying that I am of opinion it will give me correct results, I say that taking the only data at my disposal, it was the best method I could follow; if I had had a greater number of sections at my disposal, I might have followed another rule.

9677. Your next assumption was that the ratio of the sewage to river water upon any particular day is equal to the known ratio of the sewage coming out of the sewers to the upland water as gauged upon that day?—That is putting it inaccurately. Surely, I have not said anything exactly equivalent to that; I have certainly not said that; what I have said, is that at a particular section, the Crossness section, the quantity of upland water, and the quantity of sewage which crossed the section in one tide are known, and their ratio is known.

9678. You followed, as I understand, the same process as Mr. Mansergh did—you have taken Professor Way's analysis of chlorine, and you have deduced from that inferentially the proportion of sea water and fresh water, have you not—that was your first step?—I have nowhere done that.

9679. Then if you have not got it from Professor Way, from what source have you got the proportion of sea water and fresh water in any section of the river?—I have nowhere calculated the proportion of sea water and fresh water in the river.

9680. Then it must be my fault. Will you tell me upon what theory you based your inferences as to the proportion of sea water and fresh water in the river. I will take for instance, Diagram No. 7, at low water spring tide on September the 14th at Crossness; I find for instance at Crossness, that you got 12 per cent. of sewage upon the whole section, and you also give in Table 6 in certain cases though not in others, the area of sea water, and the area of Crossness water, and so on?—Yes. I want to point out that my method is in no way identical with Mr. Mansergh's.

9681. Then I was mistaken in supposing that you had adopted a similar method to that taken by the others. Now, take Table No. 6, the first column gives us what Professor Way gave you, the chlorine in 100,000 parts of water at certain places at low water upon the 14th of September—that is information received from Professor Way's analyses?—Yes.

9682. The next column is the sectional area as given by the engineers?—Yes.

9683. Now after that, having got those particulars, will you just explain how you went forward and got the rest?—Shall I take one section.

9684. Take Crossness, the one I pitched upon with 470 parts of chlorine?—I say that at the Crossness section there were at low water upon that tide 30,337 square feet of Crossness water.

9685. Inasmuch as you call Crossness water that which was at Crossness at that time, that is simply saying that X is equal to X, and I am about where I was you know. Perhaps you will tell me, how from that interesting and recondite fact, you produce the further fact, that the area of sewage was 3,761, and the ratio of the sewage was 12 per cent.?—I say that at the Crossness section there were 3,761 feet of sewage in the section.

9686. Where does that come from?—That you have crossing the section at Crossness in one tide, 69,150,000 cubic feet of pure upland water, and 13,450,000 cubic feet of sewage.

9687. Now with regard to the 13,000,000 cubic feet of sewage, I can easily understand how you get that—that is a little more than half a day's sewage?—It is very little more than half a day's sewage, because I take the tide at 12 hours 25 minutes.

9688. Now upland water at Crossness 69,000,000 cubic feet, where did that come from?—That was the gauging at Crossness on that day.

9689. You could not have had a direct gauging of the quantity of upland water at Crossness; that is impossible?—If you wish I will explain what the whole method of these calculations is—it must be understood that the external conditions remain constant, and that if there were 69,000,000 crossing upon the 14th of September, there had been that quantity crossing for a whole month.

9690. But how do you know there had been 69,000,000 cubic feet of water crossing on that day, to begin with?—I mean that 69,000,000 cubic feet crossed the Teddington section upon that day, and came in from tributaries.

9691. Mr. Baldwin Latham gives me in his figures at Teddington Weir, 83,000 cubic feet a minute, and I suppose that is equivalent to your figures?—It is equivalent to 69,000,000 cubic feet per tide; that corresponds with Mr. Baldwin Latham's gauging upon that day at Teddington.

9692. Now I will not interrupt you, but I will ask you to complete your story before I ask you any more questions—69,000,000 cubic feet is Mr. Baldwin Latham's gauging at Teddington upon that day, and 13,000,000 cubic feet is the known sewage discharge; now how do you get to the other figures that the area of sewage is 3,761 square feet, and that your percentage is 12?—The 69,000,000 cubic feet put into the tideway at Teddington, push an equal quantity of water which had come from Teddington across the Crossness section.

9693. But I have not got to the 12 per cent. yet?—Then the ratio of the sewage which entered at Crossness in the period of a tide, to the quantity of river water which crossed the section in that period of the tide, comes out if you calculate it, to the value I have given there as K equals 0·1945.

9694. A little less that a fifth?—Yes, now we can make this calculation; the whole saltness of the river water, sea water and sewage in the Crossness section, is equal to the observed saltness of the section. The areas of the three quantities must be equal to the total area of the section, and the ratio of the upland water to the sewage is 0·1945.

9695. Saying that the whole saltness is equal to the observed saltness of the section, is only saying in other words, that Professor Way's analysis represents truly the saltness of the river?—Only that the saltness of the three individual sections must add up to Professor Way's 470 parts.

9696. Your first equation which I believe is perfectly certain, is that the saltness contributed by the constituents must represent the aggregate saltness, you deduce from the 470 grains, which Professor Way has observed implicitly, (You do not do it explicitly) how much sea water, and how much river water there was in the river; that is to say, how much sewage and and how much sea water?—Yes.

9697. Then you deduce from what you call your K, the percentage of the fresh water which is sewage?—Yes.

9698. That is exactly Mr. Mansergh's process?—Yes, as regards the Crossness section.

9699. The first assumption which strikes me as important is, that the ratio between the quantity of sewage upon a particular day pouring out of the sewers, and the quantity of upland water at Teddington represents the ratio in which the two are combined

*Prof. W. C. Unwin.*

20 Feb. 1883.

in the freshwater at Crossness; that is your first assumption, is it not?—That is one of the assumptions.

9700. The first observation I have to make upon that is, why do you leave out the other upland waters?—This is a matter of detail; but I have not left out the other upland waters.

9701. But you said Teddington?—But I have left out no waters.

9702. Then that is a slip of the tongue, and I substitute for "upland waters" "all the waters coming into the river"?—There is a diagram showing how I have taken all the water.

9703. Then it is a little misunderstanding between you and me, and we will understand all the water to be coming in at Teddington; and I suppose you made the same assumption at Gravesend, or Southend, or anywhere; wherever you want to do the same thing at the lower part of the river, you make the same assumption?—It is the same thing, but I have not required to adopt the same plan there.

9704. (*Chairman.*) I think I undertand you to say that below Crossness you take in the tributaries?—Yes. Below Crossness the tributaries are expressly dealt with. Above Crossness the method used estimates them as equivalent to an equal amount of Teddington water.

9705. (*Mr. Bidder.*) I mean the same thing *mutatis mutandis*. Now does not it occur to you that the fresh water which dilutes the tide water at Crossness or Gravesend, is water which has come from Teddington many days before, to begin with?—Certainly.

9706. Although it is quite true that a certain amount of fresh water poured in at the head of the tidal section of a river must displace an equal volume past every section; that is to say, assuming that the same amount of water is put in every day at Teddington, it is true that the same amount of water must be pushed past every section of the river in 24 hours if the river is in its normal régime; but in the first place it does not follow that the water which is pushed past is that amount of fresh water, it may be mixed water?—It does follow that the same amount of fresh water must be pushed passed every section.

9707. Why is that? I am dealing with 100,000,000 cubic feet poured in every day at Teddington. 100,000,000 cubic feet must pass every section every day, but that need not be fresh water?—It is the simple mathematical law of continuity that if you take two sections of a river, the external conditions of which remain constant, the inflow at one end is equal to the outflow at the other, and further, the inflow of each material at the one end is equal to the outflow of each material at the other; otherwise the condition of the river changes.

9708. Perhaps it does; who knows it does not. Take a long passage full of people, by pushing a man in at one end, you may push out a woman at the other end?—Perfectly so. I will assume that on September 14th there is a very small quantity, 50 cubic feet, less pure water across the Crossness section than came in at Teddington, let us see what that leads to.

9809. But now you are leading me away?—I am pushing out the woman. On September 14th, suppose 50 cubic feet less water went past Crossness than came in at Teddington. Now, there is no reason why on one day rather than on another there should go past Crossness less than comes in at Teddington. If on one day 50 cubic feet less go past, then on all days less go past, and consequently, in a very short time, all the water above Crossness will be pure water.

9810. But we know that the amount of pure water which comes in at Teddington is constantly varying, and sometimes varying very violently?—Yes, that is so.

9811. Now just let me show you where your proposition would lead you, because if upon a particular day the proportion between the sewage running out of the outfalls and the upland water coming over Teddington Weir necessarily represents the proportion all the way down the river of those two constituents, sewage and fresh water, it comes to this, that if by any arrangement we were to stop the sewage, we should absolutely instantaneously purify the whole river upon that day, that must be so?—May I ask you to put that question again.

9712. If your proposition is true, that taking the amount of sewage running in upon a particular day, and the amount of upland water coming in over Teddington Weir, the ratio between those two necessarily represents the proportion in which they exist all the way down the river, then it follows that if artificially or naturally you produce a variation, by either decreasing the amount of sewage you throw into the water, or by increasing the amount of the upland water, you instantly alter it all the way down the river. I see one of the honourable Commissioners thinks I am putting a thing which is absurd, but I will show that I am putting a thing which is not only not absurd, but which actually occurs in practice. Take for instance the 29th and 30th of October according to Mr. Baldwin Latham. Of course we cannot do such a thing as to shut up the sewers for a day, but nature does a thing which is equally violent. Upon the 29th of October, Mr. Latham shows that there were 800,000 cubic feet per minute of water going over Teddington Weir, and the next day that was increased to over a million cubic feet. Now, do you mean to tell us that by that flood coming over Teddington Weir, the whole of the water of the river was changed instantaneously?—I say that there was a change at every section due to the increased displacement, and that the salt line was charged all the way down.

9713. So that the introduction of that extra 200,000 cubic feet of water at Teddington coming down in the sudden rush of a flood, instantly purified to that extent the river 50 miles away?—It instantly purified to the extent of the travel due to the upland water, the whole of that water down to Southend—that is to say, not instantly, but in the period of one tide. The effect of a larger quantity of upland water coming in at the top, is that the whole of the water is displaced down the river by so much from the top of the river to Southend.

9714. But in order to make that true, it must have displaced a great deal more upland water than actually came over Teddington Weir?—Immensely more, but I do not quite understand the point. I think I can meet that by saying that the correctness of these tables assumes that the external conditions of the river had remained constant for some period before the period of observation. As a matter of fact, the external conditions change; the quantity of upland water and the range of the tide changes, and to take into account those changes, it is necessary not to have one table of one tide, but to have several tables of several tides.

9715. Your tables assume a constant flow over Teddington Weir for a long time?—To be strictly accurate, this table assumes that the external conditions both as to Teddington water and as to range of tide, were constant.

9716. Of course you know that when you do increase at Teddington the quantity of water flowing over Teddington Weir, you do not immediately produce a corresponding increase in the section down below—you steepen the gradient of the water?—But, do you steepen the gradient of the water?

9717. Yes; do not you understand what I mean?—No, certainly not.

9718. If in a long river you suddenly introduce by flood or otherwise, a quantity of water coming over at the head of it, you do not produce a corresponding increase in the flow all the way down the river, but the first effect is to pile up the water at the head, the result of which is slightly gradually to increase the flow in each of the succeeding sections?—That is in a non-tidal river; the only mode of transmission down stream of any effect, is the material travelling down of

the water; but in a tidal river you a have a tidal wave which alters things completely. As far as I know there is no steepening of the gradient in a tidal river.

9719. But though you introduce a tidal wave as a complication, yet it is only a complication. If you increase the reception of water, the increase of discharge into the section below must be brought about by increase of head?—If you have a section where the gradient is at no two moments alike, I think it is wrong to say that the introduction of water at Teddington increases the gradient.

9720. Take London Bridge, when the tide is running out, the water is running downwards, and when the tide is coming in, the water is running inwards, and the discharge at London Bridge is the balance of the two; you cannot increase the discharge at London Bridge on the ebb unless you increase the difference of head upon the two sides of London Bridge?—I think I may admit that.

9721. And you cannot increase the difference of head upon the two sides of London Bridge until the accession of upland water has had time to do it?—You will always do it in one tide. I mean to say that the alteration of the low water gradient does not correspond to the increase of the Teddington water.

9722. Now let me pass on to another assumption, namely, the assumption that that which is once sewage is always sewage?—That is assumed for my purpose only.

9723. No account in your diagram is taken of sewage which is destroyed by decomposition?—I, a little object——

9724. Would you mind answering first, yes or no. No allowance is made or account taken in your diagram of sewage which is destroyed by decomposition?—I do not know of any destruction of sewage.

9725. You do not admit its existence, and you ignore it, if it does?—There may be a decomposition.

9726. I do not ask you to speculate as to that. I ask you what you have done—you do not admit its existence and you do not recognise its existence in your tables?—I assume that the sewage coming out at Crossness and Barking remains as a material in the river.

9727. (*Professor Williamson.*) In what sense do you use the word "sewage"—is it to describe a quantity of liquid containing things in whatever state, or containing things in a particular state?—I have said nothing about the condition of the sewage. I have only assumed that that which enters at Barking and Crossness remains in the river, with the two slight exceptions which I have named.

9728. (*Mr. Bidder.*) You take the 26,000,000 coming out at Crossness and Barking, from the tables, as being and remaining sewage to the end of your chapter?—Yes.

9729. You do not take any account of its having been purified by water and so on?—No.

9730. Now you spoke of some people believing in the river emptying and filling with the tide, but in point of fact, we have established by Mr. Mansergh, this: that the river is half filled and emptied every tide; that you admit, do you not, that the tidal section of the river, taking it from, say Southend upwards, is half filled and emptied every tide?—That the volume of tidal water which enters at any one tide is about equal to the low water volume.

9731. That is putting in a very long way, what I put very shortly. Now I ask you this, the next assumption you make is that the fresh or incoming water which is brought in by the high tide from the sea is the old sewage that went out to sea?—I should very much like that assumption to be pointed out in anything that I have said.

9732. In your section, for instance, above Crossness (I will go back to the same illustration) you give as upon the 14th of September upon Table 6, which I was at before, a certain ratio of upland water which you call Crossness water, with a certain ratio of sewage in it?—Yes.

9733. Now you know as a matter of fact, that water, salt, fresh, or sewage, or whatever you please to call it, did come from seaward of Southend, because the content of that section for the first 10 miles above Southend is just half the total content of the river, and therefore it all comes from the sea; do you follow me?—Yes.

9734. I do not know whether it exactly coincides with your first two sections, but for the first 10 miles above Southend it has all come from the sea at high water?—Yes.

9735. You find a certain proportion of salt in that?—Yes.

9736. And you infer from that, that there is a certain proportion of sewage in it?—Yes.

9737. Does not that involve your assumption which I put to you, that water which has come in from the sea, is the old fresh water and the old sewage which has gone out to sea before?—Yes, I think it does. I think I may defend that assumption.

9738. You find from the facts that Professor Way has given, if the samples are properly taken, that there is a certain proportion of chlorine above Southend which you know comes from the sea, and you assume that that fresh water which comes from the sea has exactly the same proportion of London sewage in it, as the water at Crossness opposite the outfall. Now have you investigated the condition of the river and the estuaries, seaward of Southend, so as to form any judgment as to, to what extent that assumption is partially or wholly, or to what extent right?—I have looked at that question, I find that Southend is not the end of the river, that there is still an estuary extending beyond and that into that estuary there comes at all events, one principal river which is also bringing fresh water; but I find that the drainage area of the Medway is only one-tenth that of the Thames; and it is fair to suppose that of the fresh water which there may be at any moment in that estuary, not more than one-tenth has come out of the Medway, and that, that one-tenth, whether it is as impure or not as the Thames water, does not very much affect the question.

9739. Therefore you assume, subject to a qualification of the nature you have indicated, that that must be fresh water that went out of the Thames and must contain the same proportion of sewage?—That is quite right.

9740. And therefore to carry your assumption further, that the proportion between our sewage and the upland water over Teddington Weir actually determines for the day, the proportion of sewage and fresh water there is in the sea itself?—If you mean by the "sea itself," the estuary of the Thames, I say yes, we have taken a perfectly arbitrary termination to the river.

9741. Take Margate?

(*Mr. Balfour Browne.*) Do your tables go to Margate?

(*Mr. Bidder.*) Yes they do.

(*Witness.*) I will make to Mr. Bidder this concession at once; for 10 miles up from Southend, you have water which has come in from—you do not quite know where. I have looked at the question and formed a judgment about it, I may be wrong, but any objection taken upon that ground applies only to the last 10 miles of the river's course; to the 10 miles above Southend. The water which is higher up than 10 miles from Southend, never goes out even of my part of the river at all.

9742. Where did the salt water come from up at Chiswick even, if it did not come from the sea?—It comes from St. Paul's Pier; at St. Paul's Pier, it came from Deptford, and at Deptford it came from further away.

9743. But is there a manufactory of salt at St. Paul's Pier; does not it mean that whenever you find an indication of salt by chlorine, that indicates that the salt water in the mixture must have come from the sea?—No doubt.

9744. Therefore this indicates that the water must

*Prof. W. C. Unwin.*

20 Feb. 1883.

have come from the sea?—I know no other source of water in the river beyond the Thames and Medway, except the sea.

9745. Your table stops at Southend, but Professor Way's analyses do not stop at Southend; he takes the trouble to show you that even down at Margate there was, according to your inference, something like 12 per cent. of fresh water; that is to say, if your analyses are right, upon exactly the same basis, then you ought to assume that there was 12 per cent. of fresh water, and therefore upon the same assumption a certain percentage of sewage?—I should accept the assumption that there was 12 per cent. of fresh water at Margate, and that it contained therefore a certain percentage of sewage.

(*Sir John Coode.*) It would be useful to know at what depth in the water these samples were taken at Southend and at Margate.

(*Witness.*) My point of view is that an enormous volume of fresh water goes out daily from the Thames, it may strike out into the sea, but it need not be dissipated all at once; a current of fresh water may have gone past Margate.

(*Mr. Balfour Browne.*) I am instructed that this sample was taken a foot below the surface, from the end of the jetty at Margate.

(*Sir John Coode.*) I rather suspect that what you have suggested lies at the bottom of it.

(*Mr Bidder.*) I should have preferred to pass from asking these questions now, because there must come a time at which we must ask that question as to the whole of them. Without suggesting for a moment that any of the samples were unfairly taken, yet the question must be asked as to whether they fairly represent the average of the river at these points.

9746. (*To the witness.*) Now will you give me Table No. 1, which represents the areas?—It has not been put in evidence, and I do not know whether it is fair, therefore, to ask for it, but I have no objection to hand it to you (*handing the same to the learned counsel*).

9747. Is this the same as Mr. Latham's?—I believe it is. I got it from the same source.

9748. There is Table No. 13, that we have not had?—It is really the same thing as is given in Table 14, for separate sections, but it is not printed and I have not put it in evidence.

9749. (*Chairman.*) Does such a table exist as Table 13?—I made a table which I call Table 13, but I have not used it in evidence.

9750. (*Mr. Bidder.*) Why did you not use it, did it turn out wrong?—No, Table 14 is based upon it. Table 14 gives you all that there was in Table 13, but in a better form.

9751. Now I have to ask you one or two questions upon these tables in matter of detail. Now, in dealing with these tables in regard to upland water, I am told that you rather ignored the River Lea, or brought it in at a different part of the river from where it does come in; you have treated it as coming in at Barking, is that so?—I have treated all tributaries as coming in at the next section below the one at which they come in.

9752. In Table No. 4 you have Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, and Barking. You bring in the River Lea at Barking, do you not?—I do not know the river personally to any extent, but I have treated it as coming in about Barking.

9753. May I tell you that it would come in at another part of the river between Deptford and North Woolwich?—Mr. Latham measured a large number of streamlets which I had very great difficulty in allotting.

Re-examined by Mr. Balfour Browne.

9754. You were asked whether you had made any observations upon the Thames. I believe you were at one time, in fact for a long time, occupied in making observations of the currents of the Thames, were you not?—I have made a large number of velocity observations and stream observations on the Thames.

9755. Where were they made?—They were made at Putney and in the upper part of the river.

9756. But when you turned your attention to the question of the disposal of the sewage by means of the river, this was not your first acquaintance with the Thames at all?—No, it was not.

9757. And your inspection has not been confined to the penny boat as my learned friend suggested. Now with regard to this method of calculation taken from the section areas, will you tell me exactly what you did. My learned friend says you did not adopt the right method. Will you just tell the Commission what you did?—In this particular case I have believed it most accurate to take the mean of the two sections at the end, and to multiply them by the distance.

9758. And I understand you to say you consider that under the circumstances that is the most accurate method you could adopt?—Decidedly.

9759. (*Mr. Bidder.*) May I ask you one question; were not you rather pressed for time?—I was.

9760. (*Mr. Balfour Browne.*) Is it not the fact that this method has been adopted in large engineering works in India?—It is a common enough method of calculation.

9761. What would be the effect of any error upon that method of calculation; would it tend to increase, or to diminish the area?—I cannot in the least answer that question. The sections of the river vary so irregularly, that it is impossible to predict upon which side the error would be.

9762. With regard to the discrepancy between your volume at Southend, as compared with Mr. Mansergh's, how many sections had you to calculate that from?—For the section between Gravesend and Southend, I only had two cross sections.

9763. Do you know as a fact that Mr. Mansergh had as many as nine sections?

(*Chairman.*) Even if he did know it, it would not matter; you can prove the fact for yourself.

9764. (*Mr Balfour Browne.*) We will prove the fact by putting in the sections. (*To the witness.*) Now with regard to this question, the section at Southend is the least important of all for this inquiry, is it not?—I suppose it is so.

9765. Do not suppose; is it, or is it not so?—It appears to me that the sections up the river are the more important.

9766. I understand your evidence to be that the amount of water coming in at Teddington, displaces the same amount of water in the course of one tide the way whole down the river?—The same amount of water.

9767. Is it the fact that that water must necessarily be the same amount of fresh water, or that otherwise the whole condition of the river would gradually be changed?—Yes, certainly.

9768. That is the theory you have gone upon in one of your tables?—Yes, quite so.

9769. Now with regard to the assumption that once sewage always sewage; what you have been dealing with, is not the chemical question of what becomes of the sewage, but what becomes of certain bodies?—Of what becomes of certain materials.

9770. One of the materials comes out of the sewers at Crossness and Barking, and you call that sewage?—Yes, I call that sewage.

9771. Now with reference to the fresh water coming back, I scarcely followed my learned friend, but is there the least probability that the fresh water which comes back into the Thames, is more probably Medway water than Thames water which has gone out.

(*Mr. Bidder.*) I made no suggestion of the kind.

8772. (*Mr. Balfour Browne.*) Is there any probability of that being Medway, and not Thames water?—I

suppose it is certain that a minute proportion of the Medway water does come up the Thames.

9773. But according to your evidence, the Medway is only a tenth of the size of the Thames ?—Only a tenth.

9774. And the proportion of pollution in the one, could not vary the pollution found in the other ?—It could not make any appreciable difference.

9775. So that supposing a certain proportion of the Medway water to come up the Thames, could it make any appreciable difference in the character of the water ?—No appreciable difference.

9776. (*Chairman.*) In making your ideal tide, you take a very small quantity of water as coming over Teddington Weir; did you know as a matter of fact, that so small a quantity as that ever did come over Teddington Weir ?—Yes, it agrees with what has been given by Mr. Baldwin Latham as the minimum flow of the Thames.

*Prof. W. C. Unwin.*

20 Feb. 1883.

9777. (*Mr. Bidder.*) Upon which day ?—Not any day of ganging, but he stated that in his evidence as the minimum flow. I have compared it with other matters of which I have knowledge and with gaugings which I have taken myself, and I take that as a fact which cannot be much wrong.

9778. (*Sir John Coode.*) I think Mr. Baldwin Latham said in answer to a question by myself, that he obtained those figures from the Thames Conservancy Record ?—Mr. Latham states in his report that the dry weather flow is 12 cubic feet per minute per square mile; my figure I know does not differ very greatly from that, though it may not be identically the same.

The witness withdrew.

(*Mr. Bidder.*) I have drawn my learned friend's attention to the passage in the evidence in which the sections are referred to—it is at Question 8904 Mr. Mansergh was asked, "You have given us a "certain amount of sectional areas of the river upon "the paper M 2; but you have cross sections of the "river all the way down, have you not. (*A.*) I had "134 plotted. (*Q.*) Have you any objection to pro- "ducing them all ?—(*A.*) I do not think so; my cross "sections as I explained are between something "above high water and something below low water," and then my learned friend Mr. Webster, as my learned friend reminds me, said "You shall have them "of course."

(*Mr. Balfour Browne.*) What I am instructed is that if my learned friend wants to look at what Mr. Mansergh used he is perfectly welcome to it; but if he wants us to plot them upon paper and hand in copies, I believe it would cost a very large sum of money to do it,

(*Mr. Bidder.*) I do not want to put my learned friend to any unreasonable trouble. I understood Mr. Mansergh to say they were all plotted, and all we want is to be able to have a copy of them or even to copy them ourselves—we do not want Mr. Mansergh to be at the expense and trouble of copying them.

(*Chairman.*) Do I understand you to make any application.

(*Mr. Bidder.*) I do not understand that it is necessary.

(*Mr. Balfour Browne.*) I will call the attention of my leader to it—Mr. Mansergh is not in town now-but I will bear it in mind and your attention shall be called to it again.

Mr. Peregrine Birch, called again and further examined.

(*Mr. Balfour Browne.*) When you were cross-examined by my learned friend Mr. Michael, there was a discrepancy pointed out. I do not know whether he wants to ask you any further questions.

*Mr. P. Birch.*

(*Mr. Michael.*) Not just at present.

9779. (*Mr. Balfour Browne.*) Will you explain the discrepancy ?—There was a discrepancy between the number of days in which I made it appear necessary for the sewage to pass through a certain section of five miles, and the time which appeared from Mr. Mansergh's tables to be required for it to pass through the same five miles.

9780. (*Chairman.*) Will you give us the reference; is it at Questions 9351 and 9352 ?—That had reference to the five miles below Crossness. Mr. Michael says after question No. 9351. "No; I make it that there "is about 100,000,000 difference between us." That was so, that there was about 100,000,000 difference between us.

9781. (*Chairman.*) Which is the discrepancy which you wish to explain ?—It is that as I mentioned upon the last occasion, certain of these daily divisions were calculated, and the intermediate ones were filled in without being calculated; the one was calculated, and that would be accurate—the others were filled in by the eye. The five miles happened to begin and end at certain points between the calculated points, so that a very small correction of the intermediate ones will make the difference. The division between September the 3rd and September the 2nd upon that diagram was calculated; the division opposite Erith was calculated; no other was calculated until you come to the division between the 20th and the 21st of August.

(*Mr. Michael.*) The inaccuracy did not matter as to any particular division because I have calculated every single one, but as I understood from Mr. Birch it was impossible to make them agree, because he had adopted a different principle from Mr. Mansergh. Both Mr. Mansergh and Mr. Latham had taken the quantity of water passing over Teddington Weir upon a particular day. Mr. Birch had adopted the plan of taking the mean of the quantity spread over 12 days as representing the quantity for calculation as the basis for that particular day, so that there must be a divergence.

(*Witness.*) But the discrepancy is not due to that at all. I did not take the mean of the flows at all. I took the actual flows of the days which contribute to or affect the diagram. I had nothing to do with any mean at all.

9781*a*. (*Mr. Balfour Browne.*) What does account for the discrepancy ?—The discrepancy is due to the intermediate divisions being interpolated by the eye and not accurately interpolated. If you get half a day out upon each side, that makes a difference of an addition or a deduction equal to a day's flow.

9782. (*Mr. Michael.*) But you will recollect that I added up the whole of the column and that showed a difference of at least 10 per cent. upon the whole ?—That I will explain by and by.

9783. (*Mr. Balfour Browne.*) Taking every tenth division, and comparing that with Mr. Mansergh's, there would be an absolute coincidence ?—Yes, taking these five miles. I find that by calculating an intermediate one, I make it that my total of five miles comes to 953,000,000, and Mr. Mansergh's comes to 955,000,000—those are the figures as given by Mr. Michael. I can show Mr. Michael a tracing which shows the adjustment.

9784. How do you deal with the question which my learned friend Mr. Michael has just raised, that the totals of Mr. Mansergh's columns were different from your totals ?—The total difference was not so much as 12 per cent.

(*Mr. Bidder.*) Yes, as 73 is to 82; the total of your columns added up, comes to 707,200,000, and the total of Mr. Mansergh's columns added up, comes to 825,611,870.

(*Witness.*) That is between Crossness and Southend.

(*Mr. Michael.*) Of the total divisions.

*Mr. P. Birch.*

20 Feb. 1883.

(*Witness.*) Of Mr. Mansergh's six lengths of five miles?

9785. (*Mr. Bidder.*) You both end at Southend?—Yes; but we do not both begin at Crossness. I think you will find that the 12 per cent. error is due to the column between Crossness and Southend.

(*Mr. Michael.*) No, the figures are all different.

9786. (*Mr. Balfour Browne.*) Just taking Mr. Mansergh's figures, is it the fact that he has taken a longer length of river than you have?—Yes, I find that he has divided the river into six lengths of five miles, and taken out his quantities accordingly, and I have taken the length from Crossness to Southend a little over 29½ miles, and that would no doubt make a little discrepancy, but I should say, that when I found I was within 5 or 6 per cent. of Mr. Mansergh, and that my error was favourable to the Metropolitan Board of Works, I considered that as we had arrived at the thing by two not identical processes, I had arrived at it near enough. I must emphasize the statement, that my error is in favour of the Metropolitan Board of Works; if it had been the other way, I should have taken more pains to get at the bottom of it.

9787. You took 29½ miles and Mr. Mansergh took six divisions of 5 miles each?—Yes.

(*Mr. Bidder.*) But that could not make a difference of 12 per cent.

9789. (*Mr. Balfour Browne.*) What difference would that make in the number of days in getting out to sea?—I have refined upon mine as far as ever I can. I could make it a day and a half longer; that would be the effect of the revision of all my calculations, to make it a slightly longer time going from Barking to Southend.

9789. And as you made it a day and a half shorter, that was all in favour of the Metropolitan Board of Works?—Yes; if my discrepancy had been the other side, I should have gone into it.

9790. You made it in your original calculation go out a day and a half quicker?—Yes.

*Mr. Michael* stated that he did not propose further to cross examine the witness.

(*Mr. Balfour Browne.*) Then there was a question about the floats.

(*Mr. Bidder.*) Cannot you let the unhappy floats die?

(*Chairman.*) Any question you have to put to the witness, please put it at once.

(*Mr. Michael.*) The witness was in charge of certain experiments, and he promised to procure certain information; it is not a matter of examining him now.

(*Chairman.*) Will you state whatever you have to put before us?

(*The witness handed a paper to Mr. Michael.*)

(*Witness.*) Mr. Michael put it to me, that some man of ours was supposed to have done wrong about 1 o'clock in Erith Reach, on the 16th of October. I have ascertained the name of the man, but I have not the charge that was made against him. I have seen the man and he denies all knowledge of having done anything wrong.

(*Mr. Michael.*) But I made no charge whatever. I said to Mr. Birch, "Were you in charge of these experiments"? and he replied "I was"; then I said, "Do you know the men who were employed"? and he said, "I cannot charge my memory, but if you will "give me any specific question as to any man em- "ployed upon certain occasions, I can tell you who "they were, and when they were employed." I presume Mr. Birch will now give me the information who was in charge of a certain float at a certain time and place.

9791. (*Chairman to the witness.*) Are you able to supply these names and places?—I am.

After a short discussion.

9792. (*Mr. Michael.*) The question I asked was the name of the man in charge of the float that passed down Erith Reach upon the 16th of October?—It was in charge of men named Warner and Britchler; that was No. 4 float.

9793. Were Meares and Whiting employed upon October the 17th, at 6.15 a.m.?—Yes, they were.

9794. Where were they at that time; do you know of your own knowledge?—I do not know, but I can get the information for you.

9795. Who were the men in charge of No. 6 float, near Millwall, on October the 16th?—There is no time mentioned, so that may refer to two men named Long and Hampshire, or to two men named Wright and Arnold.

9796. What time were the first two men employed upon No. 6 float, and what time of the day were the second two men employed?—Wright and Arnold were occupied the first 12 hours of the day, and Hampshire and Long the second 12 hours of the day.

9797. (*Sir John Coode.*) When you say the first 12 hours, you mean from midnight to noon I suppose?—Yes, I suppose so, but they divided their work differently.

(*The witness referred to a time sheet.*)

9798. What No. of float were Tanner and Long employed upon, on October the 29th at 5.50 a.m.?—No. 6 float.

9799. And which float were Taylor and Clements employed upon, on October 30th at 5.17 a.m.?—That was No. 1 float.

9800. (*Mr. Lumley Smith.*) To make it intelligible upon the notes, this paper upon which my learned friend has been examining you, was supplied to you since the last meeting of the Commission?—Yes.

9801. It asks you, does it not, certain definite questions as to certain men, and where they were at work?—No, it does not ask very definite questions, and that is why I took the trouble to find out things which had not been asked.

9802. No charges were made upon that paper?—No, I sent down to inqure of the men yesterday, and could not find anything of the kind.

9803. During the time the experiments were going on, was any information ever given to you by my learned friend's clients of any misfeasance on the part of the men?—Certainly not.

9804. They were a public body and they gave you no reason to be dissatisfied with your men?—No.

9805. Have you made any inquiry——

*Mr. Bidder* objected to the question.

*The Chairman* intimated that this branch of the examination was wide of the main question.

(*Mr. Lumley Smith.*) I propose to put the following questions to the witness. Have you made every inquiry with the further information which is given you by my learned friend's clients, and have you any reason to believe that there has been any misfeasance on the part of your men.

*Mr. Bidder* objected to the question.

(*Chairman.*) If it were in any way material, we should form our opinion upon the tangible evidence which came before us.

(*Mr Bidder.*) I am bound to tell my learned friend that the reason we have asked these questions in the case of these men arises from a discussion which took place upon the previous occasion. I told my learned friend then, that if he relied in any way upon these float experiments he must prove them. Mr. Birch had the general superintendence of them, but Mr. Birch could not be present upon every occasion with the floats, and if my learned friend relies upon these floats, I am bound to tell him that I shall prove at the proper time that they were doing things which they ought not to have done.

(*Chairman.*) Surely it would be time enough to make that observation when you came to make your opening speech, but still you have mentioned it, and we can deal with it if it should hereafter become necessary.

The witness withdrew.

Dr. Charles Meymott Tidy, M.A., M.B., called; examined by Mr. Lumley Smith.

*Dr. C. M. Tidy, M.A., M.B.*

20 Feb. 1883.

9806. I believe you are Professor of Chemistry and Forensic medicine at the London Hospital?—I am.

9807. I believe you hold several other offices?—I do.

9808. You have had for some years, have you not, considerable experience in Parliamentary Committees and elsewhere upon matters connected with water, and water pollution in the river Thames?—Yes, I should say I have had considerable experience.

9809. Before proceeding to matters of greater detail I am going to ask you a few general questions with regard to the composition of the water of the Thames; what will be a convenient way in your judgment of dividing the subjects? The river Thames is composed of various elements of course?—It is composed of river water pure and simple, of sewage, and of sea water, and it occurs to me as convenient to take in the first instance the character and the composition of those three classes of water, and then we can deal with them when we get to the mixture.

9810. When you speak of the Thames water pure and simple, I presume you refer to the water which comes over Teddington Weir; whether it is either really pure or simple is another question?—That is quite another question.

9811. Now what opportunity have you had of becoming acquainted with the water of the Thames which comes over Teddington Weir?—I cannot say that I know the water exactly as it comes over Teddington Weir, but I know the water of the Thames from a very long series of observations at the intake of the London Water Companies at West Moulsey, and you may fairly take that as representing, and as a matter of fact I know it does, the composition of the water as it comes over Teddington Weir.

9812. I presume you have had to make those investigations partly with regard to the supply of water to the metropolis?—Yes, I have had for many years past a sample of water taken from the middle of the river one foot from the surface upon the 15th day of each month.

9813. Then for all practical purposes we may take the water at West Moulsey as practically the same as that in the rest of the river at Teddington?—Yes, the samples extend from 1874 to 1879. I have put down in a table the quantity of matter in solution and the quantity in suspension during that period. There were a few lapses between 1874 and 1879. The reason why I have omitted certain samples is, that those samples were taken at some other period of the month, some were taken upon the 3rd of the month, and some were taken upon a later date, so I have only selected those samples only which were taken upon the 15th of the month.

(*The table was handed in and was as follows.*)

## TABLE.

Table showing Dissolved and Suspended Matters in Samples taken from the River Thames at Hampton, about one foot from the Surface, on or about the 15th day of each Month.

| — | 1874. | | 1875. | | 1876. | | 1877. | | 1878. | | 1879. | |

c. = *clear*; that is, where there is no visible suspended matter.
v.s.t. = *very slightly turbid*; that is where a few floating particles are perceptible.
s.t. = *slightly turbid.*
t. = *turbid*; that is, where the quantity of suspended matter is less than 0·1 grain per gallon.

9814. It may seem perhaps an elementary question, but what have you to consider with regard to the water; you mentioned the solid matter; that appears I presume either in solution or in suspension?—Yes, that is so.

9815. What are the divisions of what is in solution; may that again be sub-divided?—Very much so.

9816. Then what classes would the matter in solution divide into?—It may be divided of course into the organic matter and into the mineral matter.

9817. The mineral matter speaks for itself, but what do you call the organic matter?—The matter derived from vegetable or from animal substances.

9818. With regard to the matter in suspension there, I presume you get a still greater variety?—There again you have only the mineral and organic.

9819. Then shall we begin with the solid matter?—May I say, with respect to the analyses in this table, that all that was done with this water and which is recorded here was as to the dissolved matter and the suspended matter in each sample. So far as the composition of the mineral matter is concerned, that is derived from an examination of the filtered Thames water as supplied by the several companies.

9820. You have not actually filtered the sample that was sent to you?—With respect to the water that is taken from the river itself, the only two things that were estimated were the dissolved matters, and the suspended matters. With respect to the actual composition of the water, that has been the result of a a series of analyses of the filtered Thames water itself, and therefore this diagram refers simply to the quantity dissolved and the quantity of suspended matter in the samples taken a foot from the surface, upon the 15th of each month; but the composition of the water in greater detail refers to the other samples as well. Now during these years from 1874 to 1879, the suspended matters in the water of the Thames were estimated upon 59 different occasions; on eight occasions the water was found perfectly clear; on seven occasions it was found "very slightly turbid"; what that really means is, that one sees minute particles but you cannot estimate it. On five occasions it was noted as "slightly turbid;" those of course are arbitrary terms, but the latter means something that appears to me more than "very slightly turbid." Then on 11 occasions it was found to be turbid, and I think I may say this, that when the water is marked as "turbid" it contains less than, or somewhere about one-tenth of a grain of suspended matter per gallon. Upon eight occasions it was found to contain less than a quarter of a grain of suspended matter per

*Dr. C. M. Tidy, M.A., M.B.*

20 Feb. 1883.

gallon; that is to say, between a tenth and a quarter; upon six occasions it was found to contain between a quarter and a half a grain per gallon; upon five occasions between a half and three-fourths; on three occasions between three and a quarter and one grain; and on seven occasions above one grain of suspended matter per gallon. The analyses were not continued for this purpose after the year 1879, and therefore I am not able to give you any further details.

9821. What do you say as to the average of the river with regard to the suspended matter; first of all does it vary much with the time of year?—It does vary a good deal according to the quantity of flood water; but the point which this table seems to suggest is, that the quantity of suspended matter in the River Thames above Teddington, that is to say, the water taken at Moulsey is exceedingly small, and that as a matter of fact, the turbidity of the water may be due to an almost inappreciably small quantity of suspended matter. It is wonderful the very small quantity of suspended matter that will make the water appear perfectly turbid.

9822. Then practically you give the water a good character?—Yes, I give the water a good character as as far as the suspended matter is concerned.

9823. Now taking the soluble matter, that is to say, matter in solution, will you give the quantities?—The total solid matter in solution in Thames water varies from 17 to 22 grains per gallon, occasionally it is a little below 17 grains per gallon, but I never knew it below 16 grains per gallon, and in the other extreme, it is occasionally a little above 22 grains per gallon, but not above 23 grains, so that practically the extreme limits may be taken as from 16 to 23.

9824. Do you find that that varies at different times of the year?—Yes, it does. The quantity of dissolved matter in the water of the River Thames shows a perfectly well defined wave in the course of the year.

9825. At what time of the year do you find that there is the greatest quantity?—It always reaches its maximum, that is to say, the crest of the wave occurs about February.

9826. (*Mr. Bidder.*) Your highest is marked in December?—Those are the actual numbers. I am taking now the average of a very large number of experiments, you only get the wave properly by taking a very large number of experiments. I am speaking of the dissolved matter in filtered water.

9827. (*Mr. Lumley Smith.*) Have you worked this table from the filtered water?—I have worked this table from the filtered water entirely.

9828. As my learned friend Mr. Bidder points out, you do find on one occasion as much as 24·30?—That is the unfiltered water.

9829. When you are telling us about your general conclusions, those are derived from the filtered water?—Yes, the water of the water companies.

9830. But you say you find your highest amount of dissolved matter is in February?—Yes, and the smallest amount invaribly occurs in August taking a very large number of results, it forms a perfect wave from February to August, and then from August to February; that is to say, the dissolved matter in filtered water.

9831. I presume the same law would apply very much to unfiltered water?—Yes, in a great measure, but there is something taken out by filtration beyond the mere suspended matter.

9832. For our purposes we shall have to deal with the actual water rather than the filtered water?—Yes.

9833. This table you have here is taken from the actual water of the river unfiltered?—Yes, when the suspended matter has been allowed to deposit, and then the clear water has been syphoned off and the total solid matter estimated.

9834. Now with regard to the chlorine found in the river, what may that be taken at broadly?—In the Thames, as the result of a very large number of observations, it may be said that one grain of chlorine per gallon is the normal quantity. It may be taken that from February to August, the quantity of chlorine in the river is about one-tenth above one grain, and from September to January one-tenth below one grain per gallon.

9835. Then roughly the quantity may be taken as rather more than a tenth of a grain per gallon from February to August?—Yes; and from September to January a tenth of a grain less than a grain.

9836. What is the presence of chlorine due to, because there is no sea water up there?—It is very difficult to say, all river water, indeed all water contains a certain small quantity of chlorine.

9837. Is that common salt?—Yes, it is there as common salt.

9838. We have now dealt with matter in suspension and matter in solution, would you now come to the organic matter, which is a sub-division of either I presume?—It is part of the solid matter of water, that is to say, when you speak of matter in solution, that means both the organic and the mineral.

9839. For the purpose of considering the purity of the Thames water, is it necessary to consider the mineral matter?—I do not think it is important, or rather I should say not the general constituents. The chlorine is important undoubtedly, and the total solid matter is important, and the magnesium is of a certain importance.

840. With regard to the organic matter, that is important, is it not?—Yes.

9841. What can you tell us about the organic matter in the Thames water at Teddington?—I have been working with Dr. Frankland in this matter, and I have quite agreed with him that it was advisable to adopt one method of examination throughout, and I am equally convinced that the only mode by which we could have estimated the organic matter in the water, is by the process which he himself suggested—the combustion process—that is to say, by the estimation of the organic carbon and of the organic nitrogen in the water. I am perfectly conviced in my own mind that it is the only process which in this special case would have give us accurate results.

9842. If that is a process which has been arrived at after consideration by Dr. Frankland, would it be desirable to describe a little more in detail what you did?—I scarcely think it is necessary, though I should be very happy to do so, but I would say that having myself suggested the process of estimating the oxygen required to oxidize the organic matter, it would seem strange that one had not introduced that into one's tables. The process is not applicable with so large a quantity of chloride of magnesium as one had to deal with in this special water where we have a large quantity of sea water, so for that reason I have not adopted it in these tables. The second process as regards albumenoid ammonia as it is called, is I am quite certain, a process which gives no results upon which one can rely in any way, therefore one was thrown back upon what I believe to be the only process which was applicable in this special case, and that was by the actual combustion of the residue, and the estimation of the organic carbon and the nitrogen.

9843. Which order would you take them in first, the organic carbon or the nitrogen?—I do not think it would make very much difference in this reach of the river in considering the normal character of the Thames water. I would say that the total quantity of the organic matter varies somewhat with the time of year; manifestly as we should have expected. For instance taking the year 1881, (and the same thing is practically true of 1882, but I have worked out the year 1881,) the organic carbon in the river water varied from ·072 to ·256 grains per gallon. Then the second point, which s very important, is the ratio of the nitrogen to the carbon, because, whilst the total quantity of the organic carbon and nitrogen indicates the total quantity of organic matter present, the ratio of the nitrogen to the carbon indicates somewhat the kind of organic matter present, that is to say, whether it is of animal or vegetable origin. Taking the normal

Thames water, it may be said that the ratio of nitrogen to carbon is about one to eight.

9844. Do you find that at all times of the year, or does it vary?—It varies somewhat; the variation would not be very great, but generally speaking it is as nearly as possible between say from 1 to $7\frac{1}{2}$ and 1 to $8\frac{1}{2}$. Then as regards the proportion of ammonia which is present in the Thames water, the quantity is very small indeed; I am speaking now of the water above Teddington. In the majority of the samples of the water there is none at all. Then sometimes one finds the thousandth of a grain, sometimes two thousandths of a grain, but the quantity of ammonia which is found in normal Thames water is for all practical purposes, nil.

9845. But does the ammonia come from the organic matter?—Yes.

9846. Speaking as an unscientific person, organic matter is a thing to be deprecated in water, is it not?—It very much depends upon the kind of organic matter. I do not know that there is any evidence to show that organic matter of a peaty origin is in the slightest degree injurious. For instance, in the Shannon, one of the purest rivers in the world, we find a considerable quantity of organic matter derived from the Irish peat bogs, but there we have a very low ratio of carbon to nitrogen, and there is no evidence to show that it is in the slightest degree injurious.

9847. (*Professor Williamson.*) I presume you have tested the water for nitrates as well as for ammonia?—I have.

9848. With what result?—I do not know that I can give it you at the instant, but I think it may be taken at from two-tenths to three-tenths of a grain of nitrogen as nitrates per gallon. Then another thing which will have a good deal of bearing upon our case is the question of the free oxygen in solution—the dissolved oxygen. One may say that it is only lately that we have had a practically easy method of estimating this dissolved oxygen, but for the last two years, I made seven determinations every day of the free oxygen in solution in the water of the Thames supplied to London. It varies somewhat according to the time of year; in other words according to the temperature. It is sometimes as low as one and seven-tenths of a cubic inch per gallon; but it may be said generally that the water of the Thames contains two cubic inches of free oxygen per gallon. It is sometimes 2·2, it sometimes goes down to 1·9, and even to 1·8 of free oxygen per gallon.

9849. (*Dr. Stevenson.*) Is that the filtered or the actual water of the river?—It varies very little indeed.

9850. (*Mr. Lumley Smith.*) I do not know whether you could tell me how many cubic inches there are in a gallon?—277.

9851. And you say there are about two cubic inches of free oxygen to a gallon?—Two cubic inches of oxygen at the standard temperature and pressure.

9852. Will you tell us what are the good and bad elements in the water. You told us with regard to your organic matter that they depended upon what it was; but with regard to the proportion of nitrogen to carbon, which of those elements in excess is pernicious, or what is the normal condition of purity, can you tell us that?—One can say this, that when the ratio of nitrogen to carbon increases, and one gets a very large quantity of nitrogen, it indicates animal rather than vegetable contamination, and so far as injury is concerned, undoubtedly, facts show that animal contamination is infinitely more dangerous than vegetable contamination, and that therefore the larger the ratio of nitrogen to carbon, the more polluted the water becomes.

9853. You get either nitrogen or carbon from animal or vegetable matter, but you get it in an increased proportion from animal matter?—Yes.

9854. Have you any remark to make as to the solid matter in solution in the upper Thames water?—No, nothing beyond what I have said. I would say, speaking about the Thames water, that the composition of the Thames water in the upper reaches above Teddington is fairly constant; I might say singularly constant, and I think it indicates water of a very considerable degree of purity. I would say about the suspended matter of the water, that the suspended matter of the water in the higher reaches is almost entirely of the nature of clay and of sand; it is nearly always clay and sand mixed with occasional particles of vegetable matter or fibre. It is a matter of fact that the suspended matter which is found in the higher reaches has a specific gravity of about $2\frac{1}{2}$; it is very finely divided, and is very long retained in suspension, but it may be taken to be of that composition as nearly as possible.

9855. It remains suspended a considerable time you say?—Yes, and although a thing may have a high specific gravity, if you sub-divide it, it does remain in suspension a considerable time, as Professor Faraday found when he sub-divided gold.

9856. Is there anything else which you wished to say with reference to the water above Teddington?—No, that is all I have to say about that.

9857. (*Dr. Francois de Chaumont.*) How do you determine the quantity of free oxygen in the water?—The quantity of oxygen in the water is determined by a modification of Schutzenberger's process; every tenth determination that we made for nearly two years was done actually in addition, in order to see how far it corresponded.

*Dr. C. M. Tidy, M.A., M.B.*

20 Feb. 1883.

Adjourned to to-morrow at half-past 12 o'clock.

---

# TWENTY-FOURTH DAY.

## Wednesday, 21st February 1883.

PRESENT:

SIR P. BENSON MAXWELL, IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.

WILLIAM POLE, ESQ., F.R.S., *Secretary.*

DR. CHARLES MEYMOTT TIDY, M.A., M.B., further examined.

21 Feb. 1883.

9858. (*Mr. Lumley Smith.*) You gave us yesterday your account of the upper Thames water, and I propose now to ask you some questions with regard to the sea water and the sewage, but before I come to that I notice that in what we are coming to you have given your quantities of carbon and nitrogen in parts per 100,000?—That is so.

9859. You gave it us yesterday in grains per gallon,

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

and it may be convenient that you should give us, if you can, with regard to the Thames water, what is the quantity of carbon and nitrogen per 100,000 parts?—I will. The organic carbon varies from ·103 to ·364 in the 100,000 parts. I think, myself, that the ·364 is rather high, but still it does vary between those numbers.

9860. And the nitrogen is an eighth of that?—The nitrogen is an eighth of that.

9861. I believe you mentioned yesterday that the suspended matter formed a wave?—The total solid matter. I would just say that I have here a diagram which gives the average results of something like 1,200 analyses of the filtered Thames water. It shows that the highest point, that is where the total solid matter is at its maximum is in February; it gradually decreases in a perfectly regular wave to August, and then it goes up again to February, so that the total solid matter in normal Thames water is one complete wave every year.

9862. Now we will pass if you please to the sea water, we will take that before we deal with the sewage, we have the Thames water at one end of the river, and now we will go to the sea water which we meet with at the other end?—The composition of sea water has been examined by us lately upon a great many occasions. (*The Witness here handed in a collection of Tables and Diagrams. See Appendix A.G.*) The results which have been arrived at by us confirm almost entirely those which have been arrived at by the Rivers Pollution Commission, and mentioned in their Sixth report.

9863. Can you give us the reference to that?—I cannot at the moment, because I have not the Sixth report with me, but I dare say Dr. Frankland can. Many of these samples were taken by myself, some were forwarded, and there is one which I have put in of the Dead Sea which is interesting in itself, which I did not take myself, but which is well authenticated.

9864. The curiosity in that case is, is it not, that the nitrogen actually exceeds the carbon?—Yes, the great peculiarity to be noticed first of all with regard to the organic matter in sea water is, the very large quantity of nitrogen that it contains, that is to say, the ratio of the nitrogen to the carbon. Thus out of these 15 analyses, in three the organic nitrogen was in actual excess of the organic carbon. That occurs, for instance, in the Dead Sea to a most remarkable degree; we have ·3 parts in 100,000 of organic carbon and ·4 of organic nitrogen.

9865. You told us yesterday that in Thames water the nitrogen is one eighth of the carbon?—Yes.

9866. In all sea water, the nitrogen is at a very much higher ratio?—A very much higher ratio, it may be taken at somewhere about one to one-and-a-half. The fact is, that in sea water, when the organic matter gets into the sea, the carbon is far more easily oxidized than the nitrogen, and as the result of that, the oxygen gets concentrated on the carbon. It is not by any excess of the nitrogen, but it is by a decrease of the carbon.

9867. You mentioned that in some of the sea water near the Thames, the nitrogen was in excess of the carbon?—That is so.

9868. You find that, do you not, at Southend?—Yes, I find that at Southend. At low water on October 16th, the organic nitrogen was higher than the organic carbon.

9869. And also on one occasion in June?—On one occasion at high water in June at Southend, the same thing occurred. The next thing to be noted in sea water is that there is very little ammonia indeed, it may be taken in many samples as none at all, sometimes there is a 1,000th of a grain, sometimes 2,000th of a grain, and in one case only did I find a 100th of a grain of ammonia.

9870. You have told us that in the upper Thames water the ammonia is nearly nil?—Nearly nil.

9871. And in sea water it is also nearly nil?—Yes, in sea water also it is nearly nil.

9872. That will be of importance when you come to try to trace the sewage?—It will; the question of the ammonia will become an important one. Then another thing to be noted is the very small quantity of nitrogen as nitrates in sea water. Then there is another point to be referred to, and that is the quantity of free oxygen; it was not estimated in those samples; except in two of them in which it was estimated, but I examined the free oxygen in sea water daily, and sometimes more frequently for more than a month off the west pier at Brighton; as a matter of fact, there were over 50 determinations, and the quantity of free oxygen in the sea water there varied from 1·7 cubic inches to 2·1 cubic inches per gallon of free oxygen in solution; therefore, as a matter of fact, the sea water that spot agrees with river water in this, that it is well taken at oxidised. There was a case at Margate where it was found to be 1·656.

9873. That is the only one you have here?—Yes, the only one I have here.

9874. Comparing fresh water with sea water, we find that as to ammonia they are pretty much the same. As to nitrogen, there is an increase in the quantity of nitrogen in sea water. As to free oxygen in solution, it is pretty much the same, except that in sea water it is rather less.

9875. (*Dr. Stevenson.*) Do you mean that there is an absolute increase of organic nitrogen, or a relative increase?—A relative increase; it is the ratio that is altered.

9876. (*Mr. Lumley Smith.*) Now with regard to the chlorine, what have you to say?—With regard to chlorine there is no doubt that it varies considerably. I have given the proportions in the table of the chlorine found at different places, perhaps the Southend samples are the ones that are more especially interesting in connection with this case; they vary from 1,246 grains at low water, on October 16th to 1,558 grains at high water upon June 10th.

9877. What do you observe from that?—One finds that in nearly all the samples the total quantity of solid matter, and the total quantity of chlorine is greater at high water than at low water. There is an exception to that, and I really cannot explain it, in the case of Brighton in September 1882.

9878. I think that concludes, does it not, what you are going to tell us about the sea water?—I think that is all I have to say about that.

9879. We will pass on to the sewage—tell us first of all, if you please, what amount of matter in solution you find in the London sewage, what sewage are you taking for this purpose?—It appears to me impossible to compare the sewage of other places with London sewage, and therefore seeing what differences there are in various kinds of sewage, the only question of interest in this inquiry is London sewage, and not any other kind of sewage; therefore I limit myself entirely to London sewage, which I think will be more convenient. I do that because I regard sewage as a very complex body, varying according to the habits of people, that is to say, according to the kind of work that is done, the trade and manufacture that is carried on; varying also with the time of year and time of day and so on; but it appears to me that the only fair way to regard the question of sewage is to take a large number of samples of London sewage as the basis of comparison; but even then I must admit the difficulty. To begin with, I have looked up a very large number of experiments which were made, and in as much as I was engaged upon them myself during the time I was assistant to Dr. Letheby, I may refer to them. I have here the analysis of a gallon of sewage taken from ten of the large City sewers, I cannot give the precise places, but they were ten of the large City sewers, the average flow at midday from which is marked as 3,490 gallons per minute. It was during the time I was assisting Dr. Letheby as medical officer of health to the city, that those were taken.

9880. (*Mr. Bidder.*) During what year?— They were before the year 1875. Now taking mid-day sewage, there was an average of 94 grains of solid matter per gallon of which 56 grains were in solution

and 38·15 grains in suspension, of that 94 grains, 31 grains were organic, 15 grains of that organic matter were in solution, and 16 grains in suspension. Night sewage, again, varied somewhat from the day sewage, it did not contain so much matter in suspension ; and again storm sewage varied from both. Taking the general proportion of suspended matter in ordinary sewage, I think it is fair to say it contains about 25 grains per gallon of suspended matter.

9881. Is that London sewage ?—Yes, but that 25 grains does not include storm sewage, because it has been clearly shown, and I know it of my own knowledge, that storm sewage often contains an enormous quantity of suspended matter. I would just say that Dr. Frankland and myself have found over 100 grains of suspended matter in a gallon of storm sewage, and that the Chemist of the Metropolitan Board of Works upon the last inquiry, that is to say in the mud inquiry, gave evidence to the effect that he had found over 95 grains, if I remember rightly, per gallon of suspended matter in storm sewage.

9882. (*Mr. Lumley Smith.*) What do you take the ordinary average quantity to be ?—It is a very difficult thing to say what you get as the average, but taking the average of one's own results with the results obtained by the Rivers Pollution Commission, one finds they very closely agree ; and I would say, putting all storm sewage and other sewage together, from 45 to 50 grains per gallon would not be an excessive amount of suspended matter, that is taking into consideration the 95 grains per gallon which Mr. Keates found, and we have found over 100 grains per gallon, and some samples recorded by the Rivers Pollution Commission are much higher than that ; so I venture to think that if you take all sewage together, day sewage, night sewage, strong sewage, and weak sewage, something like that quantity would express fairly what the suspended matter of the sewage is.

9883. (*Dr. Stevenson.*) By the 25 grains you spoke of, do you mean exclusive of the storm sewage ?—Yes, exclusive of the storm sewage. I take it that as the normal quantity from 23 to 25 grains may fairly be put down ; but taking all the rest of the year I doubt if it would come out at less than from 45 to 50.

9884. (*Chairman.*) That would include the storm sewage ?—Yes. In the report of the Rivers Pollution Commission we have a sample containing 164 grains per gallon, and I have myself found more than that, so I do not think we are taking an excessive quantity. The average of the samples given by the Rivers Pollution Commission is 48·5 grains, and when you take that an conjunction with Mr. Keates' experiments upon the A. B. C. process and in conjunction with one's own experiments, I do not think that from 45 to 50 grains on the whole is at all an excessive estimate.

9885. Is the storm sewage the same as other sewage ?—There is a great deal more mineral matter in it. I think the reason why the storm sewage contains so much more suspended matter than other sewage is, that there is always the road washing brought down in large quantities, and there is also a large quantity of matter which has accumulated in the pipes which is dislodged by the flow.

9886. It is scoured out ?—Yes. Then as regards the composition of ordinary London sewage—

9887. (*Mr. Lumley Smith*). Are you going now to the quantity of grains of matter which go into the Thames ?—I am going now to the composition of London sewage.

9888. Is that more germane to the suspended matter than the matter in solution, or would you give us the figures of the matter in solution before you come to that ?—I have very little more to say about the matter in suspension than what I have said, I think I have said all that is necessary. Now as regards the matter in solution, the strength of sewage will vary very much according to the time of the day ; for instance, there is a time when it is strong, and there is a time when it is weak, but as regards the organic carbon and the organic nitrogen as an index of the organic matter, the organic carbon as a rule as a maximum is about 5·4 per 100,000 parts, and as a minimum 3. I think you may take it that our results give about 4·3 as the average organic carbon in 100,000 parts. The organic nitrogen ranges from about 3·8 to 1·3 and about 2·5 may be taken as the average of organic nitrogen per 100,000 parts.

9889. You have given it in parts per 100,000 ?—In the organic nitrogen and carbon, I have taken it in parts per 100,000, and in all other cases at grains per gallon.

9890. Then the ratio of nitrogen to carbon is as 1 to 1·77 ?—Yes.

9,891. That is very different from what you find in the pure water ?—It is very different.

9892. It is more like what you get in sea water ?—Yes, it is more like that.

9893. Now we come to the ammonia ?—The quantity of ammonia in sewage is large ; it varies from about 6½ grains to about 2½ grains. I give organic carbon and organic nitrogen in every case in parts per 100,000, all the other results I give in grains per gallon.

9894. (*Mr. Bidder.*) It would have been much more simple if you had adopted one uniform plan ?—I have always adopted this plan, taking the organic carbon and the organic nitrogen in parts per 100,000, and all the other results ; as I have just stated, in grains per gallon ; now I think you may say that 6 grains of ammonia per gallon is the extreme number, and that about 3 grains of ammonia per gallon is the average of a large number of samples, it is not the mean of those two numbers, but a fair average of a large number of samples.

9895. (*Mr. Lumley Smith.*) That is grains per gallon ?—Yes.

9896. Now take the chlorine ?—The proportion of chlorine varies, but I think that from 10 to 11 grains of chlorine per gallon is the average of the chlorine in London sewage ; it does vary. I quite admit that you get quantities higher than that, and quantities lower, but I really think that from 10 to 11 grains is a fair average.

9897. Might I pause for a moment to make this general observation ; where you want to detect sewage in a mixture of pure water, sea water, and sewage, the only thing that seems peculiar to the sewage is the ammonia ?—The ammonia is decidedly one of the chief things.

9898. The increased ratio of the nitrogen and and carbon is common both to sewage and sea water ?—That is so.

9899. But the one thing that seems peculiar to the sewage is the ammonia ?—There is one thing which I will point out hereafter, and that is the quantity of free oxygen dissolved. It would be convenient to take that afterwards, as I shall have a great deal to say about that. I should like to add that it appears to me, as far as I can make out, that about 80 per cent. of the London sewage is represented by the water supply.

9900. (*Dr. De Chaumont.*) In the tables before us of the London sewage, the chlorine has been taken at 10 parts per 100,000, the quantity you have given us is somewhat above that ?—I think, in point of fact, the quantity of chlorine, though it varies considerably, yet it very often does reach 10 parts of 100,000, but that really makes very little difference.

9901. (*Mr. Lumley Smith.*) You were going to tell us something about the composition of the London sewage, and what went into the Thames ?—I was going to say that about 80 per cent. of the London sewage appears to me to be represented by the water supply, that is to say, if you take about 37 gallons per head as being the water supply, that would represent about 80 per cent. of the sewage ; it is 10 parts per 100,000.

9902. (*Dr. Stevenson.*) Is that your own observation, or are you taking the figures from others ?—It is my own observation, and it is not alone mine but it agrees with the observations of the Rivers Pollution Commission.

9903. (*Mr. Lumley Smith.*) You have made some

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

observations, have you not, as to the quantity of polluting matter that went into the Thames?—I thought it very important to get some idea of the quantity of polluting matter that went into the Thames, and I have endeavoured to get that as far as I can.

9904. Will you tell us your process?—I take first of all the fæcal matter that goes in, and see the quantity of that, and secondly the urine that goes in, and here I am depending upon others calculations, the calculations of Röder and Eickhorn; they are two great German authoritities, who calculate that every 100,000 people consist of 37,610 men, 34,630 women, 14,060 boys, and 13,700 girls. Now these were the first estimates made of the quantity of fæcal matter passed by 100,000 persons. There have been a good many investigations since then as to English people, and they agree very nearly although not absolutely with these. It may be said from a large number of experiments, that every person, regarding them as made up of men, women, boys, and girls, voids about 1,750 grains of fæces daily, that is a quarter of a pound.

9905. Does this include fœces and urine?—No, we are taking fœces alone, that is one quarter of a pound of fæcal matter daily. Now of that 75 or nearly 75 per cent. is moisture, so that it may be taken that the dry matter voided daily per head of the population is about 1 oz.

9906. (*Chairman.*) Is that avoirdupois?—Yes, avoirdupois. Now taking the population as 4,000,000 of people drained, it follows that the moist fæcal matter discharged daily into the Thames is 444 tons, and that the dry fœcal matter is exactly 111·6 tons, that is that every day there is about from 444 to 445 tons of fæcal matter discharged into the river at Crossness and Barking alone from the 4,000,000 of population. Now of that 111·6 tons of dry fœcal matter a little over 11 per cent., but just about 11 per cent., is soluble in water, so that it may be said that of that 111·6 tons something like a hundred and a half tons is insoluble and about 11 tons soluble.

9907. That hundred and a half tons of matter which is not soluble every day goes into the Thames, and must go somewhere, it must either be deposited or go out to sea?—That is so, so that we have a total quantity of 445 tons, we have the dry matter at 111·6 tons, and of that 111·6 tons you may take 100·5 tons as being insoluble, and that is every day. Now about the urine, the estimations of Messrs. Röder and Eickhorn on the urine passed from the 100,000 people very nearly agree with all other calculations, and according to their estimate, we have the quantity of urine passed per annum by 4,000,000 people as equivalent to 376,605,555 gallons, which is discharged into the river annually, which is equal to 1,681,274·8 tons per annum.

9908. You did not give us the moist fæces per annum, you gave it us per day; what is the figure per year?—It is 40,374 tons annually, that is the dry material.

9909. And the moist will be four times that, that is roundly 160,000 tons?—Yes; now it may be said that the dry solid matter of the urine per head of the population is as nearly as possible $2\frac{1}{2}$ ounces, and that brings it to the $3\frac{1}{2}$ ounces of solid matter discharged per head daily, which was given by Mr. Baldwin Latham; that is to say, the urine contains $2\frac{1}{2}$ ounces of solid matter, and the fœcal matter 1 ounce.

9910. (*Mr. Bidder.*) But part of that is in solution?—It is in solution but it is solid matter all the same.

(*Mr. Bidder.*) Except that what Mr. Baldwin Latham gave was in suspension.

(*Witness.*) Now this $2\frac{1}{2}$ ounces is made up of about one half of urea, and the other half of extractive and pigment and the mucus and of salts, now from that it follows that every day 4,000,000 people by their urine alone contribute to the pollution of the river 282 tons of polluting matter in addition; so that putting all that together we have daily contributed to the river $3\frac{1}{2}$ ounces per head of polluting matter, or taking the population at 4,000,000 we have 393·9 tons of matter thrown into the river daily, of which 100·5 tons are insoluble and 293·4 are soluble. That goes into the river every day, and that is an equivalent, I may say, to 143,591 tons of solid filth per year thrown into the river Thames absolutely undefecated or unpurified in any way, form, or kind.

9911. (*Mr. Lumley Smith.*) Now is the figure which you have last given soluble or insoluble?—That is everything.

9912. That includes what afterwards goes into solution?—That includes all; it is the total solid matter that I have given. Then it is important to note that that estimate does not include the other matters which make up sewage, such as the washing of public thoroughfare, the filth of kitchens, and of laundries, and the drainage of stables; and then we have to remember that every cow passes a quantity of urine containing a quantity of polluting matter 13 times as great as human urine, and every horse 20 times, it includes none of those things; markets, slaughter-houses, all trades and everything else would be in addition to the amount which I have given of something like 400 tons every day thrown into the river Thames.

9913. (*Dr. Stevenson.*) Have you any idea of how many cows and horses there are in London?—I have no idea; I only say that my calculations, take no cognisance of any of these things. Of horses there would be a very large number.

9914. (*Mr. Lumley Smith.*) Now with regard to the solid matter which goes into the Thames and which never becomes soluble, because we have heard it oscillates backwards and forwards for a time and then deposits, is there likely to be any chemical action with regard to that solid matter or what becomes of it in your view?—The insoluble matter which goes into the river floats about.

9915. In it likely to combine with anything?—Yes; it no doubt combines with alluminous compounds from the alluvial mud that would be raised by the tides and by passing steamers, and so no doubt would be carried to the bottom; I think the insoluble matter a very serious source of nuisance in the river Thames.

9916. Let us hear your view about the matter?—Because it undergoes putrefaction, and it is in putrefactive decomposition that we get a true nuisance. In the case of oxidation we do not get much nuisance, the products are not offensive, it is in the putrefaction where we get the nuisance.

9917. What is the state of the sewage which gets to the bottom?—It undergoes putrefaction as I have stated; the gases of putrefaction render it specially lighter, and as steamers come by it is stirred up, the gas is given off and down it goes again; then it putrefies again and the process is resumed.

9918. There is a certain amount of oxidation, is there not, due to its coming to the surface?—But it is owing to putrefactive decomposition that a nuisance arises. When it goes to the bottom the putrefactive gases develop, and then the stuff rises and you have the putrefactive and offensive gases given off to the air.

9919. And having risen to the surface and given off putrefactive gases, what happens to it?—Then, as I have stated, it sinks again, being weighted down again by the mud in suspension, and having putrefied again, is again stirred up by steamers as I have described.

9920. With regard to the soluble matter what have you to say?—That no doubt undergoes a series of changes; it undergoes oxidation as far as it can.

9921. Does that render the amount of oxygen in pure water a matter of any importance?—Yes; that is what we shall come to in the tables.

9922. As you find the quantity of oxygen diminish, so you find a less purifying power in the water?—Yes, the quantity of oxygen dissolved is an index of the purifying power of the water.

9923. Have you finished now what you proposed to tell us about the component parts of the sewage?—Yes.

9924. We will go then next first of all to the general inspection of the river. I am coming now to the matter which you have seen yourself with regard to the sewage, will you tell us what opportunity you have had of seeing what comes from the outfalls?—I have been on the river a great many times.

9925. Have you ever seen the sewage coming out of the outfalls?—Yes, I remember one occasion very definitely, it was on a very cold frosty morning, it was the 15th of November 1879 to fix the date Dr. Frankland and myself were on the river, when we saw a rapid stream of sewage which we calculated, or rather Dr. Frankland calculated, at something like from 20 to 30 million gallons flowing over the apron of the northern outfall at dead low water. The entire volume of the sewage as it came over owing to the amount of steam given off into the cold atmosphere looked boiling hot. We noticed from the bed of the river a bubbling up of gases, indicative of the most active putrefaction, and the smell that was given off was exceedingly foul. We noticed a similar thing going on on the same day even in Barking Reach. Such a condition as we noticed upon that one occasion on the 15th of November could only point to contamination with comparatively recent sewage undergoing decomposition.

9926. With regard to the bubbling up of gases, would that indicate putrefaction?—Yes.

9927. Sewage takes some little time to go from London to the outfalls, how soon in your judgment would putrefaction begin?—That I think is a very difficult question to answer, it has a long way to travel before it gets to the outfalls; I should not like to bind myself, but I think I should be within bounds when I say nine miles. And moreover sewage contains within itself a series of bodies of different degrees of putrescence, so that you would have putrefaction going on, and then you will have a point where putrefaction will stop; then a new series of bodies will begin to putrefy, and you will have again a point at which it will stop. You will therefore get different degrees of putrefaction depending upon the kind of body that is putrefied, so that a great deal will depend upon temperature, upon the rate it travels, upon the distance it travels, and so on; consequently I do not think I should be able to give an answer to that question in the way that I should wish.

9928. But I understand you to say the bubbling up of gas means putrefaction?—Yes.

9929. And that you say you saw going on at Barking Reach upon that day?—Yes, I am convinced from my inspections of the river upon that and upon other occasions that under certain conditions of water and under certain conditions of tide and so on a very great nuisance exists undoubtedly.

9930. With regard to the temperature, are you able to tell us anything about the degree of temperature that is required to cause putrefaction?—I do not think I could say exactly, because owing to the different kinds of putresible matters present they are influenced by different degrees of temperature.

9931. Now you have divided the river into lengths, I think, and I believe you take the first length from Teddington to Purfleet?—Yes. I would say that I thought it desirable to get a notion of the general composition of the river at different points from Teddington downwards, and therefore I thought it best to take a large number of samples at different parts of the river, those samples were taken, and now I will put them in as a diagram. (*See Appendix A.G.*)

9932. The majority of those samples were taken by yourself, I believe?—They were all taken by myself except two, namely, 35*a* and 44, those I think will be proved by somebody else, they were all taken I would say in the middle of the river a foot below the surface. I think it right to say where this table fails, because I am quite aware that there are imperfections in it. The samples were taken at the parts of the river indicated at different states of the tide. I would have much preferred to have taken all them at the same state of the tide, but that was impossible, so I have had them taken as they are at different states of the tide, they were all taken at a foot below the surface so as to avoid any impurities that were floating upon the surface. A bottle is lowered at the end of a pole a foot below the surface, and then the water is let in. Now, I have, in order to make this diagram clear, arranged it in the form of a wave (*handing in a diagram*). In addition to that, in order to get a notion of the state of the water at Chiswick it will be convenient for me to put in all these tables before I commence. I have a series of samples of water collected at Chiswick at different times of the day.

9933. You have adopted the same plan as you adopted before of taking grains per gallon except in the case of the organic carbon and organic nitrogen, and those you have given in parts per 100,000?—Yes. Now in order to see how you can systematise a large body of facts, I have arranged them in different sections, which I have also put in the form of a table, and as those are all connected with one thing, I will hand them in at once (*See Appendix A.G.*)

9934. You have taken five lengths of the river, from Teddington to Battersea; from Vauxhall Bridge to Deptford; from Greenwich to the Royal Albert Dock; then from Beckton to Crossness; and then from Erith to Purfleet. Now with regard to the diagram, all the results are stated in grains per gallon except the organic carbon and the organic nitrogen, which are stated at parts per 100,000, and the free oxygen, which is stated in cubic inches per gallon. I see at the top and bottom of your diagram A, there are certain numbers from 1 to 58?—Yes.

9935. Do those Nos. 1 to 58 correspond with the 58 Nos. on your first table that you have handed in of your analyses of samples?—Yes.

(*The witness explains the relation of the diagram to the table to the Commission.*)

9936. It would have been rather better, if I may suggest, if your five reaches had been marked in some different colours upon the wave diagram,—can you point out upon the diagram where they would come?

(*The witness did so.*)

(*Witness.*) The top line, that is to say the deep black line on the wave diagram, shows the organic carbon.

9937. Before you go to that will you explain what the Nos. on the left hand are, such as 0·1?—The Nos. on the left hand represent the quantities per 100,000 parts of organic carbon and nitrogen, and the figures at the lower part of the diagram cubic inches of free oxygen per gallon.

9938. You were explaining what the top line indicated?—The black line at the top represents the organic carbon. I wish to note that there are some points upon which there are dots upon these black lines, take for instance No. 12 on the wave diagram, that means that there is a small streamlet or river joining the Thames at that spot, and it is represented by a spot in a circle. It would be manifestly unfair to put the composition of the Thames so high as that, so I have put in a dot which represents the composition of the water which joins the main river.

9939. To put this in general language, you start at the extreme left of your diagram with Teddington?—Yes.

9940. The organic carbon seems to sink rather at No. 6; that would be opposite Richmond?—There are undoubtedly variations in the quantity of organic carbon, sometimes it is a little more, and sometimes it is a little less. I am not able to explain these discrepancies, but I think it fair in taking a reach to average all the results and see what we get.

9941. Then your first reach, that is to say from Teddington to Battersea, brings you down to No. 25?—Yes, No. 25.

9942. The carbon seems to be running up towards the end of that reach?—It is slightly, and upon the table I have put in showing the average analysis (Table II.) you have there the average quantities of organic carbon and organic nitrogen, the ratio of the

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

nitrogen to the carbon; in the first example it means 1 to 7·7, and the quantity of free oxygen is also given The quantity of organic carbon in the first section is ·216, and the quantity of organic nitrogen is ·028 per 100,000 parts

9943. Where is that?—In the reach from Teddington to Battersea. The ratio of the nitrogen to the carbon is 1 to 7·7, and the quantity of free oxygen is 1·48 cubic inches per gallon in that reach. I would say that it is perfectly true that in all these analyses you will be able to find different places where there is more at one spot and less at another, and we cannot give you any account or explanation of that; but in averaging a series of results you in a great measure minimise such things as experimental errors, and, I am sorry to say, that there are such things, and then you are able to get a very fair view by taking a number of samples in this way of the average composition of the water.

9944. You gave in this first reach from Teddington to Battersea, the ratio of the nitrogen to carbon as about 1 to 7·7?—Yes.

9945. In the water which came over Teddington it was about 1 to 8, was it not?—I do not think there is much difference, practically, you may take it as the same.

9946. With regard to the free oxygen, do you find that the same?—No; and that is a very important point; the free oxygen below Teddington is reduced very nearly by 25 per cent., there is a larger quantity of organic matter in the water, but the free oxygen in solution is sufficient to preserve its purity, that is to say, the organic matter is not increased, but the free oxygen is decreased.

9947. Am I putting it rightly when I say that your view is that from Teddington to Battersea the water remains pretty well as pure as at Teddington, but it is at the expense of the oxygen?—Yes, the power of self-purification is lessened, and that is the main point to notice up to Battersea.

9948. It uses up the oxygen and the oxygen is about sufficient to keep it as pure as at Teddington?—Yes; there is of course a contest going on between the organic matter and the oxygen, the oxygen being sufficient to keep the organic matter down.

9949. There are tributaries coming in such as the Crane and the Brent, have you considered their relation to the Thames?—Yes, I have. It is quite clear that, although they are certainly for the most part more impure than the main river, they do not materially affect the main river, the quantity or the rapidity of oxidation is such that practically the river is kept pure. I might say that I have taken no other estimation of the organic matters present except the organic carbon and the organic nitrogen, for reasons which I gave yesterday.

9950. With regard to ammonia, do you find much of that?—The ammonia is very little altered.

9951. And the matter in suspension?—There is an increase undoubtedly of the matter in suspension, but I do not think there is very much to say about that. I should like to say that the matters in suspension in reach No. 25 average eight tenths of a grain per gallon.

9952. Now your second reach is from Vauxhall Bridge to Deptford?—The second reach is from Vauxhall Bridge to Deptford, Nos. 26 to 35.

9953. By "reaches" you are not speaking of the reaches of the river?—No, they are simply arbitrary divisions of one's own.

9954. What do you find in that reach?—There is in this reach a manifest increase of organic matter, the organic carbon has gone up from 216 to ·323, the organic nitrogen has doubled, it has gone up from ·028 to ·054, the ratio of the nitrogen to the carbon is as 1 to 6, and the free oxygen again is reduced to 1·3 cubic inches per gallon, that is to say, concurrently with the increase of the organic nitrogen and with the alteration in the ratio we have a diminution of free oxygen; it is not a great diminution, it is true, but it is manifest. It appears to me that in this reach we have a portion of the river where the call that is made on the oxygen is almost the very maximum that the oxygen can bear. As a result of that the maintenance of purity in this reach is manifestly a difficulty, and I have no doubt at times it is impossible, but at the same time it is always manifestly a difficulty. I would say that I attach a great deal of importance to maintaining full æration for water, because I am quite convinced that in effecting the purification of the river the half-inch of free oxygen in solution between 1·5 and 2 cubic inches is infinitely more powerful than the half-inch between 1 and 1·5, that is to say the dilution, as in a good many other things, will render the activity far less than the mere diminution of quantity; in other words, say, that if a river has two cubic inches of free oxygen per gallon, and a purifying power of four, a river which contains 1½ inches per gallon has nothing approaching a purifying power of three.

9955. Now take the third reach from your No. 36 to 42, that is to say from Deptford to the Albert Dock?—Here the water becomes manifestly less pure, the organic carbon is doubled and the organic nitrogen quadrupled as compared with the previous reach, the ratio of the nitrogen to the carbon is as 1 to 3.

9956. And the free oxygen is reduced to 0·7 of a cubic inch per gallon?—I think that indicates that owing to a continuous stream of impurity the normal purifying action of the river water is interfered with, and its power of reparation seriously lessened.

9957. The next reach is the Beckton to Crossness Reach, from No. 43 to 53?—There, of course as you would expect, where the sewage was being discharged we get a very large increase of organic impurity in the water, a material rise in quantity. Thus the organic carbon is ⅛th greater in amount than in the previous reach, and 340 per cent. greater than at Teddington, the organic nitrogen is about 1,000 per cent. in advance of the samples in the first reach. The ratio of the nitrogen to the carbon is 1 to 2·5, while the quantity of free oxygen is not very different to that in the previous reach, it is a little less, but nothing to mention it is about $\frac{7}{10}$ths of a cubic inch per gallon. The importance of that fact is, I think, this, that admitting all one has said about oxidation, which I admit to the full, this is not a case in which sewage is poured into a water that possesses a power of self-purification, but where, by a constant pouring in of sewage the self-purifying power of the water is practically reduced to a minimum:—in other words you have taken away from it its power of reparation.

9958. You find that the oxygen is the same as in the reach above, as if no urther purifying by oxidation had gone on?—It is almost reduced to a minimum. The fact is the water had been trying to keep itself pure, it had a struggle in the reach between Vauxhall and Deptford, and after it had passed that reach it could not do any more, its power was exhausted.

9959. This reach from Beckton to Crossness is the one which receives the two outfalls?—Yes.

9960. Your judgment, I think, is that we must not treat this sewage as poured into pure water?—Certainly not, it is not the admixture of sewage and pure water that is ærated, it is the addition of sewage to sewage, and therefore it comes under a totally different category from any question relating to oxidation. Then there is another thing that relates to that point. Of course I know very well you will hear much about the purifying action, and that what I wish to draw attention to is the fact that this is the addition of water to a water containing a very large quantity of common salt, and we know the preservative action of common salt. We have therefore two very remarkable conditions, firstly, an enormous quantity of common salt, itself an antiseptic, and, secondly, a water in which there is practically no oxygen which is capable of acting at all.

9961. The sewage therefore remains to a large extent in its original condition, it is not burnt up by the oxygen?—I would not say that none of it is, but practically that result is reduced to a minimum.

9962. (*Professor Williamson.*) I understand you to say you believe the activity of the oxygen in destroying the organic matter is not in direct proportion to the amount of it, so that if there are 2 cubic inches per gallon you believe they act more than twice as strongly as one would act?—Yes; but I did not give those numbers.

9963. Have you made experiments in relation to the truth of that observation?—I cannot fix the exact relationship, but I can say that the power of self-purification which water possesses when it contains from 1·5 to 2 is infinitely greater than it possesses when the quantity of oxygen it contains is from 1 to 1·5.

9964. You are certain that the operation of it is much stronger?—Yes.

9965. Have you facts to furnish in support of those observations?—I have not with me, but I have carefully studied the matter. I made the remark that four was more than equal to double two, but I was not quite prepared to say what it was equal to.

9966. (*Chairman.*) This is the result of your own experiments and observations?—I have made a great number of experiments from time to time upon the oxidation of water, but I would say that when you get to a quantity like half a cubic inch the purifying power is almost reduced to a minimum. (*To Professor Williamson.*) I am sorry to say the facts you wish for, of which I have some memoranda, are not tabulated, but I will have, or endeavour to have, it done.

9967. (*Mr. Lumley Smith.*) Now I find the River Ravensbourne coming in at the beginning of your third reach, does that bring in much water?—No.

9968. Is that a disturbing element?—No; as a matter of fact I think I may say the Ravensbourne is purer than the main river.

9969. Now you have gone below Crossness?—Yes, I have gone to Erith and Purfleet; and I can only put the facts before you as to that reach. The organic carbon is ·718; the organic nitrogen ·176; the ratio of nitrogen to carbon 4·0 and the quantity of free oxygen ·508 cubic inches per gallon. What is the exact meaning of that alteration of the ratio of the nitrogen to the carbon I am sorry to say I cannot at the moment explain. I can only speak of the fact, I am sorry for the variation, because in all one's other observations there has been a certain amount of uniformity.

9970. (*Professor Williamson.*) Have you determined the ammonia?—Yes.

9971. What becomes of the nitrogen which is separated from the ammonia in the lower reaches, is it present in the form of nitrates or ammonia, or have you traced it?—I cannot say that I have, but I would say that if you refer to the ammonia column in the large table you will find the ammonia throughout given; but then there is another thing to be said about that ammonia which is this. I have not made a great deal of it for this reason, and that reminds me of another thing, that when you bring a sample home there is no doubt that the estimation of ammonia is not a very accurate thing, more especially for instance if you keep it a certain time. And there is another thing I would venture to say with respect to the estimation of free oxygen, there is no doubt that the estimation of free oxygen would be very much better made on the river itself; but as a matter of fact I have found that by taking a bottle quite full and putting the stopper in close upon the water so as to avoid any shaking about of the water, if the estimation is made within a short time (and I always make a point of having it made the following morning when the bottle is opened) I find it comes right within the second place of decimals.

9972. (*Professor Williamson.*) How do you manage to have your bottles filled with water, is the air in them displaced by the water?—The air is displaced by the water, at any rate they are all taken under the same conditions, it would be difficult to follow any other course.

9973. Unless you had a circulation of water through the bottle?—You might have that, but the bottle is practically lowered a foot below the surface and filled, and then the stopper is put in when the bottle is absolutely full.

9974. So that it displaces some of the liquid?—Yes; I find that if the estimation is taken within a short time it is very little altered, but if you have a quantity of air in the bottle and you allow it to tumble about, you do get an alteration.

9975. (*Dr. Stevenson.*) You mentioned the Ravensbourne, now I observe a considerable jump in your diagram at that point, can you attribute that to any cause beyond the Ravensbourne?—I cannot, because if you look at the quantity of organic matter in the Ravensbourne it is less than in the main river; but I should like to say that I did not take the sample of the river Ravensbourne, that is one of the two which I did not take.

9976. (*Mr. Lumley Smith.*) With regard to those little round circles which are put in as representing the contributory streamlets, are they put at such a height as to represent the amount of carbon or nitrogen of that river?—Yes, they are.

9977. Then taking your river Brent, which is on No. 12, the amount of carbon in that is greater than the amount in the Thames?—Yes, it is.

9978. It makes a considerable jump, but I see it does not cause very much difference in your wave?—No, but it is a curious thing, and it is worth noting, that the spot where the rivers Crane and Brent come in, although there is no increase in the quantity of organic matter, there is a very considerable decrease in the quantity of free oxygen; that is to say, there is no doubt that the free oxygen has been maintaining the purity at that spot.

9979. Nearly all these rivers seem to me to be worse than the Thames?—Yes manifestly. There is a mistake I should like to point out, and that is the free oxygen of the river Wandle, which is put down in the table as ·01, whereas it ought to be ·1.

9980. That would bring it to about the same amount of oxygen as the river itself?—Yes it does.

9981. Is it right as regards the nitrogen and carbon?—Yes.

9982. Now, have you exhausted what you think would be useful information upon these tables?—Yes; but I should like to mention that I believe evidence has been given about some samples which have been taken at All Hallows pier. I will put in the analyses (*Table* 13, *Appendix AG.*), but I have nothing further to say myself about them.

9983. With regard to the river Ravensbourne, do you know whether any storm overflows were at work in the neighbourhood?—I do not know in the least; the samples were brought to me by a man of the name of Lewis.

9984. Now, with regard to the samples that were taken at All Hallows pier, what you are handing in are the results of samples of Thames water collected at All Hallows pier?—Yes.

9985. Which reach is that in?—It would be in the reach between Battersea and Deptford.

9986. What are you going to tell us about these?—I have not anything to say about them except that they are confirmatory of the other observations.

9987. What is your next?—The samples taken at the Northern Outfall at Barking; those were not taken by myself. I believe that there has been evidence given of the taking of those samples.

9988. Will you just state what this table (*No.* 5, *Appendix AG.*) shows?—I am bound to say this, that I think it shows very little. The fact is, these were samples taken at the Northern Outfall, Barking, but it is perfectly clear they are not pure sewage; here are samples with 187 grains of chlorine in them; it is quite clear a great deal of it is Thames water. There is one, No. 19, which contains 11, and there is one, No. 20, which

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

contains 10, and in those cases the organic carbon is 4·8 and 3·9 respectively, but, as regards a great many of the other samples they are not sewage at all.

9989. They are a mixture of Thames water, sewage, and sea water?—They are simply mixtures of sea water with river water and sewage. I would say that some of these samples had a very strong sewage odour when they were furnished, whilst others after being kept a short time became very offensive. The quantity of free oxygen in these samples is worth noticing, and I am rather disposed to think if you had perfectly pure sewage you would find hardly any free oxygen at all, or only a very small quantity. It is manifest that these samples were mixed with sea water, and therefore, except that they have been referred to in the course of this inquiry, I should not have put them in. Now there are some samples which have been spoken of as having been taken at Crossness. (*Table No.* 6 *was handed in.*) These have been mentioned as having been sent to me, therefore I put in the analyses of them, but I venture to remark that the outfall of the sewage at Crossness is below the level of the river, and therefore all they could do in taking these samples was to lower the bottles into the river. That was the only method of taking the samples at all, and it is perfectly evident that what they got was a mixture of sewage and some sea water. The quantity of chlorine contained in the samples shows that it was hardly worth while taking them at all.

9990. The sewage you mentioned as containing 10 parts in 100,000?—Yes.

9991. Then that chlorine column shows that there is a large admixture of sea water?—Yes.

9992. And that title "sewage water" in your judgment is not correct?—If you mean by sewage water, water which contains some sewage, I accept it; it does not mean that it is true sewage; it means rather sewage and water, I presume.

9993. Have you any observations to make upon at table?—I think not, except that there are large quantities of ammonia in some of the samples. Now I will put in an analysis of a series of samples at Beckton. (*Handing in Table No.* 7.) The Beckton Gasworks have been referred to in this inquiry several times, and having occasion to go to Beckton periodically, I have made a point of taking a sample of the actual sewage itself upon the dates mentioned here in order to see to what extent this small thimbleful of materials which comes in at Beckton does pollute the river.

9994. It has been suggested that the sewage at Beckton does pollute the river?—Yes.

9995. (*Chairman.*) Where did you take the samples?—From the "catch" before it gets into the river; but here again it is manifest a considerable quantity of sea water has got into as it got into the Barking samples; and it is also noticeable that the amount of organic carbon and organic nitrogen is comparatively small. Though I do not dispute for a moment, I do not think there is a doubt about it, that the outfall does contain some sewage, because I know it does, nevertheless, the quantity of sewage is comparatively small. But there is another peculiarity to be noticed about these samples, and that is the quantity of ammonia present in them; that is very large. But we must remember that this is a gas-works, and although it is to the interest of the gas-works to preserve every particle of ammonia that they possibly can, and although as a matter of fact the plant at Beckton is admirably arranged for the purpose still there must be a little less, and that would account for the relatively large quantity contained in these samples. I know that at Beckton, and I am speaking now from what is within my knowledge, and within my own knowledge more than perhaps within the knowledge of most, exceedingly perfect arrangements exist for the purpose of retaining every drop of ammoniacal liquor, and they would not allow it to run to waste, still a slight leakage is incidental to all gas-works.

9996. They sell the residual liquor, do they not?—They convert it into the salts themselves; they do not sell it.

9997. Do you know what their process is of dealing with the sewage, is there anything to intercept the sewage?—No, it is only from a few houses. I think there are gaugings taken by Mr. Latham of the actual quantity.

9998. In the samples taken at Beckton do you find chlorine?—Yes.

9999. Does that indicate salt water?—Yes, there is some backward flow.

10,000. Here, as in the Crossness and Barking samples, does the suspended matter column show anything that is material?—At Crossness there is a considerable quantity. I think this is worth noticing, if I may be allowed to mention it, that in sample 17, for instance, at Barking, and again in sample 19, which looked to me more like samples of pure sewage than the rest on the ground that they contained very much less chlorine, the quantity of suspended matter is 35·4 and 31·1 respectively; I think that it is noticeable, that is to say, that in the samples in which I have no doubt we have got a purer sewage than in any other, the quantity of suspended matter is over 30 grains a gallon. That is also the case in No. 20, where, no doubt, from the quantity of chlorine it is more like true sewage, that there you have 29·2 grains of suspended matter per gallon. I do not wish to make more of it than is the fact, but I have no doubt it is so. Would you allow me at this point before you begin another part of the inquiry to put in some analyses about which I have nothing to say, but which will be dealt with in greater detail with some other analyses by Dr. Frankland afterwards, but it is necessary for me to prove them; I will only just put them in and nothing more.

10,001. (*Professor Williamson.*) There is one point you touched upon a little while ago upon which it would be interesting if you would give us some further information if you happen to possess it. I allude to the remark you made when you spoke of the diminution of the oxygen as you proceeded downwards in the river, and the consequent diminution of the influence which tended to destroy sewage. I understood you to say that in proportion as the oxygen diminishes in the manner you described, the quantity of salt which comes up in the sea water increases at the same time; and if I understood you rightly, the salt exercises, in your opinion, an action opposite to that which the oxygen exercises, that the salt which is present exercises rather a preserving power (I think the word "antiseptic" was used), which tends to preserve the organic matter as such, and to retard if not to diminish its decomposition. Now is that the result of definite well known facts, or is it the opinion you have formed from general probabilities, because of course you are aware the sea water brings not only salts but sulphates, and if those sulphates undergo decomposition under conditions which are not uncommon, surphuretted hydrogen is evolved?—It would be evolved by the decomposition no doubt, but with respect to the question of the salt I am afraid I have no facts to give you, my remark was of this kind, or at least I wished it to be, that in pouring sewage into running water (a question upon which I have often given evidence before) I had not the element of 300 or 400 grains of common salt to contend with, and knowing that it possesses a certain preservative power I was not able to say what was the preservative power it might exercise upon the organic matter. I have no experience to give you upon that question. Upon the question of the activity of certain proportions of oxygen, I think I am able to give you some facts. Would you allow me to say that the question of the reduction of the sulphates and the action of carbonic acid on the sulphide will be a matter upon which I shall speak afterwards. I have not lost sight of that action. As regards the chlorine I do not wish to suggest that I have any facts except *a priori* reasoning.

10,002. (*Mr. Lumley Smith.*) Are you now coming

to the result of your microscopic observations, or have you anything to suggest before you come to that?—I would prefer to go to that branch of the subject now.

10,003. You were going to say something I think before we passed on with regard to the sixth report of the Rivers Pollution Commission?—I will give you the reference to it. The composition of sea water was given by the Rivers Pollution Commission in their sixth report, and they closely confirm the analysis, in fact absolutely confirm the analysis which I have put in, on page 132 of the sixth report. If you will allow me I will read it. "In every case the organic matter "was highly nitrogenous, the proportion of nitrogen to "carbon varying from a ratio of 1 to 7·8 where we get "more nitrogen than carbon to 1·483, averaging a "ratio of nitrogen to carbon of 1 to 1·83." We have therefore an enormous concentration of the nitrogen on the carbon in some way or another, whether that is due to the fact that carbon is a body which is more easily oxidised than the nitrogen, so that we lose the carbon where we do not lose the nitrogen, or whatever it may be due to, there is the fact.

10,004. We are passing on now to the results of the microscopic observations, and perhaps, as a matter of personal convenience to me, the Commission will allow my learned friend Mr. Balfour Browne to examine you as to those results.

(*Chairman.*) Certainly.

Examined by Mr. Balfour Browne.

10,005. Have you examined the deposits in the various waters of the River Thames microscopically?—I have examined an enormous number of them, some thousands.

10,006. In doing so did you employ a staining fluid or did you look at the samples as they were?—As a matter of fact I adopted both ways.

10,007. (*Chairman.*) What system did you adopt?—What I did was this, in the case of a mud or of a deposit, I got it first of all into a conical glass vessel; if I could get a mud I took a considerable quantity of it, if I took a water I collected the whole of the deposit from a considerable quantity of water, mixed it up with distilled water and then allowed it to deposit.

10,008. (*Professor Villiamson.*) You did not filter it?—No; the object of that was that the heavier particles of mineral matter should go down first, and that I should in that way get upon the surface of the deposit, a layer of the lighter and flocculent organic matter. In all those cases if possible I took a duplicate sample to which I added a solution of hæmatoxylin for the purpose of staining. The real object of this was that I might bring out more distinctly any animal tissues that were there; and all the deposits and all the muds taken have been examined in that way. But before doing that, I set to work perhaps somewhat laboriously, to take the microscopic appearances of fæcal matter and the appearance presented by a water, to which I added a certain quantity of fæcal matter, mixed with other mineral matters, and in doing so I took advantage of an exceedingly elaborate investigation which has been recently made, and which I have perhaps taken as the basis of my work, by Professor Nothnagel.

10,009. Have those researches been published?—Yes.

10,010. And what was the substance of Professor Nothnagel's researches?—The substances that he pointed out as being of almost if not constant occurrence in fæcal matter, were first of all four things; muscular tissue, yellow elastic tissue fibres, shreds of fibrous substances such as fasciæ, and lastly, about which I shall have a good deal to say, spiral and free vegetable cells.

10,011. With regard to your investigations into the mud and river deposits, were they undertaken with the view of tracing these substances if possible?—Yes, those were the points to which I gave my attention in the first instance, but before proceeding to state the microscopic appearances, I venture to notice two things about these muds and deposits, the first is the absence, in the majority of cases, of any smell; that is to say, when the sewage mud is taken up from the bed of the river, it very often has no smell, but it will be invariably found that when it is kept in a warm place, as for example in a warm laboratory, the smell readily becomes very offensive. I presume the explanation of that is, that some of the more easily putrescible matters have undergone decomposition; then there is an interval, and then other matters become putrescible. It is quite clear that in observing the action of a quantity of sewage thrown into a very large tub, for instance, which I have done on a good many occasions, noting it day by day, there is a time when it smells very offensively; it then goes down and does not smell at all, then if you take a stick and rake it up you get the smell again, in fact you almost carry out what is done upon the river by the action of boats stirring the deposit up.

10,012. (*Mr. Balfour Browne.*) Have you ever taken up sewage mud from the bottom of the Thames when the temperature was very high?—I am certain to have done so, but I have no particular recollection of any one occasion.

10,013. Can you say whether that is or is not the odour you have detected in the laboratory?—I have smelt muds from the Thames which smell very badly, but some of them do not smell.

10,014. At any rate they develop a choicer bouquet when they have been kept in the laboratory?—Yes. Then another characteristic of a sewage deposit is a floculent and ill-defined surface; that is to say, if you take a large hand magnifying glass and look at this deposit in the conical glass, you will find that it has an ill-defined surface, it is a flocculent surface, whereas in a non-sewage deposit you will find you get a perfectly smooth well-defined surface, and the supernatant liquid is fairly clear into the bargain. What is very characteristic of the sewage deposit is the ill-defined surface and the absence of brightness of the supernatant water.

10,015. For this purpose you have compared sewage mud with non-sewage mud, have you not?—A very great number of times.

10,016. The inequality of surface is one thing that you have mentioned, but is it also the fact that the glass is dimmer in the one case than in the other?—Yes, taking a large conical glass, the dimness of the sides of the glass in the case of the sewage is a very marked feature of the observation.

10,017. The first series of observations were conducted with what I think you call undoubted sewage muds and deposits?—With undoubted sewage muds and deposits. I started with that in a great many cases, taking absolute sewage, also taking sewages that were artificially manufactured, and so on. I believe I did it in every way I possibly could.

10,018. Could you give us the dates over which those experiments ranged?—I may say these experiments were commenced for the last investigation in 1879; and since then I have been continuing them from time to time, and lately, since this case has come forward, I have done a great many more.

10,019. They are practically carried down to the present time?—They have been going on for three or four years. Now the first series of investigations were conducted for the detection of muscular and yellow elastic tissue, fibrous structures, vegetable cells, and other tissues. I took these because Professor Nothnagel had referred to them in his paper. Now as regards muscular tissue, fragments of muscle with distinct striation are constantly found in fæcal matter, but in sewage mud and deposits they are very rarely found indeed, and I think that depends upon the fact that striated muscle rapidly undergoes decomposition, and that amongst the earliest signs of that decomposition is loss of striation, and that where loss of striation occurs it is

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

practically impossible to identify muscle in the mixed solution.

10,020. Does that decomposition of striated muscle take place more rapidly in water?—Yes, it does. In order to illustrate what I have done in this matter, I have had some chromo-lithographs taken to make it clear to the Commission, they only represent a few of the enormous number of drawings I have done to illustrate this case. I will first of all put in one plate and then another (*handing in some coloured representations*).

10,021. You have spoken of muscular tissue, is there anything upon these plates which shows what you have spoken of as striated muscle?—Yes, I have drawn one sample, it is only an ordinary piece of striated muscle which I found myself in a sample of water that was sent to me from Beckton, that appears in Plate A, Figure 2, and the small (a) in Figure 2. Now the next thing is yellow elastic tissue, that is shown on Figure 2 at D; and I would say that that again is a bit that I found in the sewage matter outside Beckton.

10,022. Before you go further, is that yellow elastic tissue a very important matter as characteristic of sewage?—It is exceedingly important and exceedingly characteristic. It is important because, unlike muscular tissue, these fibres resist putrefaction to a most extraordinary extent, they also resist the action of very strong chemical solvents into the bargain for a very long period; therefore the existence of that yellow elastic tissue is a very important thing. They not only resist putrefaction and the action of strong chemical solvents, but they are rendered unusually distinct by the decomposition of the tissue in which they take part, so that really when they are to be found, they become clearer from having passed through the alimentary canal, and clearer from the action of the water.

10,023. (*Chairman.*) How would you describe the small (d)?—As the yellow elastic tissue.

10,024. Will you state to what power they are magnified?—It is practically Ross' fifth that they were examined by, it is higher than a quarter of an inch. I think you might say they are magnified to 250 diameters. That being a very important thing, I would say these fibres are very frequently met with in muds, and very frequently met with in the deposits in question, near the outfalls, that I shall have more to say about.

10,025. (*Mr. Balfour Browne.*) You told us that the yellow elastic tissue resists the action of decomposition better than the striated muscle?—Yes.

10,026. Is it therefore much more commonly found in the muds than the straited muscle?—Yes; indeed I have given up practically the search for muscle now, because I know how readily it disappears and how accidental it is.

10,027. The next thing you looked for was the shreds of fibrous substances?—Yes, they are very often met with, particles for instance which probably make up the tendinous and fascial tissues are very often met with near the outfalls, and like the yellow elastic tissue, these particles also resist for a very long time decomposition.

10,028. Are you taking them in the order in which they resist decomposition?—No, I cannot say that I am, I am taking them as they come.

10,029. You have found these substances under the microscope?—Yes.

10,030. Have you figured them upon your diagram?—Yes, I have, but I will hand that in directly.

10,031. (*Chairman.*) The fourth division was the spiral and other vegetable cells and appendages?—Yes, as this is a matter of such very great importance I will try and make clear what I have to say about it. Of course the appearance of vegetable matter and particles of vegetable cuticle can be of no importance in determining the fæculent nature of any deposit, that is to say, vegetable matter will get in any way, and therefore that can be of no importance; but there is a very great peculiarity in the vegetable matter which has passed through the alimentary canal, that is the setting free of solitary vegetable cells or the setting free, more especially, of spiral vessels. On Plate 3 you will see the free spiral vessel has no investing membrance round it.

10,032. (*Professor Williamson.*) Were those samples obtained all in one field?—No, I am not giving them as actual samples, I am giving them to illustrate my evidence, they have been all put together in this case. Now the important part about these cells, and I am quite clear upon this point, therefore I speak definitely, the peculiarity I say is, that when the vegetable tissue passes through the alimentary canal the investing membrane will be dissolved, but the free spiral vessel is not acted upon by the fluids of the alimentary tract, that is to say, you may get the material containing this spiral (and I think the spiral is the most important infinitely) passed through the alimentary tract, everything dissolved off and the free spiral left alone. Now I have made a very large number of examinations of vegetable matter submitted to decomposition to see whether I could get a free spiral by simply decomposing vegetable matter, and I say I have never upon any occasion (and I have examined leaves of all ages and particles of cabbage which I have exposed to every form of action) seen the free spiral vessel produced as the result of ordinary decomposition.

10,033. Beyond the ordinary, the alimentary?—No, as the result of ordinary decay I ought to say, because there are two ways by which I could imitate these spirals; the first is by the action of boiling. If I take a quantity of vegetable which contains a large quantity of free spirals, like cabbage, I can by boiling separate the membrane and get the spiral; and the second is by the action of an artificial digestive fluid; that is to say, if I take a solution of pepsine and slightly acid pancreatine, I get a digestive fluid, by which I can separate the spiral, but I do not otherwise get perfect free spirals, so that free spirals are only practically produced by passing through the alimentary canal, and therefore the free spirals become exceedingly important as proving the existence of sewage. Now when vegetable tissue decomposes it generally decomposes *en masse*, the whole thing disappears. As regards that spiral vessel it seems to be, and certainly it is, very difficult to decompose it at all; when it is in the river it really remains a very long time unchanged. It is very different in that respect from muscular tissue, and whatever be its composition, about which I am unable to speak, all I can say is that it seems to be exceedingly persistent.

10,034. Is that in Figure 3 an unwound spiral?—It is an unwound spiral.

10,035. (*Chairman.*) Did I understand you to say that when pure vegetable matter is exposed to natural putrifaction, the spiral goes readily like the rest of the vegetable?—At any rate you cannot see it; I suppose it all decomposes *en masse*.

10,036. But when it is separated from the external membrane, either by passing through the alimentary canal or from the application of the ingredients you have mentioned, then the spiral membrane is not decomposed?—I do not say it is not decomposed, but it resists a considerable time, I do not say it resists longer under those conditions than in the other case.

10,037. That is what I wanted to know?—That I am unable to say, because the decomposition of leaves and other things is a matter of considerable time, and the whole might go together; I am unable to say that, but I only say that when you get these vessels let free they do last a considerable time, of course the decomposition of vegetable matter itself is a comparatively slow process.

10,038. (*Professor Williamson.*) If you could examine them step by step, perhaps you would find some of the tissues would last longer than others?—One would suppose so, but I have always found that the spiral tissue lasted very much longer than the others. I have examined leaves which have been decomposing two years old, but I have never yet seen a spiral left. I should like to say before I leave the spiral cells that

there is nothing in them that could be mistaken, they are as definite as possible, and they are as magnificently clear as anything you ever saw, there is no mere hazy outline to them.

10,039. (*Mr. Balfour Browne.*) There are also hairs of wheat and other cereals found in the sewage mud, are there not?—Yes, those cuticular hairs are very persistent, I had an idea at one time that they were broken bits of diatoms, but I have come to the conclusion that they are different things now.

10,040. Do you also find starch cells?—You occasionally find starch cells also.

10,041. I think some of them are shown upon your diagram?—I think not.

10,042. The hairs of wheat are shown upon your diagram?—Yes, they are, but I am afraid they do not represent the hairs very well there.

10,043. What is the next feature you have to mention which is characteristic of a sewage deposit?—You may look at many examples of deposit and not find the hairs or the spirals; but one of the most characteristic features of the sewage deposit is the yellow amorphous matter.

10,044. (*Chairman.*) When you speak of sewage deposit you mean fæcal deposit?—Yes, I am referring exclusively to the animal contamination.

10,045. (*Mr. Balfour Browne.*) You call that yellowish?—Yes, I call that yellowish, and it is distinctly yellow under the microscope. I think in this diagram it is a little dark, but at the same time it represents it fairly well. That deposit is important, because it undoubtedly is the most conspicuous feature of the sewage muds and deposits, and I have no doubt in my own mind, not a shadow of a doubt, that the origin of that material is animal.

10,046. In ordinary river muds there is a considerable amount of matter, what does that look like under the microscope, is it all like this, or is it angular?—It is totally different; I have shown at Figure X in the diagram the appearance of a mud-water deposit, which is not sewage, and it is perfectly definite, it has a number of sharp particles, you will find that there would be a sort of even layer of particles, of course it will vary a good deal, there would be a few pieces of vegetable structure, and you may get some diatoms and such like, but there is one thing which is very important to my mind, and that is its non-clustering appearance, you will find the whole field of the microscope is fairly and evenly covered, and when you look further you will see these particles (depending upon how successful you have been) evenly covering the entire field.

10,047. You say the particles have an angular shape?—Yes, the particles have an angular shape and are highly refracting.

10,048. Is that appearance at all seen in what you call the yellow amorphous matter?—It is totally different.

10,049. Have you seen anything like this yellow amorphous matter in any other matter?—Yes; I have examined it a great deal, it resembles portions of disintegrated muscle and matter from the dissecting room which have been in the water a long time. There is no doubt that by disintegration you get matter of this kind.

10,050. And have you ever tried the disintegration of such matters under water?—Yes, I have.

10,051. Is this appearance produced by decomposition in water more than in the air?—Yes; that deposit exactly resembles the molecular matter which is certain to result from the utter disintegration of animal tissues kept under water, and it at once distinguishes it from the disintegration of vegetable tissue. I think when one has seen it a good many times it would not be possible to mistake the disintegration of vegetable tissue for the disintegration of animal tissue under water.

10,052. What is the particular feature of vegetable decomposition?—A coarse sort of breaking up. It is a very difficult thing to express what takes place, it is in large pieces, and nothing like the simple amorphous granular material, distinguished by the breaking up of animal matter. I have, upon the whole, no doubt that the yellow amorphous matter is of animal origin.

10,053. (*Dr. Stevenson.*) Have you thought whether it might be attributable to any altered blood pigment?—I have wondered whether the yellowish material may be due to bile in any way.

10,054. (*Mr. Balfour Browne.*) Besides the granular yellow matter you describe are there other masses which appear?—May I first say that one has thought of all the various points that might be raised as to the yellow amorphous matter being indicative of animal rather than vegetable deposits; one might be tempted to say, for instance, in the case of vegetable cells, might they not break up and form a granular mass of this nature; I do not think they could. I can quite understand such a question as that being raised, but I entirely doubt whether in the breaking up of those cells we should get a body of that kind, still I can quite imagine the question being raised.

10,055. (*Professor Williamson.*) In the question you have raised under the head of disintegration, you assume that some putrefaction is occurring, you do not merely record a falling apart of solid constituents which were together?—No, I do not think that, so much as an actual change of the particle; for instance, keeping particles of muscle which I knew to be muscle, in water, I do not think you notice disintegration of the muscle so much as the loss of the striation of the muscle, there is disintegration really, but still it is a very minor form of disintegration. But when you lose that striation entirely, then it is impossible to say it is muscle.

10,056. Do not you find living organisms present while decomposition is going on?—Yes, undoubtedly, but I am sorry to say I cannot make very much of them.

10,057. You have not been able to examine them?—I have examined them, and I have examined into the diatom; in nearly all cases of sewage mud you will find shells of diatoms, and in some of them you will find the diatoms in active motion; but they are certainly not so frequent in mud which is not sewage. However I have never been able to know how far I could connect diatoms with the sewage, and it is very difficult to say, (equally so I think) with respect to the animal life which is generated under those circumstances, I am afraid I have nothing to say upon that subject.

10,058. (*Mr. Balfour Browne.*) To follow up the question which was put to you by one of the honourable members of the Commission, you say you do find organisms the result of putrefactive changes?—Yes.

10,059. You cannot trace organisms when the putrefactive change takes place in the muscle of a different kind from those of vegetable putrefaction?—No, I cannot find that. In an infusion of hay, you get them developed, and in an infusion of decaying animal matter you get them developed, and I cannot tell the difference between them. It is very difficult to deal with the question of living organisms. But may I add with regard to the young vegetable cells, my own impression is that the cell loses its characteristic aspect the moment its cell wall breaks, and I do not think a breaking of the cell would produce this effect even in young vegetable cells.

10,060. The breaking of young vegetable cells will not account for this yellow amorphous matter?—No, it will not.

10,061. Now upon plate A, what have you to say?—Here I come to another thing, which is to my mind very important, and that is the appearance of certain yellow masses; the yellow masses are, I think, distinctly different from the yellow amorphous material, (*pointing to the plate*), they are nearly or always found in sewage deposit, and I think that they are undoubtedly animal.

10,062. Upon what ground do you think that they are undoubtedly animal?—First of all there is an entire absence of every kind of vegetable characteristic about

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

them. Then secondly, they present the precise aspect of disintegrated animal tissue. I have seen them over and over again from particles I have examined which I knew to be animal; you will very often find in those minute lines, dotted lines, and I think it would be very hard to conceive that those dotted lines could come from vegetable matter.

10,063. Are the dotted lines the same thing as we saw in the striation?—No, I do not think that. Then thirdly, I think this more important than all; I have seen several pieces where you will find a piece of muscular tissue at one end converted into a yellow mass at the other. I have drawn one specimen of that; it was a very remarkable one. You will notice (*pointing to the diagram*), that actually at one end you have the muscular tissue and at the other end you have the yellow mass. I do not know whether that has been due to some particles being placed over that particle so as to prevent its decomposition at one point.

10,064. Where is that?—That is 2*c* at the bottom of the plate. As a matter of fact the specimen which I have drawn there, I found in the mud of the Thames off the sewer outfall at Barking, and there you get the actual transition from muscle to this peculiar condition. I once said it was an adipoceratous condition, but I can only say if you take the covering glass and press it, it is distinctly soft, you can press it out. I think distinctly it is an adipoceratous condition.

10,065. (*Mr. Bidder.*) I think I recollect that particular piece; he is an old friend of mine?—I have brought that forward before,

10,066. (*Mr. Balfour Browne.*) Now is there anything else besides what you have mentioned which shows that this is of undoubted animal origin?—Yes, I have found many pieces since in which I have no doubt the fasciæ and tendons have been converted into this yellow mass; so that not only do I think these yellow masses may arise from the change which the muscle would undergo, but at the same time tendon and fasciæ would undergo the same change. I will now, if the Commission will allow me, hand in another plate, plate B. (*handing in the same*). I will refer you to Figure 3.

10,067. In that figure the portion of tendon is found in the water?—Yes; there for instance is a beautiful piece of tendon in a water deposit taken at All Hallow's Pier. Now there its fascial character is distinctly marked, and it has undergone conversion into this peculiar yellow deposit. I have seen a number of pieces, not only of muscle but of various forms of animal deposit which have undergone this change.

10,068. You have already mentioned the diatoms. are they found often in samples of sewage mud?—Yes, I thought at one time that one would have been able to make something of diatoms, but I do not think one can.

10,069. Would you or not say that diatoms are indicative of sewage mud?—I think that where you get sewage you invariably find perfect fusiform diatoms. I thought a great deal more once of diatoms than I do now. I think, in the previous inquiry I made more of diatoms than I do now, but I do not think much of them; still I think they may have something to do with the question.

10,070. You put in both these plates, but I wanted to draw your attention to any observations you may have to make with regard to the appearance presented by the sewage mud or deposit?—There have been a good many things I have thought of in regard to this question, that is to say, I have put two muds together at the bottom of plate A, a sewage mud and a non-sewage mud. Of course one thing which has occurred to me has been this. It might be said animal contamination is in the river, supposing that is admitted might it not come from the decomposition of large quantities of bodies of animals, dogs, cats, rats, and so on, thrown into the river.

10,071. X and Z are the figures you are directing attention to now?—Yes.

10,072. Are those actual specimens?—Yes, they are actual specimens, and each group was drawn exactly as I saw it; there is no collection here in these groups. Table B also gives actual specimens. Now the thing which struck me was that if these things were derived from the decomposition of the bodies of animals, first of all, in my opinion, the decomposition would more or less occur *en masse*; but secondly it appears to me that we should have found the hairs of animals more frequently in the river. In the numberless deposits I have examined from the river, I never found a hair but once, and that was the hair of a mouse.

10,073. (*Chairman.*) Do you find no human hairs in the mud?—No, and I am bound to say it is a very astonishing thing, I cannot tell you what is the meaning of it, I never found any hair at all except as I say, in one case the hair of a mouse.

10,074. (*Colonel Ewart.*) I have heard that at Bedford they complained that their pumps were choked by hairs?—So I understand.

10,075. (*Dr. Stevenson.*) Does hair readily decompose?—No, it is very indestructible.

(*Mr. Bidder.*) But that hardly explained it, because a good deal of the sewage does not come from the pumps.

10,076. (*Mr. Balfour Browne.*) If this animal matter were to be traced to dead bodies decaying in the river, like dogs and cats, and so on, you would have expected to find hairs?—Certainly.

10,077. Is it to your mind indicative of the fact that this decaying matter is coming from the sewage that no hairs are found?—That is an inference that one may fairly draw; and I think there is another thing, that the tolerable uniformity in which the animal fragments are found in certain samples of the mud deposit can suggest nothing but an extensive and a somewhat constant source of supply of animal matter. I do not know whether I convey the meaning I wish. I mean that the constancy of the appearance along the river seems to suggest to me a constant supply of the material.

10,078. (*Dr. Stevenson.*) Do you never find cotton and woollen fibre, house flannel fibres, and so on?—I have found cotton fibre, undoubtedly; a good many things I could mention I have seen that I have not put down here; for instance, I have no doubt whatever in my own mind that I have found blood cells. Starch again is a very common thing, but I have not burdened my evidence with those points; certainly cotton fibres I have found very of ten, but the absence of hair I admit is to me a very astonishing thing.

10,079. Have you found in these deposits fragments of dead worms?—Yes, lots of them; that is another thing that is somewhat remarkable.

10,080. Could they be mistaken for anything else?—No, they could not be mistaken for the animal tissues I have been referring to.

10,081. What kind of worms were they?—It was difficult to say, but it was perfectly evident from their look that they were worms.

10,082. Would you first refer to those two specimens and point out the characteristic of the sewage mud and as compared with other mud?—Taking these two specimens (*pointing to the diagram*) for instance, I have not put in the spiral upon the Fgure Z, because I did not see it when I drew it, therefore I left it out; out in Figure X there are particles of vegetable fibre, also are particles of a highly refracting body, silica, no doubt, and there is that dotted appearance of small mineral particles about the field; but an absence of clustering; there is no yellow amorphous matter, it is a sort of even layer; the extent of evenness depending to a great extent upon how far you have worked your specimen down. Then may I say with respect to the other sample, the Figure Z, you have there what is seen practically in every case, and that is the yellow masses and the yellow amorphous matter; it contains the hairs of wheat and some little bits of

dirt; and there is this curiosity about the yellow amorphous material which is shown upon that drawing, that in some cases you get a shapeless outline, whilst in other cases you get definiteness of outline.

10,083. In one case the matter, whatever it is, is evenly distributed over the field and in the other cases it is clustered as in Figure Z?—Yes, I have not a single doubt about the appearance of the sewage, and of the non-sewage deposit. The fact is that you get these particles of sand under the microscope, and you see little bits of this yellow amorphous material clustering round them, and it becomes very distinctive.

10,084. Can you trace the distinct characteristics of sewage mud more in the specimens taken near the outfall, and do those diminish as you get away from the outfall?—Yes, those deposits in the river, for instance, change their character; they change their character principally, I think, from two causes; first as the sewage deposit goes down the river, the solid constituents by reason of their different specific gravities undergo a process of sorting, that is to say the lighter particles will be found at a very much farther distance from the outfalls than the heavier particles; for instance, you will find that the deposits in the muds in different parts of the Thames are exceedingly characteristic owing to the dropping out of certain things, and other things being retained.

10,085. Can you detect this process of sorting by means of the mud?—I should say yes, in a measure at any rate; that is to say, in a short distance the yellow fibrous material, drops out and goes into the mud, and you lose it in the further deposits. The two things which are the most persistent are spiral vessels and this yellow amorphous material. Then comes a time when the spiral vessels drop out, and you get yellow amorphous material as the last remnant of sewage in the deposit.

10,086. And that is what you would expect to find at the furthest distance from where the sewage is poured in?—Yes, by means of this processs of sorting according to the specific gravity of the different bodies. The next point is the decomposition which various bodies undergo. As a matter of fact you can almost divide the Thames by means of the character of the Thames deposits.

10,087. The most resisting of these bodies being those to be found at the greatest distance?—Yes.

(*Chairman.*) Not the most resisting but the lightest.

10,088. (*Mr. Balfour Browne.*) Both are to be considered, both the specific gravity by which you get your process of sorting, and this resisting power by which you detect the spiral cells?—Yes, it appears to me that when you get a considerable distance from the outfalls there are two things, you get the yellow amorphous deposit and the spiral cells, and the last thing of all is the dropping out of the spirals. It would appear that the spiral cells drop out before the yellow amorphous material disappears; so I should say the last signs of sewage would be the yellow amorphous material. Then comes a very important point, I take it that the appearance of these two bodies, that is to say, the yellow amorphous material and the spirals in conjunction, is very important for this reason: that the spiral matter is of vegetable origin, and indicates to my mind, although not absolutely, yet almost absolutely, that the material has passed through the alimentary tract, whilst the yellow amorphous material is of animal origin; and so you get a combination both of animal and vegetable origin indicative of sewage.

10,089. Have you anything further to say with regard to the appearance presented by non-sewage mud?—I think I have almost said all I wish to say upon the subject. I wish to point out that on Diagram B, figure 4, there is yellow amorphous material and some vegetable matter, which latter was purely accidental.

10,090. You have not told the Commission, though I think it is printed upon the plate, where all these specimens were taken?—I think it is printed on Plate B.

10,091. Figure 1 at London Bridge, 2 at Blackwall, All Hallows Pier, and Chelsea?—Yes.

10,092. You say these figures X and Z represent sewage and non-sewage mud, where were those taken?—As matter of fact the one was taken opposite the intake of the West Middlesex Water Company; I have not a note of where Fig. Z. was taken. There is nothing very remarkable about it, but still I can get it for you before the Commission meet next time.

10,093. Now I will ask you this: from the Outfall Sewer to Bugsby's Reach upon the river can you tell, the Commission what is the character of the mud there?—May I put in a table at this point (*handing in Table No. IX*). This is an analysis of mud, I have nothing more to say about the analysis of mud, except that they were samples of mud sent to me, and clearly they are from the River Thames at different points. Looking at them and considering the quantity of organic matter they contain, and the quantity of nitrogen they contain, and the quantity of phosphoric acid they contain, I have no doubt of their being of sewage origin; that is to say, that they contain sewage. I do not say how much sewage, but merely that they contain sewage.

10,094. (*Professor Williamson.*) At what temperature was the substance dried?—They were all dried to 230° Fahrenheit. I would say that all the water deposits and everything of that kind are dried at that temperature.

10,095. How is the total amount of organic matter ascertained?—That is ascertained simply by burning; the ratio of nitrogen to carbon is estimated directly. As far as chemistry is concerned, I have no doubt that these muds contain sewage without saying anything about the proportions.

10,096. Under the head of phosphoric acid, here are figures for a certain way down the column and then blanks; were there no determinations in that case made?—No, they all came out very much alike, and they involved considerable labour, so I did not think there was any object particularly to be gained by continuing to make them. If I had found variations I should have gone on with them.

10,097. (*Mr. Balfour Browne.*) Now, have you anything more to say about the mud Table?—I want to say, that although the microscopic evidence is in no sense absolutely quantitative (which it is not) it is in somewise relatively so. For instance, I will give an illustration of what I mean in the case of spiral vessels. I have found spiral vessels at Hammersmith rarely, but I have found them occasionally as far as Battersea. Now comes the point, that up to Deptford they are fairly frequent, I might also say very frequent, I have no particular number to give for these places, you must take them generally. It is very difficult to say anything more than that they are very frequent.

10,098. Now I will ask you, as we are going down the river, have you ever found them above Hammersmith? Have you ever found them at Teddington?—No, I have not found the spirals at Teddington.

10,099. You have found some up at Hammersmith, and you have found them more frequently at Battersea, and more frequently at Deptford?—The way in which I would convey my meaning is, that from London Bridge to Battersea they are "occasional," from Deptford to London Bridge, "fairly frequent," but up to Deptford "frequent." I will give you from my own notes the result of the examination of the suspended matter of water. Particles of muscle are found tolerably frequently up to Woolwich; occasionally, but seldom from Woolwich to Greenwich, and not above Greenwich, except a mere isolated particle, which may be found now and then in any part of the river. Sometimes you may find a particle which may come in from other places, because there is other sewage coming in.

10,100. (*Mr. Bidder.*) This is striated muscle that you are now referring to?—Yes; this is striated

*Dr. C. M. Tidy, M.A., M.B.*

21 Feb. 1883.

muscle; when the striation is lost, you cannot find it at all. Then with regard to yellow elastic tissue, it is fairly frequent up to Blackwall, it is occasionally found between Blackwall and Bermondsey, and a few isolated particles in other parts. Shreds of fasciæ are not seen frequently above Blackwall; occasionally particles are found as far as Battersea. I am afraid this does not convey much information except that I see a larger number at one place than another. Then with regard to free spiral vessels in vegetable cells, these I have found as far as Battersea, and even Hammersmith. Up to Deptford they are very frequent; from Deptford to London Bridge fairly frequent, and from London Bridge to Battersea occasional. Then with regard to yellow amorphous matter and yellow masses, this seems practically to be the last remains indicative of sewage. I have found them as far as Chiswick, and so far as amount, is concerned, I should be inclined to think that the quantity present gradually increases as you approach the sewer outfalls at Barking. If I were to put it as I should be disposed to put it, it would be thus; that there is certain amount of indication of sewage in the higher reaches. Then the quantity gradually increases. We have amorphous material to start with, then we have spirals, then we get particles of fasciæ and tendon and elastic tissue, and then we get particles of muscle further down, till we get to the sewage outfalls; and although I cannot give you definite facts in proof, that seems to suggest not only an animal origin, but to plant the origin of the whole at the spot where you find the greatest number of particles.

10,101. (*Professor Williamson.*) Do you find that the organic matter in the mud keeps pace with the number of those particles in the microscope?—No, it is difficult to say the relation of the total organic matter to the total mud.

10,102. Does it appear, from your determinations of the proportion of nitrogenous matter in the mud, that a conclusion of the same kind as you suggest from your observations with the microscope is borne out by quantitative measurements, or does it not?—Whether the quantitative determinations of nitrogenous matter increase as you get nearer to the outfalls, in the same way as the various particles increase. I should not like to answer the question off-hand.

10,103. In your tables you have a larger quantity of organic matter in some parts than in others?—I do not think the question of the quantity of organic matter in the mud conveys much; it is rather the kind of organic matter that is important. I should prefer to regard the relation of nitrogen to carbon as the more important element in determining the character of the mud.

10,104. (*Mr. Bidder.*) Would you be able to tell us where the sample was taken which is marked "off Erith" in your Table IX.?—The question shall be answered.

10,105. (*Mr. Balfour Browne.*) Some of the samples of mud in this table you took yourself?—Some of the samples I took myself, and some were brought to me.

10,106. And you put them forward for what they are worth?—Yes.

10,107. You have summed up the result of your microscopic investigation, and you say you trace this impurity to the sewage outfall?—I think so; I do not mean to say that some of these things may not have come from elsewhere. I do not wish to imply that even in the most distant way, because I know the sewage gets into the river elsewhere, and I presume some of these things may get in in this way, but we know that we find the sewage matter, and the yellow amorphous matter, and the free spirals in the higher reaches. We know the yellow amorphous matters gradually increase in quantity, we find the free spirals also gradually increase in number, and we further find that as we approach the outfalls, we have added to these, other constituents of sewage, such as shreds of fasciæ and elastic tissue. Then, again, lower down we get particles of muscle joining the ranks of the sewage constituents of the suspended matter. It appears to me that there can be very little reasonable doubt, at any rate it is fair to assume, that the outfalls at Barking and Crossness may convey certain of their sewage constituents up the river.

10,108. Now, do both your chemical and microscopic researches show that the upper reaches are to some extent fouled by the outfalls?—I have not a doubt in my own mind that the Thames in the higher reaches is being rendered impure by the outfalls of the Metropolitan Board of Works; you can put it to yourself; 400 tons of material every day being discharged into the river, how can it do otherwise. It cannot do otherwise than foul it.

Adjourned to Tuesday next at half past 12 o'clock.

---

# TWENTY-FIFTH DAY.

## Tuesday, 27th February 1883.

PRESENT:

SIR P. BENSON MAXWELL, IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANCOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

Dr. CHARLES MEYMOTT TIDY, M.A., M.B., called again.

27 Feb. 1883.

(*Mr. Balfour Browne.*) There is one matter which Dr. Tidy ought to prove, and that is the question about the analysis of the water at Grays—at this instant he has not his figures before him; perhaps you would allow us to put that in afterwards.

(*Chairman.*) There is one matter I ought to refer to, and that is the effect of the sulphates in the water, which we thought ought not to be overlooked.

(*Witness.*) I would say that part of the smell is undoubtedly due to the reduction of sulphates, as a result of which sulphides are formed, the action of the carbonic acid on which sets free sulphuretted hydrogen. I wished to mention one other thing, and that was respecting the absence of hairs. I explained how I obtained the deposit, viz., by allowing it to stand in a glass, and then lowering a fine pipette and taking up a small quantity. I found, if hairs of any size were present, they would not come into the pipette at all, and therefore I got no hairs; and I have no doubt the explanation of that small hair of the mouse being found was that it was sticking upon end, or something of that kind, and was

therefore drawn into the pipette—probably that is the explanation of it.

10,109. (*Colonel Ewart.*) There is one question I should like to ask you—you spoke about the time of putrefaction of fœces, which you gave very generally; could you give the Commission anything definitely upon the notes as your opinion as to the normal time in which you may expect putrefaction to set in?—I cannot; it differs in different fœcal matter, and it differs so much according to the temperature of the day—in hot weather, for instance, the putrefaction would be so much more rapid.

10,110. What, should you say roughly, in hot weather, for instance, as to the time in which you would expect it to set in?—I will think that question over. I should not like to give an answer off-hand.

Cross-examined by Mr. BIDDER.

10,111. I think you and I were pretty well practised together upon a former occasion, and now perhaps we may be able to shorten the matter. I will ask you some questions at first with regard to the latter part of your evidence, that which related to the miscroscopical examination. I think I understood you to say frankly upon the last occasion that you do not pretend that that has any quantitative value?—Decidedly not; is is what is common to all microscopic work, that it is not quantitative.

10,112. I do not know whether you described your process so fully upon this occasion as you did upon the former inquiry—practically, you took about the size of a walnut of mud and stirred it up in a conical vessel, and then waited some four or five minutes?—No, I waited 24 hours in some cases.

10,113. By that time a certain amount of it had subsided?—Yes.

10,114. And upon the surface of that there was more or less a flocculent appearance?—Yes.

10,115. That you drew into the pipette?—Yes, I lowered the pipette on to the surface.

10,116. And, having done that, you examined it and obtained the results you described to the Commission?—Yes.

10,117. Whether that flocculent matter that you examined was five per cent. or one per cent., or less, of the total suspended matter, you have no means of ascertaining?—The microscopic examination gave me no information on the point.

10,118. You will quite understand I am not touching the chemical analysis. So far as that microscopic examination goes, in the examination you described upon the last occasion, where you found any traces of sewage, either recent or ancient, or more or less decomposed, whether that sewage was present in that mud or in the suspended matter in the proportion of one per cent or 10 per cent. or one-10th per cent., that examination gives no information whatever?—No.

10,119. Therefore I think, with one other question, I may almost pass away, without wasting much time over the microscopic examination; but I will ask you one thing, you described upon the last occasion how the striated muscular tissue is affected first, the spiral vessels being more permanent; and last of all, you say there remains nothing that you can regard as of sewage origin; but our old friend the yellow amorphous matter—you have no information there as to the time which is requisite to produce these successive changes?—No, I have none.

10,120. For instance, with regard to these observations, if we roughly say that the presence of striated matter indicates sewage of the most recent deposit, the spiral vessels more ancient, and the yellow amorphous matter still more ancient; whether that antiquity is a matter of hours, days, or months, the microscope gives you no information?—No, none at all.

10,121. I will only ask you one question in detail, and then I think you can pass entirely away from the microscope. I think you told us last Wednesday that the yellow amorphous matter you had traced up to Chiswick; I think that was your statement?—Yes, in the suspended matter.

10,122. I think, if you will recall your evidence upon the former occasion, the Mud Inquiry—you will correct me if I am wrong—upon that occasion you traced it up to Teddington?—That had to deal with the muds; what I am referring to here is the suspended matter in the water.

10,123. It will be interesting to make a note that in the mud upon a former occasion you traced the yellow amorphous matter all the way up to Teddington?—That is so, and that this time in the suspended matter I traced it up to Chiswick.

10,124. I will endeavour, I think, as far as I can, in passing over the other parts of your evidence, to follow the order in which you gave it; you put in a good many tables, and I think one of those which you put in first, and which has a certain importance as bearing upon the tables which have been put in by the engineers, founded on chlorine, was a table of analyses of sea water; it is No. 4 in the tables which have been put in by the witness; you there give analyses of sea water at different places?—Yes.

10,125. There is one sample, I suppose, that we may put aside, though it has an interest of its own, but not in relation to this case, and that is the Dead Sea?—Perhaps.

10,126. Now I will ask you this, have you confidence in the accuracy of these results?—Do you mean of these determinations of chlorine?

10,127. Yes?—I have to within one per cent. or I would say to within two per cent. I would say that the question of the determination of chlorine where there is a very large quantity present is admittedly a difficulty, but that, if special care be taken, I believe it can as a rule be brought up to within one per cent., and invariably up to within two per cent.; that is the way I should put it myself. I am quite ready to admit a slight error in those determinations.

10,128. I am not talking about one or two or five per cent. now, but one or two things catch my eye. The Mediterranean is represented as having a very high quantity of chlorine. I suppose we know the reason of that; that is, that the evaporation is very much greater than the introduction of fresh water?—Yes; it has also a very large quantity of solid matter.

10,129. Now at Southend you have a considerable admixture of river water?—Yes.

10,130. If your table is true, the water in the river at Southend at high water, take June 10th 1882, is more saturated with salt than in any known place in the world, except the Dead Sea?—You must not say, "any known place in the world"; you may say, "any places mentioned in the table."

10,131. I withdraw the term "any known place in the world." I will put it, "any place mentioned in the table"?—That was an extreme expression that you adopted.

10,132. I withdraw it freely. Now the sea at high water at Southend is more saturated than any place of all those you have selected in all parts of the world except the Dead Sea?—So it is.

10,133. Do you believe it?—Yes, I know it is correct.

10,134. Notwithstanding the large amount of fresh water admixed with it?—Yes, I know it is correct.

10,135. I wish now to draw your attention to this, that even at low water, when there is a far larger admixture of fresh water with it, it is far more salt than the Mid-Atlantic, and salter than any of the other places mentioned in the table, except the Mediterranean?—Yes, that is so.

10,136. Do you believe it?—Yes.

10,137. How do you account for it?—I cannot give the reason for it. I know it is the fact.

*Dr. C. M. Tidy, M.A., M.B.*

27 Feb. 1883.

10,138. Do you mean to say that the water at Southend at the period of low water is more briny than the water in the Mid-Atlantic, for instance, or the sea at Brighton, or the sea at Margate, and equal to the sea at Penzance?—I say what I know is a fact, that on June 10th 1882 the water at Southend at high water contained more salt than the sea of the Mid-Atlantic on the day when that sample was taken, viz., January the 28th 1882; that is what the table tells you, and nothing else.

10,139. But I did not select those places, you selected them yourself. Now I ask, is it credible that the water at Southend at low water should be salter than the sea in the middle of the Atlantic?—It is certainly credible; it is the fact.

The *Chairman* intimated that the credibility was a question for the Commission, the witness having stated that that was the fact.

10,140. (*Mr. Bidder.*) Now I will ask you this; apart from these analytical results, do you think or would you expect to find the water at Southend at low water salter than the Mid-Atlantic?—I am only discussing it from my own facts. I am perfectly certain that this is the fact and that upon the day in question it was so.

10,141. Will you just be kind enough to answer my question, putting that observation aside; would you expect to find the water at Southend at low water ten per cent. more salt than the Mid-Atlantic?—But there are so many things in nature that you would expect to find that you do not find. That is the simple fact, and I tell you the simple fact that the water at Southend at high water contained 1,558 grains on the day it was taken, and that upon January 28th it contained in Mid-Atlantic 1,261 grains.

10,142. You are not surprised at it?—I am not surprised at anything.

10,143. Do you give any explanation of it?—I do not profess to give any explanation of it. I tell you that it is the fact.

10,144. Was the analysis made by yourself?—Yes.

10,145. Just to come back to the high water at Southend. We have been told a good many times, you know, that the standard sea water contains 1,961 parts in 100,000; if you will be good enough to turn that 1,558 grains per gallon into parts to the 100,000, how many is it?—2,225.

10,146. So that it could only be produced by taking standard sea water, and evaporating it until it had lost a tenth part of its bulk?—I do not understand what you mean by "standard sea water." I never used the phrase.

10,147. It has been used by a good many gentlemen here; it is not my phrase?—I never used the phrase "standard sea water." I never said that standard sea water contains 1,961 grains.

10,148. I daresay you can tell me how much salt that represents, because that 1558 grains is merely chlorine. Take it in grains to the gallon. (*The witness made a calculation.*)?—It is about 2581.

10,149. So that, if our total of solid matter was right, that is almost the entire solid matter contained in it?—Very nearly. I do not think that is quite the fair way to put it, because I do not say that the chlorine is there as common salt. I never said so. You asked me how much salt that would amount to, but I did not say it was there as common salt.

10,150. Then the chlorine does not indicate common salt; it may be there free?—No, not at all; it may be there as chloride of magnesium.

10,151. (*Chairman.*) Can you tell me this; it was at high water that you took the sample which showed 1558 grains, was it not?—Yes.

10,152. It is perhaps rather a geographical than a chemical question, but would you expect to find in that sample very much fresh water, seeing that the tide flows in from the north?—No, I should not from that point of view.

10,153. (*Mr. Abernethy.*) You see it is a very large funnel-shaped mouth, and that the tide comes in from the North Sea; would you expect to find much fresh water?—No, I should not. As a matter of fact, I should expect to find very little.

10,154. (*Mr. Bidder.*) You would expect to find at high water, with the tide coming in from the North Sea, no fresh water at all?—No, I did not say that; I said I should expect to find very little.

10,155. Would you expect to find any, or would you not?—I would expect to find very little.

10,156. If that be so, what becomes of the tables the engineers have put in, and their assumption that the water which flows past Southend Pier at high water contains as much fresh water almost as the water that flows down?—I am not dealing with the engineers' tables.

10,157. All Mr. Mansergh's and all the other tables are based upon the assumption that the water in the reach above Southend had that amount of fresh water which is due to the difference between the sea water and the sewage water and the water at Teddington. For instance, upon the 30th November Mr. Mansergh gives the absolute high water, and he gives the sixth division below Crossness, which is from Southend to five miles up. He gives in Table M 3 c the total content of the river, and he informs us that this section contains 13,686,657,600 cubic feet, and in column 6 the percentage of that which is fresh water is given as 13·70; that is what his table is based upon. He assumes that that has come up from below?—I have not considered it from that point of view.

10,158. No doubt, but it is interesting to see how the two sets of observations clash?—That is a subject which the learned Counsel no doubt will deal with.

10,159. Then I will ask you this: if Mr. Mansergh is right that there is 13·70 per cent. of fresh water at high water at Southend, it can hardly be consistent with the water being as salt as the sea in the Mediterranean?—I should like to consider that question before answering it; I have not considered it, and therefore I cannot give the answer off-hand.

(*Mr. Lumley Smith.*) You are comparing different dates; that table is dated 29th January.

(*Mr. Bidder.*) But Mr. Mansergh is dealing with various dates, and upon every occasion he assumes a certain percentage of fresh water.

(*Chairman.*) 1785 is the amount of chlorine determined by analysis.

(*Dr. Stevenson.*) That is, parts per 100,000.

(*Mr. Balfour Browne.*) Dr. Tidy's figure upon the 100,000 parts works out at 2,225.

(*Witness.*) As a matter of fact, I have not compared these tables at all. I have started entirely upon my own experiments.

(*Mr. Bidder.*) Do not let me be supposed to suggest that, because upon the 30th of November this gentleman, Mr. Mansergh, estimates that there is 13·7 of fresh water, that is necessarily the percentage every day; it will vary with the amount of land-water coming down the river.

(*Chairman.*) Upon the 14th of September the chlorine found by analysis is 1931 in 100,000 parts.

(*Mr. Bidder.*) That is a long way short of 2225.

(*Chairman.*) I am only showing how far it varies—whilst upon the 30th of November there were only 1522 parts.

(*Witness.*) I should like to point out that upon October 16th at high water I found 1930 parts in 100,000, that is 1351 grains in the gallon.

10,160. (*Mr. Bidder.*) Your dates do not synchronise exactly with the engineers' dates?—No, they do not.

10,161. Now I want to go on to a matter of more immediate importance with reference to the question of pollution. I think I understood you to say the other day that you did not place any confidence in the amount of the oxygen required to oxidise organic matter as a test?—I said I had not used it in this analysis, owing to the presence of a very large quantity of chloride of magnesium in the water which un-

doubtedly interferes with the action of the permanganate on the water.

10,162. Other chemists have given some evidence, I think, to the effect that there is a way of applying that test notwithstanding?—I do not mean to say that there may not be, for I have worked at that question of the oxygen required to oxidise organic matter as much as most people, and I am perfectly prepared to meet the difficulties which occur.

10,163. Upon the albuminoid ammonia there is no reliance to be placed?—No.

10,164. And upon the proportion or ratio of the nitrogen to the organic matter, that you have dropped?—I do not quite understand your question, because I have stated it certainly over and over again in these tables.

10,165. I mean the proportion of nitrogen to organic matter, not nitrogen to carbon?—Seeing that it is impossible in the water to estimate the total organic matter, it is totally impossible to say what is the ratio of the nitrogen to the organic matter.

10,166. You have given that up?—I never gave it.

10,167. Did you not do so upon the last inquiry?—Pardon me, that had relation to analyses of mud, and not to analyses of water.

10,168. Up to that time you thought that the ratio of nitrogen to organic matter in the analyses of mud was a matter of much importance?—I first thought it was of importance.

10,169. And you afterwards thought it was of very little importance?—That was a question of mud, and this is a question of water.

10,170. You gave it up?—Yes, I did, in the mud, but not in the water.

10,171. Now, if I do not misinterpret your evidence, the main indications upon which you put reliance now are the oxygen in solution and the ratio of nitrogen to carbon?—No, those are not all; I have certainly said a good deal more than that.

10,172. Are those the principal ones?—It is difficult to say are principal ones.

10,173. I will put it interrogatively, as I have not gathered it apparently from your evidence; what do you rely upon as the principal trustworthy indications of pollution?—I will go through them.

10,174. Take that great Table No. 1, and point out, if you please, to the Commission, and to me which out of all the results which are recorded there are those upon which you mainly rely as indicating pollution?—First, on the total organic carbon present.

10,175. That is the most important, is it?—I am not putting it in that way, you can never regard an analysis and say, this thing is of the highest importance, and this is of the second importance.

10,176. Put it in your own way.

(*Chairman.*) I thought you made a statement upon this point before, and that I had a note of it?—I said the points upon which I specially relied were, firstly, the total organic carbon; secondly, the total organic nitrogen; thirdly, the ratio of the nitrogen to the carbon; fourthly, the free oxygen; and fifthly, the ammonia.

10,177. (*Mr. Bidder.*) I do not recollect that you put forward the total organic carbon or the total organic nitrogen by themselves, as being an indication of sewage pollution?—The quantity of organic matter.

10,178. As arrived at by the combustion process?—Yes, I think I told you the total matter; the organic nitrogen and carbon was an index of the quantity, and the ratio was an index of the kind; I stated that distinctly.

10,179. Your first is, total organic matter, as arrived at by C+N?—Yes.

10,180. Secondly, the ratio of nitrogen to carbon as indicating the kind of pollution, animal or vegetable?—Yes.

(*Chairman.*) If you refer to question 9843, I think that is about the part of the evidence where the witness stated what his points were.

10,181. (*Mr. Bidder.*) Pardon me for a minute if I take them in a somewhat different order from what you put them in?—I think it is immaterial myself, so I shall not quarrel with that.

10,182. I will go first to the question of the free oxygen; you told us, I think, that you took as your standard, to compare with these polluted or suspected examples, normal river water?—Normal Thames water.

10,183. The normal Thames water should contain two cubic inches of free oxygen to the gallon?—I did not say it should, I said it did.

10,184. Is it the fact that your own observations show you, and satisfy you, that that is only true in the winter, and that in the summer the proportion is a little more than half that?—It is so, you are perfectly correct there, I said as distinctly as I could that the quantity of free oxygen varied with the season, or, in other words, with the temperature.

10,185. Forgive me for reminding you that the only figure you mentioned to the Commission as the standard was two cubic inches to the gallon.

10,186. (*Chairman.*) Question No. 9848 refers to that point?—I should be very happy to go through a huge body of results if you wish it. I think I may give you the facts upon that subject. The question is, does the free oxygen in the river vary; to that I say, it does, and I am now going to deal with the facts bearing upon the question.

(*Mr. Bidder.*) That is not what I asked.

(*Chairman.*) You did suggest that he mentioned a figure which it might be imagined was particularly favourable to the view he took of this case, whereas he had suppressed other figures.

(*Witness.*) That was my impression.

(*Chairman.*) I think that is the view you took of the question, but it will be time for you to do that when your counsel re-examines you.

10,187. (*Mr. Bidder.*) I will give you an opportunity of doing it before I pass from the subject. I will promise that you shall have that opportunity. I never take an unfair advantage of a witness. Now, is not this first what you did say, that the Thames river water contains about two cubic inches, which varies, however, with pressure and temperature; that is, at 9848?—Yes, and I said so. I made the statement that normal Thames water contains about two cubic inches of free oxygen per gallon. That statement was made on the results of between 4,000 and 5,000 analyses which have been made during the past two years and a half. It is only during that time that we have had a method suggested of correctly estimating the free oxygen in water; that is to say, in such a way that we can use it. Practically, we had methods of doing it before, and although upon previous occasions, in a report which I published, I gave some analyses of the gases dissolved in Thames water, it was on a comparatively few experiments. Since then, as I say, I have made an enormous number of experiments, of which I have the results here.

(*Chairman.*) I think it will be time enough afterwards if we should require them.

10,187*a*. (*Mr. Bidder.*) I do not wish there to be the slightest ground for saying that I interrupt you, but if every question is made the subject of a long essay, your evidence will take a very long time. At question 9848 I have exactly what you did say. "It is some-
" times as low as $1\frac{9}{10}$ths of a cubic inch per gallon,
" but it may be said generally that the water of the
" Thames contains two cubic inches of free oxygen
" per gallon. It is sometimes 2·2, it sometimes
" goes down to 1·9 and even to 1·8 of free oxygen
" per gallon"?—Yes.

10,188. Now I will draw attention to what you have said in a report or pamphlet published by yourself very recently, and laid before the Chemical Society 1880—that is not quite before the flood, you know. You there say, "The only point worth remarking
" is that the oxygen in solution during the winter
" months was found to be very nearly double the
" amount found in solution during the summer months,
" or exactly 2·19 cubic inches in the winter, against
" 1·19 cubic inches in the summer"?—I think it is

*Dr. C. M. Tidy, M.A., M.B.*

27 Feb. 1883.

right to say I have explained that it is only within a very short time that we have had a method that Schutzenberger suggested, which is the process by which we do it now.

10,189. Would you say that in 1880 chemical science was in such a crude condition that you did not know how to estimate within 50 per cent. the amount of free oxygen in water?—No, but I would say that we used not at that time to estimate the amount of free oxygen in water, except incidentally.

10,190. Had you not at that time, as this table shows, in 17 analyses during the summer months, from May to October, obtained the result of 1·19 cubic inches, while in 10 analyses, made in the winter months, you got a result of 2·19 inches?—Yes, I do not dispute that at all.

10,191. Now, whatever may be the progress of science, in 1880 you were able to find two cubic inches when it was there, and your analyses up to that time show you the fact that, whereas you could find two cubic inches and upwards in the winter, in the summer you could only find one?—I can only say I got this result at that time, and that, by an improved process of observation (which is a very fair thing to say) on a very large number of experiments, I got a very much larger quantity.

10,192. But is it "a fair thing to say"; surely the process of 1880 was good enough to compare the results of one time of year against another, and the same process you tell us gave double the result in winter that it did in the summer?—I am bound to say I do not believe the oxygen did go down to 1·1; I do not believe it.

10,193. Then you do mean to say now that you place no reliance upon the process by which you found two cubic inches in the winter and only one inch in the summer?—I have altered my opinion subsequently.

10,194. (*Chairman.*) I understand you to say you have made these two sets of experiments by two different processes?—Yes.

10,195. Which do you consider the more reliable?—The present one.

10,196. If the former statements differ from those results you obtain now, do you place any reliance upon them?—No, I do not. I prefer to adopt the present process.

10,197. (*Mr. Bidder.*) You are satisfied that the results you obtained in 1880 are worthless?—No, not at all.

10,198. (*Dr. Stevenson.*) Would the older process furnish you with comparative results; would the summer and winter results compare with each other?—Yes. I may say that every fourteenth (I used to make every tenth), but every fourteenth, experiment is now estimated actually. I quite admit that the Schutzenberger process does give a slight error, and I know the error that it gives, but it is not of any moment.

10,199. But does the old mode you spoke of give comparative results, or does it give fallacious results?—There is no secret in the way these former analyses were made; the water was taken and boiled, and, the oxygen being collected in a Cooper's tube, a piece of potassic hydrate was put in to absorb the carbonic acid, and some pyrogallic acid added, by which the oxygen was then absorbed.

10,200. But do you think that the results of the analyses in summer and winter could compare with one another?—I should be sorry to say exactly, but I should think they ought.

10,201. (*Dr. de Chaumont.*) You mentioned that in every fourteenth experiment the oxygen was determined absolutely; will you tell the Commission how that was done?—It was done by boiling, but I did it by means of a pump.

10,202. Did you determine it by way of the pyrogallic acid?—I now measure it in one of Dr. Frankland's gas apparatuses, which I did not use before. I used in the old experiments an ordinary bent tube—a Cooper's tube—it is only within the last two years that I have estimated the free oxygen in every water.

10,203. But it is older than that?—The process is.

10,204. (*Mr. Bidder.*) It is the fact, is it not, that sea water contains much less free oxygen than river water?—No, that is not so, it is a little less undoubtedly, but not much.

10,205. You said, I think, that it varied from 1·7 to 2·1?—Yes, but I could only give you the observations made upon the water at Brighton, as that is the only opportunity I have had to examine it in any detail. I stated that over 50 determinations were made of the water at Brighton, and it varied from 1·7 to 2·1; practically it was two cubic inches.

10,206. By-the-bye, before I go on to another point, of course, if there were any foundation at all for, or any correctness in, this statement you made in the pamphlet, that, in the summer months, the quantity of free oxygen falls to something very much below the two cubic inches, it would not be fair to draw the deductions which you did from the percentage of oxygen in the Tables here?—Manifestly not, but I should like to say that all the deductions have been drawn upon experiments made in the same way.

10,207. Do I understand you to say that the more recent and improved method of the last year or two, entirely or substantially, negatives the result that was then stated, that in summer the oxygen in solution falls to very nearly half of what it is in winter?—I should not like to say that, I wish to say that by the method adopted now, I never get at anything like 1·1 in Thames water above Teddington.

10,208. Would you kindly tell us with your improved methods and increased science what you do get it at?—I will take it for last year. I will take January 1882.

10,209. Could you give us without giving the detail, the average result of a large number of summer, and the average result of a large number of winter observations?—Will you allow me to read you seven numbers which are the averages of a large number of observations.

10,210. You may read anything you like?—During the month of January we got 2·22, 2·08, 2·15, 2·15, 2·20, 2·16, and 2·20. Let me say that these results Dr. Odling is responsible for as well as myself.

10,211. Now take July—let us go to a corresponding summer month?—In the month of July I have the following figures 1·80, 1·66, 1·81, 1·78, 1·78, 1·81, and 1·76.

10,212. That sounds like an average of about 1·75?—Yes, 1·75 or 1·80. Now the next month, 1·79, 1·73, 1·80, and 1·81.

10,213. That is again very nearly 1·75?—Then when we get to September it goes up again, 1·90 and 1·81.

10,214. So that for the purpose of comparison, at any rate the 2 cubic inches must be brought down to 1·75?—No, say 1·8. If you take the average of the year it comes to about two cubic inches per gallon.

10,215. I entirely decline to take the average of the year when discussing summer samples; these samples in your Table 1 are taken in the months of June and July?—I think you are quite right there.

10,216. So it comes 1·75 as the result of your more recent observations. In fact your table itself shows upon the face of it (I am still upon the first table) that that is about the best result, taking the average of them, that you get up at the head of the river; Teddington, and about there some are a little more and some are a little less?—Yes, I think that is so.

10,217. Now I go to a point I touched upon prematurely. Do you agree with me, that if it were the fact that oxygen in solution in sea water were much less than in river water, as you go down the river and get an admixture of sea water, you ought to get a continual diminution of the amount of free oxygen?—Manifestly, if the quantity of oxygen in sea water was less than in river water.

10,218. Practically, you say it is not?—I say that my own observations have led me to say it is not.

10,219. Is that quite so; let me draw your attention

to your own Table 10. The water you told us a little time ago at Southend Pier was practically sea water?—Yes.

10,220. Now I will draw your attention to Table 10, and that shows that at Southend Pier at high water, when we are supposed to have practically pure sea water, according to you?—I did not say so.

(*Chairman.*) It was I that suggested that.

10,221. (*Mr. Bidder.*) You see the fact that your own analysis finds at Southend Pier at high water 1·39 at the bottom and 1·31 at the surface?—Yes.

10,222. Now be that mixed, or be it pure sea water it is the water that feeds the Thames above Southend Pier, is it not?—Yes.

10,223. And as that has only two-thirds of the quantity of fresh water that you say is pouring in at Teddington, you ought to expect a constant diminution of the quantity of free oxygen as you go down the river?—Yes, to that extent, no doubt.

10,224. But it is a substantial extent, because it is only two-thirds of it?—It is perfectly manifest that upon that date there was less free oxygen at Southend than at Teddington.

10,225. But it is your own analysis; it is not mine.

(*Chairman.*) What is the amount of free oxygen as a general rule in salt water, you said it was a little less; how much less is it?—It varies somewhat; 50 determinations of the oxygen were made of the water at the West Pier at Brighton; that is really the only basis that I had to go upon, and it varied from 1·7 up to 2·1 cubic inches. There were one or two numbers, such as 1·69; but, omitting those which I think I have the right to do for certain reasons, I think you might take it from 1·75 to 2·1.

10,226. Are those the averages?—No; those are the extremes; but it is right to say that that was entirely upon the one water which I had the opportunity of examining.

10,227. (*Mr. Bidder.*) For our purpose in discussing the estuary of the Thames above Southend, and its condition, why is not your observation at Southend Pier at least as reliable a one as the one taken at the end of the West Pier at Brighton?—I did not say it was not.

10,228. It is more valuable, is it not, for this purpose?—I am not discussing that.

10,229. This element of free oxygen is also liable to very violent fluctuations, is it not, without apparent cause. Of course everything has a cause if one only knew it; now take your Table No. 5 at Chiswick, I see your free oxygen upon the days you took it, the 16th and 17th, dropped at 11 at night from about 1·7 and 1·6 to 1·2, can you account for that?—It is very difficult to explain some of these things. It is possible that at that time the action of vegetation may be less.

10,230. Before we come to the table in which you charge the diminution of oxygen entirely to us it is a fact, is it not, that at one place, viz., Chiswick, far or remote at any rate from our influence, you have fluctuations to the extent of 33 per cent. in the amount of oxygen within a few hours?—It is perfectly true I did get these fluctuations, and it is right to put these fluctuations in, you must take them as they are.

10,231. Again I go to another part of the river, Table No. 17. Now here we have a very different part of the river, and in the samples of the water at Erith I find there are very astonishing and rapid fluctuations?—There are very remarkable variations.

10,232. Now what you would expect at Erith, (Erith being below the outfall a few miles) would be a diminution of the amount of oxygen at low water and an increase of oxygen at high water?—Yes.

10,233. Will you tell me shortly, if I am not right in saying that you very often find that exactly the opposite thing happens?—Yes, I am bound to say that Erith is one of those places which has somewhat surprised me over and over again. I think it right to say I have many results from the water at Erith which are very incomprehensible. I quite admit all these great variations.

10,234. Now I will ask you this:—does not the admitted liability to such gigantic variations which, as you properly say, are quite incomprehensible, shake your reliance upon the influences and deductions from the Table?—Yes, it would, if the inferences were drawn from a single place or determination, but in recording the analyses you cannot take one single thing and draw deductions, you must take several things.

10,235. You have not marked high water upon that paper, but I suppose one may pretty fairly infer from the amount of total solids, which was high water and which was low?—Yes.

10,236. Take October the 30th, at 10 a.m. and four p.m. I am not wrong, am I, in assuming that at 10 a.m. when you found 70 grains of solid matter in the water, it was low water?—Yes.

10,237. And that four p.m. when you found 273·30 grains it was high water?—Yes.

10,238. At 10 a.m. there was 1,848, a very fine supply of free oxygen and that that dropped down to 1·518 at high water?—Yes.

10,239. According to your views that is quite the opposite of what ought to occur?—Yes, I quite admit that it is not what you would expect.

10,240. But I am putting it to you, is it not diametrically opposite to what you would expect?—I am sorry to say you very often find results diametrically opposite to what you would expect.

10,241. Then I will pass from that for a moment; now I will ask you another question about the oxygen in solution. I am coming to the results in Table No. 1. I assume you did not take the samples yourself?—I took every sample in the table myself, except two; I think I have mentioned that circumstance before.

10,242. The process, as I understand or the method of taking samples and subsequent proceedings were that you filled a bottle with the water, you stoppered it at once, and took it home and examined it within 24 hours?—Yes, for the free oxygen.

10,243. I suppose, if your hypothesis was right, that in certain cases the water which you took was polluted water containing oxidisable sewage matter, that in the 24 hours it was standing, that oxidisable sewage matter necessarily took up a certain quantity of the free oxygen?—Yes, it may have done so, but I think I explained that, as far as my experience went, if you filled a bottle quite full, and then put the stopper in, so as to prevent any shaking about of the water you would reduce the oxidation in the bottle to a minimum. I am quite ready to admit there may be an error, but it is a very small error, if it is analysed shortly after the sample is taken.

10,244. Either the water contains no putrefiable matter, or if it does contain oxidisable and polluted matter, it is reasonable to expect that some of the oxygen will, in the 24 hours, have been absorbed?—Yes.

10.245. Have you any experiments which tell you the time within which the action will take place?—I could give you some results, and I will tell you how I have arrived at them. I have done it first by estimating the quantity of free oxygen in the water taken at the moment, and then in the water after 24 hours of the same samples, and I have found the results very nearly identical. I am going to give you one or two cases in point inasmuch as your question has raised a very very fair question. First, as regards a water containing a large quantity of vegetable matter, a very great number of those observation were made upon the water of the Shannon, where I had an opportunity of estimating the free oxygen in the water as I looked it out of the river directly, and then from samples of the same water after it had been out of the river some time; although I admit the quantity was a little less undoubtedly in the latter case, yet it was very slightly less, and not a point to make a difference of.

10,246. (*Professor Williamson.*) I wish to ask you whether that was water containing organic matter similar to that which is supposed to be in the Thames, or whether it was peaty matter?—I was trying to give

*Dr. C. M. Tidy, M.A., M.B.*

27 Feb. 1883.

an illustration of the two kinds of water; first, as to vegetable matter and then as to animal matter. Now the results of the second experiment also coincided with those upon the water of the River Shannon. There is a small cutting which receives a considerable quantity of sewage from a little town south of Lough Derg, called Killaloe. It is a small cutting from the main river. I had occasion to examine that very closely, and there was some sewage, organic matter, going into the river I cannot tell the quantity, but, at any rate, the oxygen there is reduced to a very small quantity. There again, being in a boat upon this river, I estimated the oxygen in this water very carefully on the spot, and then took a sample back and estimated it again. I admit again, that the quantity of the free oxygen was less in the subsequent examination, but it did not amount to any alteration in the first place of decimals.

10,247. (*Professor Williamson.*) Was that in the summer or winter, was it warm or cold weather?—That was last August.

10,248. It was in hot weather, then?—Yes. Now, although I admit there is a slight difference, it is not one which makes any difference in the first place of decimals, but if you do not fill the bottle, if you leave a part empty at the top, and shake it about and take it home, then it does make a difference.

10,249. (*Mr. Bidder.*) Then there is another cause, there is oxygen in the air of the bottle?—You get the mechanical action, I think.

10,250. Now I am going to ask you what may appear to be a stupid question. Supposing you put into a bottle of water, say of Thames water, containing free oxygen, five per cent. of fresh sewage, and cork up that bottle, why should the sewage in the water oxidise more slowly so long as there is oxygen to take up, than if it were in the river itself two or three feet under the surface?—There are a good many difficulties in that question. It has been under discussion a good many times. I have always held (though it is a subject upon which Dr. Frankland and myself have not absolutely agreed) that it is not possible in the laboratory by shaking up water in a bottle to imitate what is going on in nature; in the first place, there is no vegetation in the bottle and you lose the chance of setting free oxygen in a somewhat hyper-active condition.

10,251. Have you ever tried any experiments at Barking with the Thames water with the London sewage in it, with the view of ascertaining what is the amount of free oxygen in the water?—Yes, many.

10,252. (*Dr. Stevenson.*) You spoke of a particular water in a cutting of the Shannon which included animal matter, what initial proportion of oxygen was there when you took your samples?—I cannot give it you at the moment.

10,253. It was very small, was it not?—It was very small, but it will be one of those points to which I shall have to refer, as well as the point upon which the learned Commissioner asked me a question about the activity of oxygen in different quantities.

10,254. (*Mr. Bidder.*) With respect to the Shannon observations, I do not quite understand how you were able to estimate at the time in the boat the quantity of oxygen in the water?—I had all the apparatus. I have a box which holds everything necessary for the estimation of the free oxygen, and I make a point of always taking it with me when I am engaged upon this kind of observation.

10,255. Is this a recent observation?—Yes, it was taken last year.

10,256. Were you all agreed that fresh sewage matter does oxidise, and in oxidising necessarily does take up oxygen from the water of the river?—There can be no doubt about that.

10,257. There can be no doubt that you must find lower down in the water of the river in which the sewage is placed a certain diminution in the quantity of free oxygen?—Exactly.

10,258. The very fact of finding a diminution in the quantity of free oxygen is a sure indication that the river has been doing its work in burning up the sewage?—I think so. If you find a small quantity at one spot and lower down you find more oxygen, it either means that water has come in containing a very large quantity and so has raised the total, or it may be that the river has done its work and is recovering itself by becoming a little more oxygenated; you must not take either view too precisely.

10,259. But taking a case like this where the river you say above Barking contains a considerably larger quantity of oxygen, and by the time it has flowed down to Erith, and has got the sewage in it, there is a considerable falling off in the oxygen, that is *pro tanto* an indication that the river has been doing its work, that is to say, burning up the sewage?—Yes.

10,260. Subject to the other observations I made some time ago, that there is a certain diminution due to the admixture of sea water?—Yes, that is what I said just now.

10,261. But I make reference here to the very rapid diminution which takes place in the river where the proportion of diminution due to the admixture of sea water is not great?—Yes, that is so.

10,262. Now when you come down to ·6, and ·5 of an inch to a gallon at Crossness, that throws some light, does it not, upon another element upon which the river-side gentlemen have been very profuse in their eloquence, namely, the absence of fish in the water in that part?—I do not know the quantity of oxygen which is necessary to maintain fish in water.

10,263. When you find that the quantity of oxygen has been reduced to a third of the normal, it may be sufficient to indicate that it is insufficient to support the life of fish?—Yes, but you are regarding the free oxygen as if that were the only constituent of the analysis.

10,264. Not at all; we have had 50 gentlemen describing the great paucity of fish in that part of the river, and Lord Bramwell thought I was putting a paradox when I said that that did not necessarily suggest there was any poison in that part of the river?—Quite admitting that the diminution of oxygen may materially influence fish-life, although I do not know how much oxygen is necessary to do so, yet, quite admitting it may be so, we have set free by the reduction of the sulphates of the water and the action of carbonic acid on those suphides so formed, a gas which is undoubtedly infinitely more deleterious to animal life than the mere reduction of the free oxygen.

10,265. If a gentleman were found in a hermetically sealed room lying dead and you found there was no oxygen in the air, you would not go about to look for prussic acid, would you?—My own experience of forensic cases leads me to say I should; I never believe that the apparent cause is the real cause.

(*Chairman.*) If you put in something which takes all the oxygen out of the water, and makes it unfit for the maintenance of fish life, I suppose the unfitness of the water for fish life would be due to that which you had put in, which had consumed the oxygen.

(*Mr. Bidder.*) Undoubtedly, but I am suggesting at once that the water is inimical to fish life because the sewage has taken away the oxygen; but at the same time you must not draw the inference that there is anything actively poisonous in the water.

(*Chairman.*) You take away an element which is necessary to life.

(*Mr. Bidder.*) I do not admit that that is the sole cause.

(*Witness.*) It is the setting free of the sulphuretted hydrogen from the reduced sulphates of the sea water, which sets free a noxious gas which is itself a very active poison; it is not necessarily the taking away of something which is necessary to life but it is putting in what is actively inimical.

10,266. Have you any observations as to the poisonous effects of the actual sulphuretted hydrogen?—No, I have not here.

10,267. You have yourself told me that you were very much struck, in examining the muds in this part

of the river, with the absence of smell?—Very often that is so, but at the same time I do not say I have not smelt a smell over and over again.

10,268. Now let us go to another point; the ratio of the nitrogen to the carbon, as I understand, and you will correct me if I am wrong, your views are these, that the ratio of nitrogen to carbon is an indicator of the source of the organic matter and that the rise in the ratio of nitrogen to carbon indicates animal rather than vegetable origin?—It is the larger quantity of nitrogen in the organic matter which is so indicative.

10,269. Is that a fair inference in things like this, where you are dealing with a tidal estuary; have you not already told us that the sea water itself contains a very high ratio indeed of nitrogen to carbon?—Yes, I have admitted that.

10,270. It is 1 to 1·5?—Yes, quite so.

10,271. And therefore, as in the case of the free oxygen, it necessarily follows that if there were no sewage and nothing of that kind polluting the river, inasmuch as, as you go down the river you increase the proportion of sea water, you ought to find the ratio of nitrogen to carbon rise?—Yes, I have said so.

10,272. Is it not the case that the admixture of sea water, having regard to the high ratio you have spoken of, is quite sufficient of itself without anything else to account for the rise which you have in this table of the ration of nitrogen to carbon?—I have not regarded it from that point of view.

10,273. I ask you is it not the case?—I cannot answer that question.

10,274. You find a certain rise in the ratio of nitrogen to carbon; do you account for it by assuming that it is produced by the admixture of an ingredient, that is to say sewage, in which if I recollect rightly you say the nitrogen to carbon is in the proportion of 1 to 1·6?—But I never accounted for the rise in the ratio of nitrogen to carbon entirely by the addition of sewage.

10,275. Then I will withdraw that. I think I understand you to say that the rise of the ratio of the nitrogen to carbon indicates to your mind organic matter of animal origin?—Yes, I will accept that. You are now putting it as an abstract point. I admit it.

10,276. That is its value in discussing these tables of yours?—Manifestly.

10,277. And that is what you rely upon?—No, I do not rely upon any one thing specially.

10,277*a*. Do I understand you to suggest to the Commission that the progressive rise in the ratio of nitrogen to carbon, which you find as you go down the river is (among other things if you prefer) an indication of an increasing pollution of animal origin?—Yes, one of the things suggestive of it.

10,278. Is it not equally accounted for by the presence of sea water?—Yes.

10,279. (*Mr. Lumley Smith.*) You will find that in the answer to question 9,892?—I explained that very fully upon the last occasion.

(*Chairman.*) The question was "then the ratio of nitrogen to carbon is as 1 to 1·77," and the answer was, "Yes. (*Q.*) That is very different from what you "find in the pure water? (*A.*) It is very different "(*Q.*) It is more like what you get in sea water. (*A.*) "Yes, it is more like that." Is that the passage you refer to?

(*Mr. Bidder.*) I do not know why my learned friend interrupted me, but that is not the same thing as he is saying now, although the two things are not inconsistent.

10,280. (*Chairman.*) I understand you to say in sea water the proportion of nitrogen to carbon is as 1 to 1.5?—Yes.

(*Mr. Bidder.*) Say two to three.

(*Witness.*) You will see that sometimes it is actually 1 to 1, and less than 1 to 1.

10,281. (*Mr. Bidder.*) You have put in Table No. 2, which summarises the results of all these analyses from Teddington to Purfleet, and indicates the increasing ratio of nitrogen to carbon as you go down the river? Yes, and then rises again at Erith, for there again Erith comes in, in an exceptional manner as it does over and over again.

10,282. Is it not the case that when you analysed the mud in the river you found an opposite result, that the ratio of the nitrogen to carbon ruled if anything less as you went down the river?—I have no doubt you are correct.

10,283. (*Mr. Bidder.*) I am now referring to a table which will be found on page 561 of Dr. Tidy's evidence upon the Mud Inquiry of 1880.

(*To the Witness.*) To make it clear to the Commission, those are muds I think?—Yes, those are muds.

10,284. And they range from a good way up above Teddington; they go up to Clewer and then they go down to Erith?—Yes.

10,285. The ratio of the nitrogen to carbon, you gave up in the whole region above Teddington as 1 to 5·2?—In the muds.

10,286. In the upper tidal reaches it drops from 1 to 10·4 to 1 to 1·77, which it is in the lower tidal reaches? Yes.

10,287. So that in the Mud Inquiry the result of many analyses was that the ratio of the nitrogen to carbon was less in what you charge as the polluted section of the river, than it was in the pure water above Teddington Weir?—That was so. I daresay you will remember we had a great deal to say about that, but I think it was capable of explanation.

10,288. It wanted a great deal of explanation because it was contrary to what you were insisting upon?—No, pardon me there.

10,289. I will turn to your evidence?—But read it all.

10,290. Do you deny that you said upon that occasion an increasing ratio of nitrogen to carbon was indicative of pollution?—No, but you will remember that there was something to be said about the high ratio of the nitrogen to carbon in the higher reaches.

10,291. I have no doubt you would have had something to say to it, now I referred a little time ago to the startling and anomalous variations of the free oxygen. I think I may, with equal confidence, refer to the same table as showing an equally violent variation in the ratio of the nitrogen to the carbon?—I think you may.

10,292. If the Commissioners will turn to Table No. 17. "Samples of Thames water taken at Erith," we shall see how, either from the admixture of sea water, or for some reason or other, the ratio of nitrogen to carbon varied at the same place at different times for instance, you give four observations upon the 28th of October, you give the organic carbon and you give the organic nitrogen in consecutive columns, now I do not know whether you can answer me, the first one gives a ratio of 1 to 4·5, that is at 10 o'clock?—Yes, it is so.

10,293. The one of an hour and a half later gives you 1 to 3·2?—Yes.

10,294. The one at four in the evening gives you 1 to 4·1?—Yes.

10,295. And the one at five o'clock gives you 1 to 2 within an hour at the same place?—I presume so, I did not take the samples.

10,296. Take another,—October the 30th, the one I referred to for another purpose, the low water one gives 1 to 3·5, and the other 1 to 5·2?—Yes.

10,297. Of course you would say that is what you would expect because it was sewage, now the next day gives you just the reverse, the low water one gives you 1 to 5·4, and the high water one gives you 1 to 3·6?—You cannot tell anything about the sewage because they let it in at all times.

10,298. But you cannot at high water at Erith get sewage because there is no mechanical arrangement by which we can send sewage down to Erith upon the flood?—I have seen it let out at dead low water.

10,299. But we cannot send it down to Erith against the tide, so you cannot suggest that we can increase the ratio of the nitrogen to carbon by letting out the sewage against the tide?—It might have gone out at low water and come back again.

*Dr. C. M. Tidy, M.A., M.B.*

27 Feb. 1883.

10,300. (*Lr. Stevenson.*) Are these samples taken at absolute high water and absolute low water, or at the higher and lower tides respectively?—I do not know.

10,301. (*Mr. Bidder.*) When I speak of high water I do so inferentially from the analysis itself. Now I have the Nautical Almanack; upon the 31st of October, it was high water in the afternoon at London Bridge at 5—1, therefore down there it would be about 4·30, so it would be as near high water as anything could be, so that there are two successive days, upon the one of which you get the ratio of nitrogen to carbon reduced from 1 to 3½ to 1 to 5 by the high water coming in at flood tide, and upon the next day exactly the opposite result is produced, the low water being 1 to 5½, and the high water being 1 to 3½?—That is so.

10,302. I suppose you cannot suggest any reason for it?—I cannot.

10,303. Then what value is there in a ratio which can fluctuate in that enormous proportion and fluctuate directly contrary to the direction in which your theory should make it fluctuate?—I cannot explain all the circumstances under which these fluctuations occur, it is utterly impossible to do that.

10,304. Surely you will admit that the last fluctuation is diametrically opposite to what your theory would require, will you not?—One never knows exactly what is the position of things with respect to the discharge of sewage, or when it is going out.

10,305. Am I to go over that again and point out that the tide was rising?—But perhaps some had gone out which was coming back again. I do not know how much of what has gone out is coming back again, and it is a very fair inference.

10,306. Having drawn your attention to that, I leave it there, the next thing I have to ask you about is this, I will come to the big table presently in detail, but you said that the result of Dr. Letheby's experiments, as recorded in the printed book of 1856, was to show in the old sewers 56 grains of matter in solution and 38·15 in suspension?—I did not take it out of that book. I took it absolutely from the results in the laboratory book.

10,307. Will you refer to this book, page 125 (*handing to the Witness the Report of Messrs. Bidder, Hawksley, and Bazalgette, of* 1857?—I am bound to say I never saw this book, because it is one of the things I have wanted to get hold of and been unable to do so.

10,308. Excuse me, because I have already cross-examined you upon it on one occasion. What I want you to look at is that Table No. 13, which you see brings out the total of 38·15 grains of suspended matter, the very figure you have given us—it is divided into "soluble constituents," and "suspended ditto"—the soluble are given as 55·74 upon the average, and the suspended at 38·15?—It does look so.

10,309. I am not right in saying that those are the very observations upon which your evidence was founded?—No, it looks so, but I took mine from the laboratory book itself.

10,310. From Dr. Letheby's book?—Yes.

10,311. Those are Dr. Letheby's Tables?—Yes.

10,312. (*Chairman.*) You were Dr. Letheby's assistant, I think at that time?—I was.

10,313. (*Mr. Bidder.*) Now, I will ask you this—have you noticed that there is one thing which makes that, I will not say an unfair, but an unreliable, deduction—that is to say, you have averaged together very large sewers and very small sewers; for instance, the Commissioners have before them the Fleet Sewer with an average flow of 1642 cubic feet a minute, and the London Bridge Sewer with a flow of 1396, and on the other hand there are included some small sewers with a flow as small as seven feet and even four feet a minute. Then again you will notice the sewers which are heavily charged, especially the one which as regards soluble constituents raises the average enormously, is a very minute one; viz., the Town Dock sewer, which has a flow of even less than five feet a minute?—Yes, but the sewerage system must consist of large and small pipes.

10,314. But I ask you, does it appear to you a fair way of getting at the constituents of London sewage to take big and little sewers, and to average them as being all consisting of sewage of a certain constituency?—It would not have been fair to have taken the system as consisting of all large sewers, or to have taken the system as consisting of all small—I think taking the average is a fair way to do it.

(*Chairman.*) How does this bear upon the present inquiry?

(*Mr. Bidder.*) You must ask Dr. Tidy; he introduced it.

(*Chairman.*) He did not put in this table in any way, did he?

(*Mr. Bidder.*) Dr. Tidy put in the results of that table.

(*Witness.*) It looks like it, but I am bound to say I had never seen this exact table in my life.

(*Mr. Bidder.*) If you will refer to question 9879, Dr. Tidy was asked this question. "Tell us first of "all, if you please, what amount of matter in solution "you find in the London sewage, what sewage you "are taking for this purpose." To that he says in the course of his answer: "I have looked up a very "large number of experiments which were made, and "inasmuch as I was engaged upon them myself during "the time I was engaged as assistant to Dr. Letheby, "I may refer to them. I have here the analysis of a "gallon of sewage taken from 10 of the large City "sewers, I cannot exactly give their names, but they "were 10 of the large City sewers; the average flow "at mid-day from which is marked as 349 gallons per "minute. It was during the time I was assisting "Dr. Letheby as medical officer of health to the "City that those were taken." Then he says: "Now, "taking mid-day sewage, there was an average of 94 "grains of solid matter per gallon, of which 56 grains "were in solution and 38·15 grains in suspension; "of that 94 grains 31 grains were organic, 15 grains "of that organic matter were in solution, and 16 grains "in suspension."

10,315. (*Chairman.*) You might have had, if not this table, at any rate the contents of this table present to your mind?—I have very little doubt that it was so, only I still say I have never seen this table before. I had before me a much larger body of facts bearing upon this question than this table shows; indeed I went so far as to say I did not know the sewers I was referring to.

10,316. (*Mr. Bidder to the witness.*) You did. Now I will put what I was trying to put in another way, which I am sure you will answer. You say the matter in solution is 55·74 grains?—I did not say that. I said the results which I had looked at gave that result.

10,317. The result you draw from the experiments?—From the experiments recorded in the laboratory book, from which evidently this table is constructed, but whether all the experiments were used or not, I do not know.

10,318. It would not have been the fact, would it, if you had thrown the sewers into one common sewer, that the united sewage would have had anything like that amount of suspended matter, because upon the average the strong sewers are the little ones, and the weak sewers the big ones; for example, if you take the Fleet, which has nearly half the total flow, you will find that that contains 44 grains of soluble constituents, whereas that little Tower Dock sewer, which has a flow of only four cubic feet a minute, has a soluble constituent of 890 grains.

(*Chairman.*) There is a footnote about the Tower Dock. You will see by that note that the Tower Dock sewer is excluded owing to the peculiar composition of the sewage.

10,319. (*Mr. Bidder.*) I beg pardon, I had not noticed that. (*To the witness.*) Now, passing to the suspended matter; you have taken in the Custom House west sewer, which is represented as having

78·49 grains of suspended matter; that only discharges 22 feet in a minute?—Yes.

10,320. The Custom House sewer, which only discharges 22 feet a minute, contains 78 grains of suspended matter, whereas the two big ones at the head of the list, which contain nearly nine-tenths of the whole sewage, contain only 29 and 22·44 respectively?—That is so; but seeing, as I said before, that you do not have the large sewers all at one place, and all the small ones at another, it seems fair, if you are going to take the average, that you should take large and small together.

10,321. It is not the result you would have arrived at if the water of all these sewers were poured into one sewer?—I am not so certain of that.

10,322. If there are 10 parts of one grain and one part of 30 grains, the average would not be 20?—But at the same time I do not know the length of the small sewers and the length of the large. Before I give you an average upon that basis, I must know the length of the small sewers and the length of the large, because the question is, what is the composition of the sewage when it reaches the outfall.

10,323. But you have given a certain result as from these experiments. I only put it to you that it is an incorrect result from these experiments?—I do not admit that it is not, but I would go further and say this: that it is a result which practically coincides with or is not very far off from the results obtained by the Rivers Pollution Commission.

10,324. (*Chairman.*) This is not the witness's table, to begin with, and therefore we do not quite understand the meaning of this table. You have here the Fleet sewer given as 1642 for the average flow per minute, and the soluble constituents 44 grains; is that per gallon?—Yes.

10,325. (*Dr. de Chaumont.*) In making up the average from the results which you had before you, did you take simply the arithmetical average?—Yes, I did.

10,326. You did not make any allowance for the quantity of sewage coming from each sewer?—I did not, upon the ground, which I say I believe is the correct one, that the sewage of London is made up out of large and small sewers; therefore I believe that is a fair way of doing it.

10,327. (*Mr. Bidder.*) Now I have it clearly, that when you gave those figures as the result of this experiment you took the simple arithmetical mean of the figures without any regard to the length or the size of the sewers?—Exactly.

10,328. Again, that was only the average of the mid-day sewage?—That was so.

10,329. And under no circumstances would it be representative of the average sewage of the 24 hours?—No, it would not represent night sewage, and it would not represent storm sewage; the night sewage would be very much less, and the storm sewage would be immensely greater, therefore I have taken that mid-day sewage as in some wise representative, that is to say, neither taking the very extreme of storm nor the very weak night sewage.

10,330. But storms are casual and seldom, but night is a thing which comes once in 24 hours?—But may I just say, my own experience is that the greater effects of storms infinitely over-balance the diluting effects of night.

10,331. I am coming to that, but at present, if you cast your eyes on that same book, back to the table before Table No. 12 in the Report——

10,332. (*Chairman.*) Your evidence in answer to Questions 9879 and 9880 was substantially based upon the information given in those tables?—It looked so, clearly; but, as I have said, I never saw those tables before.

10,333. (*Professor Williamson.*) And not merely the facts, but the facts used in the same way as they were used in by the compiler of the table?—Quite so. I am bound to tell you I only turned to the laboratory book.

10,334. (*Chairman.*) Upon looking at those tables and those averages, you would admit that they were not reliable?—I am afraid that there are no absolutely reliable results, unfortunately, and therefore we have to do the best we can. With regard to the whole question of what is the composition of sewage, changing as it does with every storm, and changing between night and day, the only way in which you could get an absolute result would be to take a certain quantity, say, every half-hour during a year. I wish to state very clearly that I do not put these forward as absolute results; they cannot be; no results can be, I am sorry to say.

10,335. (*Professor Williamson.*) Let me put this to you. You will understand that it is not a question of the validity or otherwise of the special observations here quoted, it is rather a question of the use to be made of them in taking what is called an average, that is to say, taking equal quantities of these various sewages from both large and small sewers, and arriving at a certain number of grains to a gallon as though they were supplying sewage in equal quantities; that is something very different from an average?—All the table does is to show that in a certain number of sewers a certain quantity of sewage has been collected, that sewage contains so much suspended and so much dissolved matter, and the totals are added up and divided by the number.

10,336. (*Mr. Bidder.*) But your 38·15 grains multiplied by the total quantity of sewage in these sewers would not represent the quantity that was in them?—No.

10,337. (*Professor Williamson.*) An equal number of samples would not represent an equal amount of sewage?—No.

10,338. (*Mr. Bidder.*) If you were to take the total number of gallons a minute and multiply it by your 38·15, you would not get the average quantity of suspended matter, or anything like it?—Certainly not.

10,339. Now Dr. Letheby gives in the previous table the result of his analysis of the night sewage?—He does.

10,340. In which we see the effect of the night in modifying the day sewage; and this is subject to the same observation, that he is using arithmetical averages; that which he made 38·15 by day comes to 13·99 by night?—That is so.

10,341. Now we pass from Dr. Letheby and his experiments to some others. Have you worked out, even accepting that figure of Dr. Letheby for night and day, what would be the average for the whole 24 hours?—I have not.

10,342. However, now to come to something more immediately relating to the present time; you told us you had yourself made observations relating to sewage at Barking and Crossness, and I understand your result is that the sewage delivered at Barking and Crossness contains an average of about 25 grains to the gallon?—Yes; that is to say, omitting storm sewage.

10,343. Shall we call it the normal sewage; will you find any fault with that?—No.

10,344. I think you have increased your estimate since I had the pleasure of examining you before upon this subject; you then put it at 22 grains?—I put it at from 23 to 25 grains, I think.

10,345. I think you made it 22. At question 6009 I asked you, "What is the total number of grains to "the gallon you have found during your observation "of the sewage. I think, if I understand right, it is "about 22 to 23 grains to the gallon," and your answer was, "I think that must be about it"?—I think I should rather have said 23 to 25, but still it does not much matter.

10,346. Now, I understand you to say that the increase during the time of heavy rain and storm in your judgment raises that; of course we know it must raise it, but raises it until it is equal to 44 or 45 grains; what is your ground for that statement?—My first ground for that is the experiment of Dr. Frankland. In the report of the Rivers Pollution

*Dr. C. M. Tidy, M.A., M.B.*
27 Feb. 1883.

Commission, page 29, Dr. Frankland gives a series of analyses, and although I am quite aware that you may take objection to one or two of the high numbers, nevertheless, it gives an average of between 45 and 50 grains. Then, secondly, during a storm our own experiments gave some very high numbers, which numbers in the main (there was a little discrepancy, owning, no doubt, to the different times in which we obtained the sample or the different condition in which we obtained the sample) were agreed to by Mr. Keats. And I would just say that Dr. Frankland and myself, upon the 30th of December, if you look at the answer to Question 6227 upon the Mud Inquiry, found 119 grains of suspended matter in a gallon, whilst Mr. Keats admitted that he found even 95 grains. No doubt there was a litte difference in our sample.

10,347. I think you must be referring to Question No. 6256. I think I put it to you that you or Dr. Frankland found 119 grains in the samples in the Fleet sewer, and we could only find 95?—No, excuse me, the 119 grains was not found in the Fleet sewer, it was found in the Northern Outfall.

10,348. You are right?—So that in the sample which was practically agreed to by the Metropolitan Board of Works we found 119 grains of suspended matter.

10,349. (*Professor Williamson.*) Was that in a period of storm?—Yes; but the point I am trying to make clear at the moment is that, though I admit 25 grains to be the normal amount of suspended matter in a gallon, yet the time when we get storm sewage is when we bring up the average enormously by the increase of suspended matter.

10,350. (*Mr. Bidder.*) You have no record, have you, of the duration of that 119 grains flow?—No.

10,351. You know it is very short, do you not?—I am quite aware of the facts that were brought forward, but at the same time I only say that such was found.

10,352. It is something more than a detail, is it not; it is a fact, is it not, that, taking that one occasion, the 119 grains flow only prevailed for an hour or so, and within a very short time had dropped down to the normal?—I do not think you are justified in saying "an hour or so," I know exactly the experiment you are referring to, and I must say I do not think you are justified in saying "an hour or so."

10,353. If you will look at page 975. Question 10,164, Mr. Keats was examined, and the question was put by the umpire: "There seems to have been "also a quarter of an inch on the 31st," and his answer was, "That is the point: I want to direct "your attention to that. On the 30th a quarter "of an inch of rain fell and brought down 95 grains "of solid matter in the sewage. But then on the "31st there was again a quarter of an inch of rain, "but it brought down no extraordinary quantity of "matter to the outfall"?—No, because the first storm had washed it out. Now I venture to refer to the circumstance you have just referred to. I would ask you to refer to Question 9980 on page 954. You will find that it was in the 24 hours after that it fell to 28·2, and not within an hour.

10,354. I did not say it fell to 28, but I said that it fell within 24 hours to the normal?—No, I beg your pardon, you said it fell within an hour or two to the normal. Now the next fall to 20·62 grains per gallon was after 48 hours. It is not a question of hour by hour; it is a question of day by day.

10,355. That is to say, there having come a storm which washed out the gutters and swept out the refuse it fell in 24 hours to 28, and in the second 24 hours, it fell to far below its normal?—Manifestly that must be the case, because the whole theory of storm sewage is that a large quantity of material collects in the pipes, and then a storm comes and washes it out, and then it must fall below the normal; then it collects again—another storm comes and washes it out.

10,356. That observation you have drawn my attention to, shows that there was a temporary rise to about 100 grains, and that is succeeded by a rapid fall, so that within 48 hours the sewage has fallen below its normal?—Quite so.

10,357. That being so, have you any observation from which you can deduce that the excess in this time of heavy rainfall more or appreciably more than balances the subsequent defect?—No, and I know of none that can absolutely prove it, except that I am quite sure that to take 24 or 25 grains a gallon, does not give a fair result.

10,358. So that when you said last week you put it between 40 and 45, you had no basis for that statement?—I did not state it as between 40 and 45, I gave a much broader number, because I know the extreme difficulty of giving such opinions.

(*Chairman.*) At Question 9983 you said "I take it "that as the normal quantity from 23 to 25 grains "may fairly be put down, but taking all the rest of "the year I doubt if it would come out at less than "from 45 to 50.'" Then I appear to have asked you, "That would include the storm sewage?" To which you replied, "Yes. In the report of the Rivers "Pollution Commission we have a sample containing "164 grains per gallon, and I have myself found "more than that, so I do not think we are taking "an excessive quantity."

10,359. (*Mr. Bidder.*) Now let me dispose of Mr. Keats's report to the Rivers Pollution Commission as affecting this matter. What is the date of that report?—1870.

10,360. What is the date of the observation?—February, March, and April, 1869.

10,361. You have referred in confirmation of your view to the first report of the Rivers Pollution Commission, and to the tables upon page 29, which are all based upon observations in the years 1867, 1868, and 1869, is that so?—No; I am only taking the results of observations taken on February the 23rd, 1869.

10,362. Taking 1869 only, then, are you not aware that these observations were made before the general introduction of catch pits for the purpose of intercepting the road drift?—No, I am not indeed.

10,363. One can readily understand if that is so, that the introduction of catch pits throughout London generally for the purpose of intercepting the road drift, would make a material difference in the amount of suspended matter in that sewage?—I do not admit anything of the kind.

10,364. You do not admit that the introduction of catch pits would make any difference in the amount of suspended matter in the overflow?—I do not say that it would make no difference, but that it would not completely alter the matter. But that is not the only high number I can give. I would like to draw attention to Question 6240 in the Mud Inquiry (that was Dr. Frankland's evidence, but I think I may take the responsibility of it at the same time), where it is stated that from the Fleet Sewer's storm outfall we obtained 447 grains of suspended matter.

10,365. You did, and do you recollect what happened—do you recollect we insisted upon having the man who took the sample, and that it turned out that he had been scraping up the mud with a tin can—scraping a hole in the mud?—I do not remember that; I do not admit that; I do not believe myself that the 116 grains per gallon is anything like the quantity that comes down in the storm sewage.

10,366. I think we may now pass to your big table, because I have some questions in detail to ask you upon it, and alongside of your big table, we may take the next Table, No. 2, which is a condensed summary of the results which you consider material in Table No. 1, or at least of some of the results; I want to ask you this first with regard to that table: there is no doubt, is there, that the condition of the river as regards free oxygen, nitrogen and carbon, ratio, and various other things very much depends upon the time of the tide?—I do not know how much it does.

10,367. But it must more or less?—To a certain extent.

10,368. You would expect it to, would you not?—It may.

10,369. You have divided this table in your summary into five sections?—Yes.

10,370. In which you show the progressive diminution of free oxygen, and with the exception of the last, an increase in the ratio of the nitrogen to carbon. Is it not the fact that in four of those sections, 1, 2, 3, and 5, all the observations were taken at low water, whereas in the 4th section, which is in the middle, the observation was taken at high water, the amount of chlorine will show it you by itself?—Section No. 1 is taken about $1\frac{1}{4}$ hours before high water.

10,371. I do not mean upon the actual turn of the tide?—I should like to go through them all, first to see how far they are correct, because I do not think they are altogether. I have every one marked, and I think it might be worth while doing so. No. 1 was taken at 1 hour 15 minutes before high water.

10,372. That is at Teddington?—Yes. No. 2 was taken at three hours after high water. I have considered every one of these points, and I think it right to mention that before I gave in this table, I distinctly stated that it was so, that I had taken cognizance of the fact.

10,373. Perhaps I may be wrong as to the top ones, but begin at the other end; take your 5th section where the tide is of importance?—I would say that No. 54 was taken $3\frac{3}{4}$ hours before high water. 55 and 56 were taken 2 hours and 30 minutes before high water, and so on. I do not think that will assist you much, because I do not believe that Erith will assist you much in the case.

10,374. All those are taken nearer low water than high water, are they not?—For instance, No. 58, the last one that I took was 3 hours and 50 minutes before high water.

30,375. That is nearer low water than high, is it not?—It is.

10,376. When I come to the next section, from 43 to 53, those are all nearer low water than high water?—They are a little.

10,377. You have only given the time of one of them, but I will tell you why I put the question to you because I look at the quantity of chlorine?—You are quite right in that respect, but at the same time, I do not think you are absolutely right, though I cannot give you the time.

10,378. I will take it that I am substantially right? My own impression now I think of it is, that you are wrong.

10,379. If you look at the table it is a very startling thing. Now, in the next section above, from No. 36 to 42, the samples are all apparently taken near high water, because the chlorine is greater than in the section below?—Yes, I quite admit that circumstance.

10,380. If I am right in that, and that is what I wish to suggest to you, that your third section is taken nearer high water, and all the rest nearer low water, it very much vitiates the result drawn from a comparison of the various sections, does it not?—It gives you a general idea. Comparing the amount of chlorine, the free oxygen, and the ratio of the nitrogen to carbon, it shows that there is no such vast difference as you would suggest.

10,381. Take the third section and let us see if there is no great difference between Greenwich and the Albert Dock and the first section. We have at Woolwich, 327·4 of chlorine, at Charlton, 307·8, at Charlton Ballast Wharf, 303·8, at Clyde Wharf, 292·0, at West India Dock, 256, at Greenwich Royal Naval College, 225, that is the top of the section, then we rise to the next section, Deptford, 37, Millwall, 25, off Sewards, 17, at the Tunnel Pier, 9, in a line with the Monument, 2·8, that is at London Bridge, and so on?—I mentioned before I put in the table that the samples were taken at different states of the tide.

10,382. How can you suggest to the Commission, that they can with any confidence, draw any comparison between the amount of free oxygen and of chlorine and salt, and so on, from samples so taken?—I think I mentioned that the proper way to take the samples was an impracticable way, viz., to have a series of people along the river taking them at the same time.

10,383. But how does it happen that we get some of them taken at high water, and some at low water?—I think I can explain that by saying, that I took them on different days.

10,384. Let me draw attention to another inaccuracy; if you look at Table 2, you will see the amount of free oxygen per gallon in cubic inches, and having got that down to ·8 you represent that in the fourth section as ·717, as being the average of the observations from 43 to 53. What you say is "Beckton to Crossness 43 to 53 free oxygen ·717"?—It ought to be.

10,385. Now there is a more serious mistake, one of these numbers, No. 44, is a sample of sewage from Beckton, now is it a fair thing, as a sample of the River Thames, to give an actual sample of the sewage?—It is not, and I should not have put it in, if it had struck me, but I think it will make very little difference.

10,386. It does indeed. Now I will draw your attention to another, No. 43 is as bad or rather worse, and is taken from the immediate neighbourhood of the Beckton sewer?—But that is a part of the River Thames.

10,387. But that is a water which is immediately affected by the locality of that sewer. Now would you be surprised to hear that if you only correct the amount of free oxygen by taking out the Beckton sewage, that will show us a better figure than in the reach above. I will leave that to you to answer to-morrow. Now I will mention another thing, this table of yours shows another very singular thing does it not; and that is, that there is a remarkable polluted section which we have nothing to do with. If you look at Nos. 29 to 35, which embraces that part of the river from Blackfriars Bridge to Deptford, if we look at the matter in suspension, especially the organic matter, we shall see, that whereas above Blackfriars Bridge the total matter had ranged from two to eight and nine grains per gallon, yet that particular section, in a most startling manner, shows 18, 15, 15, and 19 grains per gallon?—Yes; they were taken on different days.

10,388. That shows that it was not peculiar to one particular day?—Let me point out that in that polluted section which you are referring to, the samples were taken entirely upon June the 21st, and that high rate of matter in suspension seems to be peculiar to that date in some way or other.

10,389. Is it so, because upon the 21st of June, whereas at Blackfriars Bridge you find 15 grains, upon the same day at Lambeth Bridge you find only eight?—There is a difference, but still all these samples in this polluted section were taken upon the 21st of June.

10,390. One is taken upon the 11th of July?—You are quite correct.

10,391. Now is not that very strong evidence rather of a source of pollution operating upon that section,—whether it be drains or docks, or whatever it may be,—which is quite independent of the Metropolitan Board of Works outfall?—Will you allow me to refer to the table? I notice that, taking the percentages of organic matter in that series which you are referring to.

10,392. That they are very high?—There are two numbers high, two moderate, and the rest fairly normal.

10,393. You mean to say that though the quantity of grains is more, you do not think the quantity of organic matter is more?—There is something else I want to note, and that is that so far as the organic carbon is concerned, it is not very high certainly.

10,394. Let me follow that up; you put it to me that though the quantity of suspended matter has increased very remarkably, it does not follow that the organic matter has; now I ask you to refer and you

*Dr. C. M. Tidy, M.A., M.B.*

27 Feb. 1883.

will see that the organic matter, according to your own showing, is three times as much in that section as it is generally in the river?—Pardon me.

10,395. Take first, for instance, Blackfriars Bridge, No. 29; there are 15 grains there?—Of what?

10,396. Of suspended matter, of which 18·50 per cent. is organic matter?—Whereas I draw your attention to this, that at Westminster Bridge, No. 28, there were only 7 grains of matter in suspension, of which also 18 per cent. was organic matter.

10,397. I am giving you the whole section; if you take Blackfriars Bridge there are 15 grains and 18·50 per cent. (I will not take the trouble to work them out, you can work them out by to-morrow morning) that is 2·8 grains of organic matter?—That is so.

10,398. Now the next, No. 30, is 4·9 grains of organic matter; No. 31 is 2·8; No. 32 is 6·8; No. 33 5·2; No. 34, 4·5; and No. 35 is 2·5. The average of those you will find is 4·2 grains of organic matter, whereas if you take a general line of the others above and below, it ranges about 1·5. Now, if those figures are right, can you explain how in the reach from Blackfriars Bridge to Deptford you find not merely an increase of the organic matter, but really a trebling of the quantity of organic matter?—I am not able to account at the moment for the reasons, there may be engineering reasons for it.

10,399. (*Mr. Lumley Smith.*) There is a storm overflow coming in at Blackfriars, is there not?—I think that might account for it very likely.

10,400. (*Mr. Bidder.*) But when we were discussing the evidence of gentlemen from Deptford, we found bad smells when crossing in the steamer from Greenwich. Is it not a remarkable fact, that we find treble the organic matter there that we find in the neighbourhood of the outfalls?—I would say that that which renders the water emphatically the most impure, is that which is present in the form of soluble matter.

10,401. That is not the thing which the people smell in the steamboats if they do smell anything?—There is no doubt about there being something to smell, but I say you must not judge of the purity or impurity of the water by the amount of suspended matter.

10,402. How do you account for the remarkable or comparative absence of free oxygen in the section from Putney to Vauxhall?—I do not know.

10,403. It is very remarkable, is it not?—It is. There is organic matter going into the river and we know there is a constant contest going on between the organic matter and the oxygen. Sometimes the oxygen has too much work to do, and sometimes it is just balanced, and we get those variations in that way.

10,404. You agreed with me that to some extent the condition of the tide would affect the results shown here. Just let me, as some index of that, as one element, draw your attention to this: the lowest section, the Erith section, will show you as an average about ·5 of a cubic inch of oxygen?—That is right.

10,405. Your large table ranging over a considerable period at Erith shows under different circumstances oxygen to more than treble that quantity?—It is so undoubtedly, that is to say, that if the sea-water gets up there, in which the oxygen has not been called upon to do a great amount of work, then you get the oxygen in a much larger quantity. I do not give that as an absolute explanation of the discrepancy.

10,406. I am now upon this question: how far the result of these tables taken upon one day, the 6th of July, can be taken as an indication of the general state of the river; your result from this day is ·5 of oxygen, whereas your result over a long period of observations extending over a fortnight shows that ·5 is quite exceptional?—I have stated that it was difficult to draw conclusions about Erith.

10,407. But I have pointed out that your ·5 is a very exceptional and unusual condition?—I do not admit that.

10,408. I venture to say that the average amount of oxygen in Erith is about 1·2; should I be wrong in saying that?—I dare say not, which means perhaps that a very large quantity of sea water has come in, and that the call upon the oxygen of that sea water has not been such as to get rid of it.

10,409. You gave the Commission some evidence with regard to the constitution of the sewage itself, you emphasised the number of tons of dry excrementitious matter in suspension, and in solution?—Yes.

10,410. And I believe, if I understood you correctly, those results were based upon certain German observations?—Not entirely. I gave you Messrs. Röder and Eickhorn's observations upon urine.

10,411. Here again the figures are so startlingly identical, that I cannot help thinking (you will tell me if I am wrong) that I have identified your authority and theirs, and that they are both taken from a common source of observation, they take it from Woolff and Lehmann, do they not?—(*After referring to a book.*) They do. I just want to say that I have taken the urine from Röder and Eickhorn because I have no doubt that is about correct, but there have been a good many researches as to the quantity of fæcal matter that should be taken per head; therefore I have not altogether taken Messrs. Röder and Eickhorn's numbers.

10,412. Will you just refer to that report (*handing a book to the witness*) and see if I have not tapped your source of information: look at the number of men, women, boys, and girls out of the 100,000?—That is right enough.

10,413. I think if you look there and follow it out, that somehow or other you have some mistakes in your arithmetic, and that you have brought out results which, although you employed them, were somewhat exaggerated. In the first place as regards the fæcal matter they give a result of less than yours?—I would just say I have not taken Messrs. Röder and Eickhorn's calculations as regards fæcal matter, I will say at once that there have been other observations taken since then upon an English population, and I should say, perhaps, by one who knows a great deal about it, and one whose views are very clear upon the subject, that is Professor Way. He takes what I think is really a very fair estimate, namely, about 1,750 grains as the quantity in England of fœcal matter passed per head, including men, women, boys, and girls to the number stated by Messrs. Röder and Eickborn.

10,414. But do not throw over your authority so entirely, directly I have found out where it is?—But I told you where it was. There was no attempt on my part to conceal where I got it from.

10,415. Will you kindly tell me whether, if you adopt the figures given by your authority as to the result from 100,000 people, that does not give a very different result?—I will tell you what I make it.

10,416. Will you tell me if I am not right in taking the fæcal matter for the whole of London at 90 tons per day?—It would be 94 tons.

10,417. And the dry soluble matter if dried, would be about 185 tons?—No, I do not think you are quite justified in saying that. I would just say that the quantity I have taken as the solid matter in the urine, I have taken from Professor Kirke's book.

10,418. I would like to have it from the same authority as you relied upon previously?—I have not relied absolutely upon the other.

(*Chairman.*) I see Messrs. Woolff and Lehmann's Book is dated 1880. What was the date of Messrs. Röder and Eickhorn's work; was it a book published before 1880?

(*Mr. Michael.*) It is the same thing, one is quoted from the other.

10,419. (*Mr. Bidder.*) Mr. Röder quotes from Messrs. Woolff and Lehmann. Messrs. Woolff and Lehmann are the original authorities. (*To the witness.*) I think you will find you have taken the fæces twice over?—I wish to put it quite clearly.

10,420. You gave 100 tons as the insoluble?—

I gave 111·6 tons as the total, and of that 100·5 tons insoluble and 11·1 tons soluble. Then I took 2½ ozs. a day as the solid dry matter of urine; that calculated out, comes to 282·3 tons. 282·3 tons added to 111·6 tons is 393·9 tons, and I said 400.

10,421. I beg your pardon; you said something a good deal more than 400, you said 444?—It is 444 tons of moist fæcal matter, because I am taking the fœcal matter as containing 75 per cent. of moisture; therefore it is 444 tons of fœcal matter.

10,422. I think I misunderstood you. You will find in your 2½ ozs. of solid derivable from the urine, that you have taken the wrong figure, and that that is the figure which includes the fæcal matter?—No, that is not so. I have taken a great deal of trouble about the matter, and I am prepared upon it at all points.

10,423. Will you take Messrs. Woolff and Lehmann's book. If you refer to that book, you will find that for 4,000,000 of people the quantity of fæcal matter is 185 tons a day?—May I tell you my authority upon this—it is Professor Parkes. Professor Parkes states that daily 1106·9 grains of solid matter are passed in the urine per head of the population; 1106·9 grains is 2·53 ozs.; 2·53 multiplied by 4,000,000 will give you the result I have stated.

10,424. I think that must be taking adults, and I will tell you why. I have given you your rope, now let me have a little rope. If you take the results of Messrs. Woolff and Lehmann in that book from which you get your solid——— ?—No, I beg your pardon I did not take it from there.

*Dr. C. M. Tidy, M.A., M.B.*

27 Feb. 1883.

10,425. At all events you will see they give a certain amount of solid matter from the urine for the 100,000 population?—German.

10,426. One twenty-fifth of that, he says, is solid residuum?—It would come out a little different.

10,427. Not very different, it does not indeed——? —If you divide that by 25 and multiply it by 40.

10,428. (*Chairman.*) Are these figures identical with Messrs. Röder and Eickhorn's?—Yes, they seem to be so. I do not think it will make any vast amount of difference.

(*Mr. Bidder.*) But I do not say that because I have tried it, and I know it does.

(*Chairman.*) If the figures are identical one can work out the sum at once.

(*Mr. Bidder.*) He does not know it and I do. I put it at the time: do they not make 185 tons instead of 283—now I will leave that question. I will not ask you to worry yourself by answering it now.

Adjourned to to-morrow at half-past 12 o'clock.

---

# TWENTY-SIXTH DAY.

## Wednesday 28th February, 1883.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

| | |
|---|---|
| COLONEL C. B. EWART, C.B., R.E. | THOMAS STEVENSON, Esq., M.D. |
| PROFESSOR WILLIAMSON, F.R.S. | JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E. |
| FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S. | WILLIAM POLE, Esq., F.R.S., *Secretary.* |

DR. CHARLES MEYMOTT TIDY, M.A., M.B., further cross-examined.

10,429. (*Mr. Bidder.*) Just let us take up one or two loose ends that we left last night. In the first place you were going to look into that question of the calculation of the amount of dry excrementitious matter, and I have no doubt you have done it?—I have, and I may say that German weights are not English weights, a German lb. is not an English lb. I will give you certain differences that may be worth noting; the Prussian lb. is 1·0311 lbs. avoirdupois; the English lb. is ·9698 Prussian lb., one German zoll lb. is 1·1023 English lbs., and the English lb. is ·90719 German zoll lb.

10,430. The quantities in this book I refer to, are not given in lbs. at all?—They are not.

10,431. They are given in tons or 1000 kilos, which I think is within 1 per cent. of our ton?—I am bound to say having thought the matter over as fully as I can, that although taking Messrs. Röder and Eickhorn's calculations as Germans, there is a certain difference: yet let me say that only brings it down to, I think I am right in saying, 97 tons; it is the difference between 97 and 111 tons.

10,432. What is the other difference?—The other is a greater difference.

10,433. Your 97 is very nearly in accordance with the figure that we ourselves made it?—Therefore, as far as that is concerned, if you like to take it in that way, instead of putting it as 444 tons of moist fæces, it is about 385 tons.

10,434. We are agreed substantially, that the amount of dry matter from the fæces is somewhere about 97 tons; now, I want to go to the other matter, the dry matter in solution?—But, I contend that you did ask me about the quantity of the fæces.

28 Feb. 1883.

10,435. (*Chairman.*) Instead of 111 it will be 97?—Yes; and then again in order to get the moist fæces, which is the actual fæcal matter thrown into the Thames, you multiply that 97 by 4 which brings it to about 385 tons of moist fæces per day, which is Mr. Bidder's own number.

10,436. (*Mr. Bidder.*) I am not asking a word about that; but now coming to the other matter I am asking about, have you corrected the 283 which represents solid matter in solution?—I have.

10,437. What do you make it?—According to that calculation, it is about 197 tons instead of 282.

10,438. That is a little more than I make, but I do not quarrel with it?—But let me say this, that I do not accept it.

10,439. (*Dr. Stevenson.*) Now, I will ask you what amount of dry urine you take per head per diem; you said 2½ ounces; do you adhere to that?—Yes; 1,100 grains is a very fair average for men, women, and children, of which I take about 512 as urea, and the rest as extractors, that is to say, it is 2½ ounces of dry matter from the urine, and one ounce of dry matter from the fæces, and I believe that is very nearly the fact.

10,440. (*Mr. Bidder.*) There is another authority I dare say you are acquainted with. I think you mentioned Dr. Parkes. If you look to page 131 of his work, you will find that he gives 40 ozs. of urine per head?—I think that is a very small amount. I

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

really think 40 ozs. a low calculation for the quantity of urine per head.

10,441. (*Dr. de Chaumont.*) How many ounces do you take?—I make out, that taking adults, male and female, 60 oz. is about the quantity as near as possible. I am aware that most modern books give 50 oz.

10,442. But we are dealing now with a mixed population, both adults and children?—Then I think 40 oz. is a very fair number.

10,443. (*Chairman.*) What would you say, taking units of the population?—Taking units of the population, I think that 40 oz. is a fair number.

10,444. (*Dr. Stevenson.*) In answer to Question 9,907, have you not taken very nearly 40 oz. as the basis of your calculation?—Yes, I have. I have taken the population calculated upon Messrs. Röder and Eickhorn's views, that is to say, a population of 100,000 contains so many men, women, and children, from which I get the figure I have given.

10,445. (*Colonel Ewart.*) Have you thought over the question of the time required for putrefaction?—Yes, but I should not like to give you an answer at once. It is a difficult question to answer; it is more difficult to answer than would occur at first sight.

10,446. (*Mr. Bidder.*) I think there is one point in which all the authorities agree, that the proportion of urinal matter that you get dry is 4 per cent.—that is what Messrs. Woolff and Lehmann say,—one twenty-fifth?—I think that seems somewhere about it. I am not sure that I can give it you exactly.

10,447. I think you were mistaken just now in telling Dr. Stevenson that you had taken 40 oz. in your previous calculations, because, if you will take 4 per cent. of 40 oz., that gives you 1·6 oz. of dry matter, but you told the Commission that it was $2\frac{1}{2}$ oz.

10,448. (*Dr. de Chaumont.*) But did you take 4 per cent.?—I did not. I said that off-hand I could not say. (*To Mr. Bidder.*) I do not accept your number.

10,449. (*Mr. Bidder.*) But just let us get the figures right, and then we may arrive at it?—But I am not accepting the 4 per cent.

10,450. But you agree to the 4 per cent., surely?—I do not indeed.

(*Chairman.*) One of my brother Commissioners, who has a knowledge of this subject, tells me that one of the authorities gives 4 per cent., another gives $4\frac{7}{10}$ths, and another gives as much as $6\frac{7}{10}$ths per cent.

10,451. (*Mr. Bidder.*) I think I am right in saying that Messrs. Woolff and Lehmann say 4 per cent., and I see that Dr. Burdon Sanderson, who is an authority upon this subject, says also 4 per cent.?—I think that 4 per cent. is too low, decidedly.

10,452. (*Chairman.*) There appear to be various authorities, some saying 4 per cent., some $4\frac{7}{10}$ths, and some $6\frac{7}{10}$ths per cent., and I believe Dr. Tidy takes the highest figure?—No, I do not at present; still I agree that the matter requires a good deal of consideration.

10,453. (*Mr. Bidder.*) At all events, you will agree with me, that if 4 per cent. is right and 40 oz. are taken, then your $2\frac{1}{2}$ oz. becomes $1\frac{1}{2}$?—Of course, the whole thing is a matter of calculation. I still think that mine is very nearly the right figure.

10,454. I put some figures upon your Table No. 1, and I hope you will accept them from me for the present, and afterwards you will be able to check them if I am wrong, about the increase of organic matter in a certain part of the river. First, I would ask if you have checked those figures?—I have not checked them.

10,455. Now, I want you to go to another matter. The quantity of fœcal dry matter being as much as you say, and the quantity of sewage being, as we know, or practically we may say, 26,000,000 cubic feet per diem put into the river, have you considered the extent of the dilution which that undergoes?—No, I have not.

10,456. Are you aware that it is about $\frac{1}{240}$th of the volume of water into which it is thrown?—I have not calculated it.

10,457. But is not that an important question?—I do not think it is; it is the addition of sewage to sewage; it is not the addition of sewage to fresh water; if it were the addition of sewage to fresh water, it would be important, but it is not that.

10,458. (*Chairman.*) You have not calculated it?—I have not.

10,459. (*Mr. Bidder.*) Assuming Mr. Mansergh's figure to be correct, will not that tell you what is the amount of dilution?—I have not been into that at all.

10,460. I wish you to go into it now?

(*Chairman.*) I think that to ask the witness in cross-examination to deduce general principles from the calculations which have been made by another witness, is rather carrying cross-examination too far.

(*Mr. Bidder.*) I ask the witness a particular question; to look at the volume of water into which the sewage of the river is discharged as calculated by Mr. Mansergh, and to tell us the amount of dilution it undergoes.

(*Witness.*) It is a calculation that you will do very much more rapidly than I can, and I will accept your figure.

10,461. I give you that figure subject to your checking it?—I will accept it for the purpose of the question.

10,462. I will give the figures to you so that I shall not trouble you. I will take September 14th, at high water. You see that the first column of that table of Mr. Mansergh's gives the content of the river at high water at certain sections; now you are aware that the sewage is, subject to the exceptions which have been referred to, poured in at the ebb tide?—It may be. I saw it going in at low water.

10,463. I said, "subject to certain exceptions"?—I was down there at low water and saw it going in, and I dare say it goes in every day.

10,464. The amount of water which goes past upon the ebb and upon the flow of the tide, is about 30 miles?

10,464A. (*Chairman.*) Do you know that?—I do not know anything at all about it.

10,465. (*Mr. Bidder.*) Will you accept it from me?—I do not know anything at all about it.

(*Chairman.*) You are furnishing the witness with a problem of which he has no personal knowledge whatever.

10,466. (*Mr. Bidder.*) He was here when the figures were put in. Mr. Baldwin Latham showed that the flow and ebb of the tide was about 30 miles. Now taking from Crossness, 13 miles above it, taking two sections above Crossness and a portion of another section, you find you have over 3,000,000,000 cubic feet to flow out with the tide; do you follow me?—I do not, indeed.

10,467. Assume from me that that is so, that shows a dilution of $\frac{1}{240}$th part?—A dilution of sewage with a little weaker sewage; yes.

10,468. You may call it a little weaker sewage if you please, but assume the sewage is put into something like 240 times its volume of river water?—Certainly, I can not.

10,469. (*Chairman.*) You are requested to assume that?—I will assume it, but I do not admit it.

10,470. (*Mr. Bidder.*) I do not want to catch you in a trap. I only give you the way the figures are arrived at, and I do not wish you to vouch for the accuracy of the calculation. Assume that the sewage is discharged into that volume of water?—No, that I do not admit.

10,471. Say a volume of liquid, at any rate?—Say sewage water, if you please.

10,472. I will call it liquid, 240 times its own volume; therefore it follows that your suspended matter in the sewage comes to a tenth of a grain per gallon in the river?—I do not know that.

10,473. If you have 25 grains in a gallon originally, and you put it into 240 gallons of water, it comes to

one tenth of a grain per gallon practically?—Yes, that I accept.

10,474. Have you also examined what your organic carbon and nitrogen in the sewage are with the view of ascertaining what portion of that which you find in the river is accounted for by the sewage?—No, I have made no calculation of the amount or percentage of the sewage in the river at all upon any occasion.

10,475. Was it not worth while to try?—No, it was not.

(*Chairman.*) This gentleman is a chemist, you know.

(*Mr. Bidder.*) And I am asking him a chemical question. If you mean to suggest that chemists are incapable of making the simplest calculations, I must protest against it. I know many chemists who are very clever arithmeticians, and I know that Dr. Tidy is not an exception to the rule. No man can be a successful chemist unless he is a good arithmetician.

(*Witness.*) Then I say at once I have made no such calculations; and I would prefer to make that clear, as I know that other questions would be asked upon it.

(*Chairman.*) We understand you to be here to give certain chemical evidence to the Commission.

(*Mr. Bidder.*) We suppose Dr. Tidy to be here to give valuable evidence to the Commissioners.

(*Witness.*) If it had been a question of the admixture of sewage with river water, I should have been competent to deal with it; if it had been a question of the admixture of sewage with sea water, I should again have been competent, perhaps, to have formed an opinion as to quantity; but when I have certain unknown factors with unknown quantities of three things, I do not feel myself, with those facts, at liberty to make any estimation of the quantities of sewage in the mixture; and, therefore, in questions of that nature, I gave my results, and others gave their results to the engineers to supply by sectional areas, which we had not, and which we were incapable of dealing with, details which I did not feel myself prepared to discuss.

10,476. But you have had the assistance of engineers upon your side, and have been in the room while they have been giving evidence. Do I correctly understand that you have not thought it worth while to make use of the figures which have been supplied to you as to the volume of the river so as to form any judgment as to what is the extent of dilution, and how far the outfalls of the Metropolitan Board of Works account for the defilement of the river?—I did not consider it my duty to do it.

10,477. (*Chairman.*) You did not consider it to be your duty?—If I had considered it my duty, I should have done it.

10,478. (*Mr. Bidder.*) Was it no part of your business as a chemist to have done it?—As a matter of fact, I have not done it. There were other matters to be taken into consideration, sectional areas and such like, which were not within my province.

10,479. (*Chairman.*) There must be some check to this cross-examination. You are cross-examining a chemist, and are going into the province of an engineer. You are, I think, therefore departing from the province of an expert chemist, and are examining upon questions of engineering.

(*Mr. Bidder.*) I am very sorry I have not made my question intelligible to you or to the witness, and I take the blame to myself. I am examining Dr. Tidy, not upon any question of engineering, but I am examining him entirely upon a chemical question. The question upon which I am cross-examining Dr. Tidy is this: Whether, having regard to the chemical facts upon which he has been dilating, and the results at which he has arrived, he has taken the trouble to compare the volume of water with the mass of materials which comes from the sewers, so as to be able to tell the Commission whether he believes the sewers are or are not the cause of these chemical phenomena.

(*Chairman.*) He says he has not.

10,480. (*Mr. Bidder to the witness.*) You are not prepared to say whether they are or not?—No, I do not know anything at all about it.

10,481. Now let me ask you this, and we will take care to keep very strictly within your province; you have described to the Commission a large quantity, so many hundred tons, of organic matter which goes into the river; I ask you, as a chemist, what becomes of that?—I have given a certain account of what becomes of it. I have said that, as regards, first of all, the insoluble matter, it floats about.

10,482. (*Chairman.*) This has all been given before?—I have dealt with all this. Some of it, I said, combines with aluminous compounds; it decomposes.

(*Chairman.*) You have given that answer, and need not give it again.

10,483. (*Mr. Bidder.*) You divided the sewage, I think, at any rate, you did upon another occasion, into that which continues to float about in the water (or, perhaps, "floating" is a word which does not cover it all, either floating, suspended, or carried in solution) and that which sinks to the bottom. One may divide it fairly that way. All the polluting elements of sewage must either in the run of the river sink to the bottom or else they must remain in the river as matter in suspension or matter in solution or dissipate into gas?—That is quite so.

10,484. Now, excluding for a moment that which sinks, if there is any, and which becomes part of the mud of the river, and confining the question to the other, in your belief is it not entirely consumed, that is to say, burnt up?—Eventually. Excluding the part that goes down to the bottom, the rest is oxidised.

10,485. And you would say absolutely annihilated?—Finally disappears. "Oxidised" means burnt up.

10,486. (*Mr. Abernethy.*) But if it is repeated day by day, does it disappear?—There is a good deal more to come out of this. That is just the point.

10,487. (*Mr. Bidder.*) You say "eventually." I put it to you, within a comparatively short time?—I am not going to admit that, unless you give me the precise conditions under which the admixture takes place.

10,488. The conditions I give you are those of the sewage?—Then I say, no. What I have stated over and over again is in regard to an admixture of sewage with pure running water.

10,489. I am quite sure you will not depart from what you said before?—No; I have nothing to withdraw upon this question

10,490. You have gone into this question of sewage and animal pollution a good deal?—Yes.

10,491. Let me ask you if you find anything to modify in the opinions you have expressed in this pamphlet, "Tidy, on River Water"?—"The two "questions we have to discuss are, first: Does the "water of a river, having been once polluted by "admixture with sewage, again, after a moderate "flow, assume its original state of purity? In other "words, does running water possess any power of "self-purification? Secondly, if such natural process "there be, what are the conditions requisite for its "fulfilment, and what are the circumstances affecting "those conditions? Let me briefly state my case, "and then proceed to call my evidence:—1. If "sewage be discharged into running water, the "organic impurities will, I contend, after a flow of a "few miles, be entirely destroyed or got rid of, the "water once again assuming its normal condition of "purity. 2. That this power of self-purification "depends upon three things: (α) On the *susbsidence* "of the suspended impurities brought down by the "sewage. Thus, in the course of the river-flow, the "grosser suspended matters will be left behind. "(β) On the presence of *animal life* in the river. "After the water has assumed a certain degree of "purity (for it is not till then that animal life "thrives), the fish in the river act as river scavengers, "and so as general purifying agents. (γ) On the

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

" *oxidation of the organic matter.* The dissolved " oxygen is derived partly (and, in the first instance, " entirely) from the air, and partly (more especially " in the later stages, when the water has reached a " certain purity, and vegetation begins to reappear) " to plant life, vegetation constituting an important " means whereby oxygen is set free in the water " itself; such oxygen is, probably, in a more than " ordinarily active condition to effect the oxidation of " the organic impurity."

After a short discussion with respect to these passages being read to the witness as the basis of questions, the Commissioners having consulted together, the Chairman stated that, although it was not evidence within the strict principles of law, the Commission would permit the passage to be read.

10,492. (*Mr. Bidder.*) I will read a short passage upon page 35, and ask you if it does not describe exactly what is taking place in this section of the Thames. It is the passage headed: " *The naked eye* " *inspection of rivers receiving sewage.*" " If we " examine a river at, and a little beyond, the spot of " sewage discharge, it will be observed that the " admixture of the sewage with the water of the " river is, at first, more or less imperfect, the line of " the sewage stream being distinctly marked for " some distance. Gradually we shall note the sewage " path widening, the edges becoming less and less " defined, until, after a certain run, the exact distance " being dependent on many circumstances unnecessary " to specify now, the mixture of river water and " sewage will be complete. But there is more than " this to be noted. The sewage at the outfall is " probably offensive, very turbid, and more or less " brown, the exact colour and degree of offensiveness " being dependent partly on the character of the sewage, " but chiefly on the distance it has travelled along the " mains before its discharge into the river, and the " extent of exposure it has undergone. Tracing the " sewage stream down the river, it will be seen to " assume a black colour, from the formation of sulphide of iron. A further short distance, and the " black colour perceptibly decreases, and, as we watch " the flow, the blackness, I had almost written yard " by yard, disappears, until at last the river water " exhibits no signs of colour, turbidity, or smell. " Once again, very soon after sewage has been turned " into a river, the sewage fungus, that most absolute " indication of the presence of sewage in any quantity, " makes its appearance in the river. Excepting this, " however, all signs of vegetable life, barring possibly " a few straggling weeds, disappear; no fish, or fish " only of a certain kind, are to be seen. The banks " and river bed become black, and branches of any " trees that by chance dip into the water, will be seen " covered with a black floculent deposit. A short " distance further down the river (and, sometimes a " very short distance indeed) the sewage fungus can- " not be found, vegetation becomes clean and luxuriant, " fish are abundant, and the river banks and the river " bed seen through the now clean water show no " signs whatsoever of that black deposit observed " higher up the river." Now, is not that the very thing that you see at Barking and Crossness?—It has not anything to do with it at all.

10,493. (*Chairman.*) Does not that description fit what you see at Barking and Crossness?—Not at all.

10,494. (*Mr. Bidder.*) Is not that what takes place in cases where the proportion of sewage is far greater in relation to the pure water than it is in the Thames?—It does, undoubtedly, take place to an extent.

10,495. But with a far greater proportion of pollution?—I do not know what the proportion of pollution is.

10,496. You instanced one case; you say, " I have " seen the River Soar, at Leicester, black with sewage; " no river vegetation being visible. I have seen it " the day following at Loughborough (a distance of " 13 miles down river from Leicester) perfectly clear, " the river banks clean, and fish abundant "?—That is quite true.

10,497. That is to say, that 13 miles run is sufficient?—Yes.

10,498. " I have seen the River Irwell, at Man- " chester, polluted with every form of filth, personal " and manufacturing. At Warrington, after a flow " of nine miles, the offensive character of the stream " had entirely disappeared "?—Yes, except that I think nine miles is wrong. I think it ought to have been 13 miles.

10,499. (*Chairman.*) Has that any bearing upon the matter?—None whatever.

10,500. (*Mr. Bidder.*) If you think that has no bearing, let us come to something that has some bearing. I will refer to B., upon page 37; " From " this appeal, to the naked eye inspection of rivers, " let me pass to certain analytical results. There is, " first of all, a remarkable fact to be noted in the " analyses of Thames water. The water at Lechlade " may be regarded as having assumed, as nearly as " possible, the character of river water. Up to this " point it will be conceded that, practically, no sewage " has found its way into the river. Between Lech- " lade and Hampton, a distance of 110 miles, the " river received (I am speaking of a few years ago) " the sewage of nearly a million people. At certain " places it is admitted that a larger quantity of " organic matter, than was present at Lechlade, could " be detected in the water. For instance, one mile " below Reading I have found a quantity of organic " matter at least double that indicated at Lechlade; " but four miles further on the water was again found " to have become normal, whilst the organic carbon " and nitrogen at Hampton, notwithstanding the " sewage of this million of people, was rather less " than at Lechlade. What, I ask, had become of the " sewage of this million people, if it had not been " oxidised during the flow of the river?" Now let me ask you a question; you do not draw back from any of these statements?—Not in the slightest.

10,501. It is the fact, that the flow of the river water of this very Thames which you are taking as the standard of purity, and which they are giving to all London to drink, has received the sewage of a million of people?—Yes, but I am speaking of a few years ago.

10,502. (*Mr. Abernethy.*) That is a non-tidal portion of the river, and the current is always flowing in one direction?—Quite so; it has nothing to do with the case.

10,503. (*Mr. Bidder.*) If the water is flowing, is there any virtue in water flowing from east to west, which there is not in water flowing from west to east?—Not the slightest.

10,504. Do you suggest that there is any advantage in a flow one way rather than in a flow both ways?—Not the slightest.

10,505. Is there any alteration in the million?—Yes, a considerable alteratton.

10,506. Is it less, or more?—It is very much less. I am not speaking exactly, but I believe it is not a tenth part of what it formerly was.

10,507. (*Mr. Abernethy.*) What is the date of that report?—That report was written in 1880, but that fact had reference to some years before.

10,508. (*Chairman.*) All these towns in the upper valley were drained subsequently?—Yes.

10,509. (*Mr. Bidder.*) Notwithstanding the drainage of this million of people (really equal to a quarter of London), the water, when the sewage was in it, was drinkable water at Hampton?—Yes.

10,510. It was not only drunk, but, in your judgment, it was drinkable water?—Yes, but I object to sewage going in.

10,511. Still it was drinkable water?—I think, as a rule, it was.

10,512. Let us get the figure into our mind, a quarter of the sewage of London?—Yes.

10,513. The water over the Teddington Weir is about seven times the volume of the sewage of London, that is what the engineers tell us?—It varies.

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

10,514. Therefore, there is a dilution of 1 in 28?—Yes.

10,515. So that in the very Thames water, whether it be that the conditions are altered now or not, one part of the sewage to 28 of river water produced, by the time it got to Hampton, a drinkable water?—Yes. That has nothing whatever to do with the question, but still I admit all that.

10,516. If I am right in my figures, what we are doing at Barking is putting the sewage in at the rate of one part in 240?—I do not admit that.

10,517. How am I wrong in drawing that inference?—As regards the mere question of quantity?

10,518. No, not the mere quantity. Why are not the same principles applicable at Barking as were applicable at Hampton?—That, of course, raises the whole question.

10,519. That is the very reason why I asked it.

(*Chairman.*) We have had it in evidence, I think, that there has been 30 days' sewage in the river at the same time.

(*Mr. Bidder.*) But what I want to point out is, that that is upon the assumption that the sewage is not destroyed. You see how the argument of the other side turns upon itself in a circle. Our argument is, that the sewage is burnt up; but the assumption on the other side is, that nothing of the kind takes place, but that once sewage, always sewage.

(*Professor Williamson.*) It is a question of words; I think the engineers apply the word "sewage" to that liquid, whatever its compositlon or condition; whether it is much changed is another question, but they refer to that liquid.

(*Mr. Bidder.*) Professor Williamson will follow me, I know, in what I say. Supposing one day's sewage has been put into the river, and has been destroyed absolutely as sewage, and the oxygen restored in the water, that is, in no sense, in the way of the next day's sewage. If I make myself intelligible, the question is, whether or not the previous sewage is out of the way; and the engineers, when they said there was 30 day's sewage in the river, assumed, as I put it, in so many words, to Mr. Mansergh, "once sewage always sewage." It was a mere mechanical deduction, assuming that the 1,000,000 gallons of sewage put in at Barking, remained there for ever.

(*Dr. Stevenson.*) On the other hand, if you assume it is diluted 240 times, that supposes that the sewage, every 24 hours, is conveyed out to sea.

(*Mr. Bidder.*) That is quite right, but I should answer it by saying there are two tides in the day.

(*Witness.*) Now, I think, Mr. Bidder asked me a question, which I am prepared to answer. The question is, why are not the same principles applicable here? Now the whole of this pamphlet refers to a non-tidal river; it refers to the admixture of sewage with pure water, and I have distinctly stated that by "pure" I certainly do not mean "salt water." I certainly do not mean "salt water." I certainly do not mean water in which the free oxygen has been reduced to a minimum, or almost so. Thirdly, I do not mean a water in which there is no vegetation.

10,520. (*Chairman.*) Those are three reasons?—But I have not given them all.

10,521. (*Mr. Bidder.*) Before we go from that, taking these assumptions, I will discuss how far we depart from them, and how far they affect the question; but I think you have repeatedly expressed the opinion that given those conditions, the percentage of sewage that you can put in is $\frac{1}{20}$th of its volume?—I think that was stated upon the 14 mile run.

10,522. You and Dr. Frankland have had some severe passages of arms upon this subject?—And it is right to say that Dr. Frankland does not agree with me in this.

10,523. I will only read the last passage in this pamphlet (*referring to the pamphlet called "River Water."*) It summarises it all admirably, and I will ask you if this is not true, and if not, how far it differs. "Given, then a fairly rapid river that has received "sewage in quantity not exceeding, say, one twentieth "part of its volume, is there evidence to prove that, "after the run of a few miles, the water of that river "will regain its purity, and become wholesome and "good for drinking? To this question I answer "unhesitatingly, there is undoubted evidence of such "purification, and the evidence I have adduced has "been of a fourfold nature: physical, chemical, "medical, and statistical." That is Dr. Tidy's parting shot at Dr. Frankland.

10,524. (*Chairman.*) Has that anything to do with a tidal river?—Nothing whatever.

10,525. (*Mr. Bidder.*) You are good enough to say that this has nothing to do with a tidal river. Why are not the same chemical processes at work in a tidal river as produce that result in a non-tidal river?—For this reason: we have, first of all, a water of a very different composition. You cannot call sea water "pure" water; you cannot call a water containing 2,000 or 3,000 grains of common salt per gallon pure water; it is a non-drinkable water. That is one thing. And though I admit that I have no absolute experiments in proof, I think it is a matter of common knowledge that salt has a certain preservative action. How far that preservative action is exerted in this case I do not know; still it is common knowledge that salt has a preservative action. Then secondly, the river is tidal, it is going backwards and forwards, that is to say, the sewage is not poured into pure water, which is the principle upon which I have been dealing; and I have in that pamphlet, which I should have liked all to be read, in summing up my conclusions said, that the primary dilution of sewage by pure water is the essential principle of the whole thing.

10,526. (*Chairman.*) The learned counsel says, why is there a difference between the pure water and the tidal river water? And you say that the presence of salt is one great reason, that it has a preservative action, and so interferes with the decomposition of the sewage; is there any other reason?—Yes, because the sewage goes into this water and renders the water itself a kind of dilute sewage. The result is that it is the pouring of sewage into sewage, and it is not an admixture of sewage with pure water. A further thing is that when that water is running in one direction, there comes a time when plant life appears; and I have always attached in this process great importance to plant life. Plants as you know set free oxygen, I do not say to what extent, but there is no doubt that (I do not use the word in the sense of raising a discussion), in a nascent condition, oxygen has an activity which it does not possess afterwards. Then we find, as a matter of fact, that the free oxygen which is in the water of the river opposite these outfalls is in comparatively small quantity, and I say again, although I have not brought forward evidence of this (but I shall, I was asked to do so), that a small quantity of oxygen has not the same activity as a large quantity, even bulk for bulk, that is to say, quantity for quantity. No doubt the particles, if they are in solution, are more separated, and absolute contact is obtained with greater difficulty, so that practically this is not a case of dilution of sewage with pure water, because it is dilution of sewage with sea water. Secondly, it is not a dilution of sewage with a water which is free from sewage, because it has contained large quantities of sewage, and the oxygen in the water has been exerted in burning up the sewage that it contained.

10,527. (*Mr. Abernethy.*) I gather from you that your observations are applied to a stream of pure water?—Yes.

10,528. And not to sewage poured into a volume of mixed salt and fresh water constantly oscillating?—No.

10,529. And not to water moving constantly backwards and forwards?—No; but in the river Thames a certain amount of oxidation no doubt does occur.

10,530. (*Mr. Bidder.*) Do you suggest that oscillation is any way adverse to the process of oxidation going on?—To this extent, that there is not the same amount of purity kept up.

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

10,531. You distinguish these opinions so as not to be applicable to the present case, by saying, "I assume pure water." Take one of your instances, the river Irwell, that you mentioned; is that a pure water where the sewage comes in?—Where the sewage came in originally, it was.

10,532. But where the sewage you speak of comes in at Manchester, is it a pure water?—No.

10,533. Is it not far more polluted than the Thames?—I do not know.

10,534. (*Mr. Abernethy.*) Do you know that the Irwell is dammed at Warrington?—Yes.

10,535. And that, below that to Liverpool it is a wide tidal estuary?—It is; I know it perfectly.

10,536. (*Mr. Bidder.*) Is not the Irwell, at the place you take as an illustration, were the sewage is discharged into it, a far more polluted river than the Thames?—It is; it is worse.

10,537. And yet the process of purification goes on?—Yes; but that has nothing to do with it. I am supposing the sewage poured in above the dam.

10,538. (*Chairman.*) It is pure water in the sense, that it is not tidal water?—That is so. It is true I was speaking of the sewage that went in at that spot, and there was sewage that went in at a spot above, and therefore it was really impure water at the point in question, but still I take it as a running water having a continual flow.

10,539. (*Mr. Bidder.*) I thought by "pure" water, you meant "unpolluted" water. Now we will keep "unpolluted" distinct from "non-tidal," and I will ask you separately. As far as "pure" means "unpolluted" previously with sewage, the Irwell, which is one of your sample cases, is a far more polluted river than the Thames; you admitted that to me?—I would not say that.

10,540. But you said it was, just now?—I will admit it might be, but I tell you I will not say it is distinctly so. I quite admit it is blacker, and looks more so, but I think that has something to do with dye works.

10,541. Now you say you would rely on vegetation; is there any vegetation below Manchester?—Yes, it does appear lower down.

10,542. Does it appear as much as upon the Thames?—Yes; I can assure you there is a great deal more.

10,543. Now, taking the tidal points, you said that when you have a deficiency of oxygen, the oxygen that remains is less energetic in its action; have you any observation, whatever, that supports that view?—I would put it in this way, in fact I did put it so, that if 2 cubic inches of oxygen have a self-purifying power equal to 4, 1½ cubic inches have not a self-purifying power equal to 3.

10,544. That is not quite what I mean; I ask, have you any observation, experiment, or result which supports that view?—I have.

10,545. What are they?—One of the learned Commissioners has asked me for them, and I have promised to bring them to him, but it is really tabulating over 5,000 analyses, according to the organic carbon, and the free oxygen present, and it is a matter of considerable labour.

10,546. (*Dr. Stevenson.*) If, as I understand, you take the Thames water as containing 2 inches of free oxygen in winter, and 1½ in summer, do you find any difference in the activity of those quantities?—I am not able to say that I do, at the moment.

10,547. Do you think that the winter oxidation is the more powerful, or the reverse?—In the summer we have vegetation, and light more active; and there is no doubt that the oxidation is then more active; but I should not like to say the exact influence of these agencies. I certainly have a very large body of facts bearing upon that question.

10,548. (*Mr. Bidder.*) You think you find the oxidation more active in summer?—Yes.

10,549. But that is when there is the lesser quantity of free oxygen?—That may account for it; that the oxygen is used up in burning up the organic matter.

10,550. That is quite the converse of what you have stated when you said that when the free oxygen was less its activity was disproportionately less?—But it has been used up probably by burning up the organic matter.

10,551. That is, doing its work?—I am not saying it is not.

10,552. Now I will pass to another question. Your Table No. 1., which you put before the Commission, unfortunately stops at Purfleet?—It does.

10,553. Why did you not carry it further down?—There is an immense deal of labour involved in doing these things.

10,554. Would not another thing have been shown if you had, viz., that as you go below Purfleet, the oxygen of the river immensely increases?—It must; there is no doubt about that.

10,555. If I might roughly represent the amount of free oxygen by a curve, I should, at Teddington, have a curve like this (*sketching a rough diagram*); then, growing very small past the outfalls, and regaining its position below Purfleet?—Yes.

10,556. Does not that mean that the oxygen has been doing its work, and that before it has got to Southend its work is complete?—Yes; but all the sewage is not discharged in that way, if you could show that it is all got rid of in that way ——

10,557. But I am putting it to you, whether it has not ceased to exist by the time it has come to Southend, and therefore does not require to go out? Before I leave this question I will show you this. If you take one of your tables, I think it is No. 10., which goes lower down the river, it is manifest that, as you go down the river, there is a recovery of the free oxygen?—It is so.

10,558. (*Chairman.*) With regard to that additional oxygen which you would find towards Purfleet, where would that come from?—I should think from the sea water.

10,559. (*Mr. Bidder.*) And also by aeration to some extent?—Yes, to some extent, possibly. There are some very curious points which I do not wish to say too much about at the moment; but there is this remarkable fact, that when you have over a certain amount of organic matter in a water, its capability of taking in oxygen is singularly reduced. And there is another very curious point, that if you take very deep well water (I have examined a great deal of Southport water, which is taken from a very deep well) when that water comes to the surface it is absolutely wanting in free oxygen, but it recovers itself and becomes saturated with oxygen in a very short time. The presence of organic matter itself changes the rapidity with which water takes in oxygen in a very curious manner.

10,560. (*Mr. Bidder.*) If the Commission will compare Table No. 1 with No. 10, they will see on Table No. 1, which begins at Teddington, that up at Teddington, although we begin with a fluctuation, yet it is practically about 1¾ inches of free oxygen. That goes down with fluctuations, as this table shows, until at the outfalls it is down to ·7, and according to that table, at Erith, down to ·5?—Yes.

10,561. Then if we go to Table 10, and carry the thing on, Table 10 gives no low water on a certain day. North Woolwich is the highest point there, and is fairly accordant with Table 1. I will take the "one foot below the surface at low water," 1·15 of free oxygen, and then in the next place the southern main drainage outfall.

(*Mr. Lumley Smith.*) That ought to be a little higher in the table; is it out of position.

10,562. (*Mr. Bidder.*) At that part it is ·58. Then we go to Erith "one foot below the surface at low water," ·62; and then at Gravesend "one foot below the surface at lower water" ·66; and then, if we go to Southend one foot below the surface, it is 1·2?—Yes.

10,563. That justifies, as I say roughly, my curve?—Yes, I admit that.

10,564. I want to ask you, as a chemist, the signifi-

cance of this curve, does it not mean that the water charged with oxygen has been doing its work burning up the organic matter in the water, and that before it has got to Southend, the oxygen has mastered the sewage; the sewage is decomposed, and therefore the oxygen rises to its normal?—Yes, when the sewage does arrive at Southend, I am bound to say that I think a great deal of it is mastered.

10,565. (*Mr. Abernethy.*) Is not the river at Southend a wide tidal estuary?—Yes, very much so.

10,566. With an enormous body of pure sea water flowing in every tide?—It is so.

10,567. (*Mr. Bidder.*) I am obliged to Mr. Abernethy for pointing that out. (*To the witness*). That wide tidal estuary supplies the water which comes up the river every tide, and that is pure sea water?—I do not call it pure sea water.

10,568. (*Mr. Bidder.*) Let me refer you to page 580 of what you said upon a former occasion, upon the Mud Inquiry. At question 5921, I put this question to you: "Given the state of the Thames and "the brackish water, there being two hundred "volumes of water to one day's sewage, it will be "burnt up," and your answer was, "Yes." Then Mr. Aston, another of the counsel put to you this question again: "All the suspended parts will be burnt up, you say" and your answer is, "Yes"?—I could not have meant that from any point of view; I must have misunderstood your question.

10,569. (*Chairman.*) You say it would not be burnt up?—Not entirely.

10,570. (*Mr. Bidder.*) Your own counsel puts it to you "All the suspended parts will be burnt up"?—I am sure I should not have said yes to that.

10,571. But you did. Upon that occasion you were trying to fix us with the responsibility for the mud. You were not then dealing with the suspended particles. You were trying to show that that which did not sink, but remained suspended was burnt up, and that the balance sank?—It does get burnt up in time, no doubt, but when I am made to say that where there is one part of sewage to two hundred parts of water it will be burnt up, I could scarcely have meant that.

10,572. (*Mr. Abernethy.*) What part of the Thames do you refer to?—The part of the river where the sewage was put in. I do not particularly object to that as a matter of fact, because I should accept it generally.

(*Mr. Michael.*) You are talking about oxidation by the air of the river.

(*Mr. Bidder.*) Now, I want to get another thing which we have not got before the Commission. In the peculiar circumstances of the London sewage, a very large portion of that fæcal matter, in your judgment, is burnt up long before it gets to the outfalls at all?—I think some of it is. I never said a large portion of it is; I have no doubt I said that a primary putrescence took place.

10,573. Pardon me; Mr. Bramwell, one of the arbitrators, was examining you?—Which question was that?

10,574. That was at 5901. Now I will refer to question 5885. I asked you, "Speak of the thing as a whole as you are so fond of doing," and you replied, "I cannot take the numbers, that which goes to the "bottom is no doubt oxidised slowly, but very slowly. "(*Q.*) That which did not go to the bottom?—(*A.*) "That which did not go to the bottom is no doubt "carried backwards and forwards, and no doubt does "become oxidised, provided it has a sufficient run. "I have never fixed a run of less than seven miles "upon any occasion. (*Q.*) Do you suggest it has "not a sufficient run in the Thames?—(*A.*) No. I "am bound to say this, that every particle of sewage "which is in suspension in the water,—I will put it "this way if you like,—I honestly believe, is entirely "destroyed long before that water reaches Hampton"?—That has nothing to do with the tidal portion of the river; that is at Hampton.

10,575. No doubt that is so; but look on a little farther. Now, I go on at No. 5888 to ask you with regard to the sewage in the Thames: "Then, similarly, "discharged sewage into the stream of the Thames "at high tide, which has got six hours' ebb—say two "miles an hour—14 or 15 miles run, into 200 times "its volume of water, may I say there, in your belief, "every particle of sewage matter is destroyed by the "time the tide is down?—(*A.*) No, I am not prepared to say that, that is another point of view. "First of all we have not pure water to start with. "The material first of all comes in and pollutes it, "and it gets worse a great deal, and the result is we "get different conditions." Then I asked you, "According to you it gets worse and worse?" and you replied, "Yes." Then Captain Galton asked you this question, "Does the salt in the water—the "brackishness of the water—of the Thames, affect "the question of the decomposition in the lower "reaches?" to which you replied, "It does to some "extent." Then Mr. Bramwell asked you the question, "Which way?" and your answer was, "It "prevents decomposition, no doubt, to some extent. "There is another thing; a great many of these "samples have no smell, as a rule I may say there is "no smell. There is no doubt about it. In the first "instance one was rather struck with that fact, but "on further consideration it was quite clear that one "of the reasons why that should have no smell was "first of all the peculiarity of this sewage, which we "do not find in large towns generally. It has to "travel a very considerable distance before it reaches "the outfall. In other places, as a rule, the people "live immediately on the banks of the river, and "there is very little or comparatively no distance for "the sewage to travel. That is the first fact. The "result is that in all sewage matter there are very "different forms of organic matter. There is an "organic matter which is highly putrescible, where "putrescence sets in immediately, and that organic "matter that is so highly putrescent is divided by an "absolutely sure line from another kind of organic "matter in which the putrescence is comparatively "slow, and there is a third kind even which I have "noted, where you get, after the second putrescence "has set in, a distinct line of demarcation, and then "putrescence sets up again. Now, it is a very "curious fact that when that sewage is discharged at "the outfalls of the Metropolitan Board it has flowed "a very considerable distance. (*Q.*) Six or seven "miles?—(*A.*) Nine miles, we will say; the primary "putrescence is very nearly at an end." Now, notice this, and see if I was not justified in using the phrase I did. Then I asked you, "That is to say, a large proportion has been already burnt?", and your answer was, "Yes; but when it comes out in a very "short time indeed, all the gases are given off, in "goes the water and takes its place, and down goes "the material." So that you were of opinion then, that in the case of London sewage, by the time it got to the outfalls a large portion of the organic matter was already burnt up?—Yes, a large portion was, and I accepted it in that sense. It is not true, but I accepted it.

10,576. (*Chairman.*) Is it true?—The phrase, "a large portion," is a very indefinite phrase.

(*Mr. Bidder.*) It means more than half.

10,577. (*Chairman.*) Do you adopt this unreservedly?—I should not like to say that "a large portion" had been already burnt.

10,578. (*Mr. Abernethy.*) How can you account for the organic matter of the sewage being burnt up within the sewers?—I think this refers to primary putrescence; putrescence is not oxidation. One is a little disposed, unfortunately, to adopt a question when it is asked.

(*Mr. Bidder.*) But you adopted also a phrase in the question of Mr. Bramwell which meant oxidation, "a large portion has been already burnt."

10,579. (*Chairman.*) By "burnt" you meant

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

"oxidised"?—Yes, by "burnt" I meant "oxidised." I ought not to have accepted the question altogether in that sense.

10,580. Putrefaction and oxidation are distinct things?—Yes, as a matter of fact putrefaction is not oxidation.

10,581. (*Mr. Bidder.*) Let us not quarrel about words. Be it oxidation, or be it putrescence, it is resolved into a gaseous form?—Yes.

10,582. And ceases to exist as sewage in the water?—Yes.

10,583. (*Prof. Williamson.*) Is it your opinion that the nitrogenous matter in fresh sewage is converted mainly into gaseous matter when it reaches the outfalls?—No, but I think that there are in sewage matters of varying putrescibility. For instance, there will be a primary putrescence going on in the sewers themselves.

10,584. The urea being converted into carbonate of ammonia?—Yes.

10,585. But the carbonate of ammonia does not evaporate?—No.

10,586. Is there any conversion into gaseous matter worth mentioning in the sewers?—No. But there is another thing which struck me that sometimes the sewage in a sewer smells so strongly and that when it comes out it does not smell, and I could only explain it by the fact that the primary putrescence was at an end. And then I would just say another thing, that at the time I stated that, I had very large quantities of sewage under observation, and I found there was a smell produced for a short time by the primary putrescence, that there was then a period when it did not smell; and that then putrescence set in again as though there were bodies in it of different degrees of putrescibility. That was in my mind at the time.

10,587. (*Mr. Michael.*) You stated that there was a secondary putrescence?—There is what is more curious still; there is a tertiary putrescence.

10,588. (*Dr. Stevenson.*) Would you find that the urea had entirely disappeared when the sewage reached the Thames?—I could not say that.

10,589. Would any great portion of it?—I should not think so; I think some of it would.

10,590. That formed one out of the three and a half ounces of solid matter?—Yes; but I did not use the word "a large portion" myself. It was a question that was put to me, and I certainly adopted it. I must therefore, admit that I did answer in that way.

10,591. (*Chairman.*) You modify that by saying that the word "large" was wrong?—Yes; but of course there was the other point of certain muds not smelling, which was very remarkable; that on taking the sewage from the sewers themselves and operating with that mud before it had passed through a long line of pipes, I found effects of that kind produced, namely, that I got a very disagreeable smell, and then the smell ceased, and so on.

10,592. (*Mr. Bidder.*) Now do not suppose that I want to catch you upon any unguarded acceptance of the question upon a former occasion; but I want to put it to you now, whether you are not prepared to say that that which is burnt up upon the way to the outfall is at least half of the sewage?—I have no facts at the moment to support that statement, but I do not believe it for an instant.

10,593. The river being what it is, and the sewage being put in in the way it is, do you find anything either in this table or in your observations upon the spot or in your experiments, which leads you to believe that the condition of the water or the emanations from the water before it reaches the Thames are injurious to health?—I have not studied the matter from the point of view of injury to health.

10,594. You are an officer of health for one of the London districts, are you not?—I am.

10,595. Before you make any speech will you follow me. I want to put it distinctly before you. You are an expert and a scientific witness, and a health officer, employed in this case to examine the river and take analyses of all kinds up and down the river in the region of the outfalls, and I invite you to tell the Commission whether there is any element of injury to health in the condition of the river?—I say at once that is a point of view from which I have not regarded the matter. I have not sought for statistics upon the subject, but I say that throwing 400 tons of sewage into the river undefœcated, when the whole of the solid impurity could be so easily removed, and the effluent made just as pure as the normal condition of the river, must produce a mass of emanations which I should think, from *a priori* reasoning, must be injurious to health.

10,596. Would you mind instead of 400 tons saying a tenth of a grain per gallon?—No, I say it is 400 tons daily.

10,597. Did you ever know a case in which injury to health was caused by emanations from sewage in the water of a river even worse if you please than the Thames?—Had I thought you would have asked me that question I might have looked it up; but as a matter of fact I have not looked it up.

10,598. Taking your experience of the filthiest river you ever knew, did you ever know such a case?—I have no facts at the present moment upon the point. I have not regarded it from a hygienic point of view.

10,599. But you have been going into these points all your life; have you any experience of the emanations from sewage in the water of a river being injurious to health?—I have none myself; but it is a matter upon which evidence will be offered to this Commission.

10,600. As a whole, what do these concrete observations which you have laid before the Commission upon the main question point to? That there is sewage there we know, and that the sewage is being burnt up by the oxygen we know, but what do they show with regard to the injury to health?—I have no evidence of its being injurious to health one way or the other.

(*Chairman.*) The witness has stated four times that he has no evidence of its being injurious to health, I do not know why you should wish to have it five times.

10,601. (*Mr. Bidder.*) Do you believe for instance from what you find by your chemical analysis or from observation, that the state of the river is injurious to health?—I cannot give you any information at all upon that point

Re-examined by Mr. Lumley Smith.

10,602. I will confine myself to what seem to be the more important matters without going into any great detail in your examination. First of all, with regard to the evidence that you gave based upon the microscope, I shall only put one question to you, and that is whether the results you get from the microscope are in any way what are called quantitative. I think you have already answered that they were not quantitative?—They are not.

10,603. Will you just explain what you meant by that?—That I was unable to say that there was so much sewage matter in this part of the river, or so much sewage matter in that part of the river, and so on, by means of a microscopic examination. Absolutely quantitative they are not.

10,604. Are they in any respect quantitative?—Yes; I said in my evidence in chief that they were relatively quantitative; I made a point of that, if you remember.

10,605. Will you explain a little further what you mean by "relatively quantitative"?—Supposing I start from Barking and take the deposits in the water, and find that from Barking to Deptford I get abundant evidence of free spiral vessels, and of a very large quantity of this yellow amorphous material in every sample; then supposing I go from Deptford to London

Bridge and I find that I get evidence of materially less amorphous matter, and that I get spirals in every other sample; then supposing I go from London Bridge to Battersea and I find the spirals in every fourth sample; I have a relative means of estimating the quantity, although not an absolute means. That is the fact as I stated in my evidence in chief. Starting from Barking and working upwards, the quantity of spiral vessels gradually decreased.

10,606. That I think may enable you to compare different parts of the river, though it does not enable you to know at any part what quantity there is of any particular material?—Certainly not, absolutely.

10,607. The allusion to the microscope brings us to another point. My learned friend, Mr. Bidder, asked you if you had not traced in the water the yellow amorphous material as far as Chiswick, and whether in the mud inquiry you had not traced it as far as Teddington?—Yes.

10,608. He also asked you whether the relation of nitrogen to carbon did not vary in your evidence with regard to the water from what it had been with regard to the mud?—It did.

10,609. Are there any sources of difference between water and mud which would justify you in finding elements of difference between the two?—I do not think the two are comparable.

10,610. The fact that you find an increase or a decrease with regard to the mud as compared to the water does not enable you to compare the one with the other?—No; the one being solid and the other liquid, I do not think you can compare them; they are subject to such different influences.

10,611. My learned friend pointed out upon your table a portion of the river between Nos. 29 and 35, that is between Blackfriars Bridge and Deptford, which he christened "specially polluted?"—Yes.

10,612. As far as matter in suspension is concerned, that appears to be so by your table?—It does appear to be so.

10,613. Does that increase apply with regard to the other columns?—No, it does not. That is to say, taking the organic carbon and the organic nitrogen, they in no way follow the same rule as the quantity of suspended matter; his observation therefore is entirely limited to the suspended matter.

10,614. However, whatever may be the cause it must be due to some local causes?—I think so. I do not know the cause as a matter of fact.

10,615. You are not aware that there are storm sewers or overflows, and so on, in that part of the river?—No.

10,616. Now I will go to what we are told now is to be the platform of the battle, that is, the free oxygen. My learned friend Mr. Bidder put some questions to you as to whether the amount you had given as the quantity of free oxygen at Teddington, which was 2 cubic inches per gallon, was always the amount that was found, and you said it varied from time to time in the year; but referring to your table which is before the Commission, which contains your analysis from Teddington to Purfleet, that is based, I believe, not on an estimate of 2 cubic inches to the gallon, but upon the actual observation of 1·710 at the top of the table?—They are actual results.

(*Mr. Michael.*) We never suggested it was an estimate.

10,617. (*Mr. Lumley Smith.*) That table is based upon the absolute observation of 1·710 at Teddington, that being what was found upon that particular day; and the chart which follows, I think it was No. 3, is based upon the analysis of that table, No. 1?—It is.

10,618. So that neither the table with the analysis, nor the diagram A, depend at all upon an estimate, but upon actual analysis?—That is so.

(*Mr. Michael.*) We never suggested it.

10,619. (*Mr. Lumley Smith.*) If that be so, it seems to make my learned friend Mr. Bidder's questions a little irrelevant. (*To the witness.*) Now, with regard to free oxygen, I presume the experiment has to be carefully made for the purpose of determining the amount of free oxygen in the water?—Yes.

10,620. Now before we pass on, do free oxygen and dissolved oxygen mean the same thing?—Yes.

10,621. It is the oxygen which is not taken up to form the water?—Not combined with anything else.

10,622. I rather understood you to say that it is better to analyse as soon as you can, in order to avoid the risk of fresh oxidation?—Undoubtedly. I should myself have preferred to have examined the free oxygen on the spot. Had bottles been only partially filled and a space left, I should have attached, I will not say no importance, but very little importance comparatively, to the amount of oxygen determined; but as a matter of practical knowledge, I know that if you take it in a certain way, and fill the bottle, you may arrive at it with a fair degree of accuracy.

10,623. It would be better to do it in a boat if it were possible?—Yes; but one heard stories about laboratory boats going down that I preferred to do he determinations away from the river.

10,624. (*Professor Williamson.*) Were they all taken at the same interval after the water had been collected?—Yes; the principle I adopt is to bring the samples home with me and to do them the first thingin the morning.

10,625. The same number of hours intervenes in each case between taking the sample and making the analysis?—Yes, practically. I could not say the same exactly, owing to the different time of the tide; but practically the same number of hours intervenes.

10,626. (*Mr. Lumley Smith.*) With regard to the wave or curve which my learned friend Mr. Bidder spoke of, there is practically rather less free oxygen in the sea water than there is in the water at Teddington?—Clearly; but you may say practically they are the same.

10,627. If you find as you go further down the river that the free oxygen becomes less, that may proceed from sewage coming into the river?—It may.

10,628. I presume it must arise from some local cause or other?—Yes.

10,629. The mere admixture of sea water would not necessarily alter the amount of free oxygen very much?—It would not.

10,630. Then with regard to this wave, if there is a depression in the wave between Teddington and Southend, that would show that, owing to local causes, there had been a diminution of oxygen?—Yes, that is so.

10,631. Then as you get a little further on from the depressed part of the wave, when you find the free oxygen begins to improve, does that necessarily result from the operation of the air, or from the flow of the sea water having come in and diluted the body of impure water that was in the river?—I should think it was both.

10,632. Then it does not necessarily follow that if you find a few miles below the outfall the free oxygen is beginning to improve, that the fresh oxygen has come in from the air, but it may have come in from the sea water?—Yes.

10,633. I find, in point of fact, that your chart No. 1 does not go below Purfleet?—It does not.

10,634. But a little later on we have samples showing the amount of the free oxygen at Southend, and also at Margate?—Yes.

10,635. If you look at your Table 10 you will find that the free oxygen a foot below the surface at Southend pier at low water was 1·21?—Yes.

10,636. That is a good deal less than the free oxygen at Teddington?—Yes.

10,637. The free oxygen at Teddington was 1·7?—Yes.

10,638. So that as far as your wave is concerned the sea end of your wave would hardly get up as high

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

as it was at Teddington?—I very much doubt whether it would.

10,639. If you turn over to the table a little further on you will find the amount of free oxygen at Margate?—That is Table 3, page 4.

10,640. There I find that at Margate the dates are different. They give the amount of free oxygen at Margate as 1·6, which is rather better than at Southend?—Yes. And again, when I take the water at Brighton, it is better still.

10,641. So that if the sea water which comes in at Southend had originally as much free oxygen as water coming in at Margate, it would show that the sea water had been reduced in oxygen by meeting with the Thames?—Yes.

10,642. Now the water does not even at Southend appear to have got up either to the amount of free oxygen that we find at Margate, or that we find at Brighton?—No, it does not.

10,643. I think I might ask you this general question:—As regards going down the river, my learned friend asked you what were, what he called, the "reliable elements" from which you might judge the pollution, and then he took each by itself to see what amount of importance should be attached to each. What is your view with regard to the principal elements to be considered in coming to a conclusion as you go down the river; I presume it is not a simple matter in any way?—What I have stated is that I do not think you can judge of the purity of a water in any way from any single constituent, or from any single detail. You cannot judge it by the organic carbon. I could tell you of an organic carbon of ·9, which is a splendid water. You cannot judge it by organic nitrogen alone, nor by free oxygen alone, nor by ammonia alone; but in every case in the matter of any analysis you must judge of the whole analysis. And let me say, with all due respect to Mr. Bidder, that the details that he dealt with, which I admit do show inconsistencies if you take them in detail, have nothing whatever to do with the case. I look at the water as a whole, and I will refer to this diagram. There is a section in which I admit there is no great alteration in the organic carbon; the oxygen keeps it in check; but I find the organic carbon enormously rises in that section of the river (*pointing to the diagram*), and concurrently with that rise of organic carbon in that section of the river, I have a fall in the free oxygen. It is, if I may be excused for saying so, ridiculous to look at any one single thing and draw deductions from that; you must look at the whole. For instance, in a water 50 grains of common salt may mean nothing; but, on the other hand, even five grains may mean serious pollution. You cannot judge by one single constituent; you can only arrive at a conclusion from all together. It is rather remarkable that in my long cross-examination I have never been attacked upon the general results of my analysis, the organic nitrogen going down as the organic carbon rises. And, moreover, there is another thing which has not been put to me in cross-examination which is very important. One statement I made, which I thought would have attracted Mr. Bidder's attention, was that one difference between sea water and sewage as regards its composition was the presence of ammonia, that the ratio of nitrogen to carbon is not very different, but that ammonia is absent almost entirely in sea water and present in sewage. Now ammonia is one of the elements of analysis which is to be taken into consideration; so that what I wish to make clear is that, although I admit (I do not think there would have been any truth in the results if it were not so) that taking any one single thing you may get great differences which may seem to upset the value of the analysis, it is only when you put the facts together that you can get an accurate opinion, and I say that, taking all the facts, from Teddington downwards, you have a singular concurrence of results.

10,644. Do you find any absolute law in the case of the water in any of the columns, or do you find anomalies?—I find anomalies, and I do not think that could be helped. Of course it would be much prettier to have a definite line, but that cannot be obtained. I can only say those elements are there, and if you ask me for an explanation I cannot give it.

10,645. Erith has more than the usual fluctuations?—I do not understand Erith at all; it is one of the difficulties in the river.

10,646. (*Dr. Stevenson.*) With regard to the ammonia, we all admit that the nitrogen of the sewage becomes converted into ammonia, but do you think any difficulty would arise from that?—It would evaporate or perhaps be oxidised.

10,647. You would regard the ammonia as an index of the amount of oxidation which the river, plus the sewage, has undergone; is that so?—No, I do not think I should. If I knew how much of the sewage was there at the starting point, and how much was afterwards absent, I could tell what oxidation had taken place. The difficulty I am bound to confess in the matter of ammonia is that when you bring a bottle home containing water I think the ammonia is far less probably than it was when it was put into the bottle.

10,648. Would it be oxidised, or what would have become of it?—Some of it would; therefore any details about the ammonia certainly will fall short of the actual facts.

10,649. (*Mr. Lumley Smith.*) You assume that there is far more ammonia in the water when it is taken out of the river that when it gets into the laboratory?—Yes.

10,650. And that is all in favour of the water?—Yes.

10,651. Now I will ask you another question. I believe you have been always strong upon the burning up theory. It is a well-known fact that in all the discussions with regard to water this has not been an absolutely admitted proposition, but is a matter upon which chemists have held different opinions?—Yes; and here I have opposed to me men of far greater experience and far more learning than myself.

10,652. (*Chairman.*) It is a contestable question in science?—Yes.

10,653. (*Mr. Lumley Smith.*) My learned friend talked about your last paragraph in one of your pamphlets as being a parting shot at Dr. Frankland. You and Dr. Frankland have generally been upon opposite sides?—Yes, upon this question. I do not wish to put my theory forward as absolutely proved, because Dr. Frankland holds different views upon the point.

10,654. Now a few words as to the extent to which the sewage is purified by contact with pure water. My learned friend suggested that the sewage of a million persons went into the water above Teddington Weir; that would be distributed over the district from Teddington to Lechlade, and so on——

(*Chairman.*) What was stated was that some years ago that was about the number.

(*Mr. Michael.*) Since that time great changes have occurred by the sewage being treated in many places and applied to the land.

10,655. (*Mr. Lumley Smith.*) That sewage is spread over 120 miles?—150 miles, I think, would be nearer the mark.

10,656. Occupying, I am told, 3,000 or 4,000 square miles. Now, would the effect of the sewage coming in from a village, and having the river to itself for seven or eight miles, be to purify it vastly more than if it were poured in in a vast mass at one spot?—Yes, certainly it would.

10,657. A few years ago did the sewage come in through drains? There were cesspools largely used in those days, were there not?—It came in anywhere.

10,658. Now a question has been asked about the River Irwell. It has been suggested to me that the water of the River Irwell, before it takes its final leap into the estuary, passes over a number of weirs; the number of nine was suggested to me?—Yes.

10,659. Would that have the effect of accelerating the oxidation process?—Yes; that will be one of the

questions I shall have to draw the attention of the Commission to when I deal with the question of the inch and a half of free oxygen. Taking the Shannon, where we get the Doonas Falls, and where we increase the oxygen from 1·2 to 2·1 cubic inches per gallon, I shall endeavour to show you the enormous alteration that takes place in the organic carbon consequent upon the increase of the free oxygen in the course of the Falls. One part of the evidence which I shall endeavour to lay before the Commission bearing upon that point will be that I shall take a section of the river where I get, say, 1·2 of free oxygen and show the organic carbon at different spots; then I shall take another point, where by means of the Doonas Falls I raise the quantity of the free oxygen and show the effect of that quantity of free oxygen upon the organic matter.

10,660. Now with regard to the sewage being burnt up, my learned friend asked you if half the sewage was not burnt up before it got to the outfall, and you said you did not believe it?—Certainly not.

10,661. Have you ever heard it suggested before?—No, I am quite sure nobody on the other side would suggest it.

10,662. Probably you are of opinion that when the water gets to Southend it is not a nuisance then?—I do not know Southend, but I should think not. As a matter of fact, sewage, or a mixture between sewage and sea-water, does form a very disagreeable mixture, a very offensive mixture indeed, owing to the reduction of the sulphates and, I think, to the setting free of sulphuretted hydrogen even in quantities which you cannot detect by the smell, because when you dilute sulphuretted hydrogen to a very great degree of dilution, so that you cannot even smell it, it still acts injuriously upon animal life.

10,663. When the sewage gets to Southend it has gone through what I may call the "horrors of the middle passage"?—Yes.

10,664. And the oxygenating process may be attended with nuisance from the purifying process; is that so?—I do not think oxidation can be attended with nuisance.

10,665. But during the progress up and down the river, when it was getting oxidised, the nuisance would arise?—The nuisance would arise, not from the oxidisation, but from the putrefaction.

10,666. Now one word with regard to some experiments which you were said to have made some time ago with regard to the free oxygen in the Thames water. Any slight matter, such as the bottles not being properly filled, and so on, would affect the result?—It would. Of course I quite admit that this question of free oxygen has only materially interested one in the last two and a half years, and I can imagine therefore such a number of things which would interfere with the accuracy of these results.

10,667. You were asked also a question about the quantity of suspended matter in sewage, and you have referred to a storm as to which Mr. Keates gave an analysis; have you referred to see the quantity of water which fell upon that occasion?—I think it was a quarter of an inch.

10,668. I think the only other question I have to ask you is this: Have you brought that which you promised to bring, viz., the analysis of the wells at Grays?—I cannot say that I have. I have the quantity of salt present in the Grays water which I can give to you as 13 grains.

Examined by the Commission.

10,669. (*Dr. de Chaumont.*) I was desirous to ask you some questions about the microscopic part of your examination. I wish to ask, with regard to the objects you found here, some of the reasons upon which you base the statements you make, especially with regard to the yellow amorphous matter which you seem to consider animal matter broken up an indication apparently of sewage; what was the exact ground upon which you made that statement?—I say that this deposit, which forms the most conspicuous microscopic feature of the samples of sewage mud and of a sewage water-deposit, is undoubtedly of animal organic origin. It always assumes a yellow tint (in fact, the precise tint seen in masses of disintegrated muscle), and is amorphous or faintly granular. It is entirely unlike the fine sharp angular fragments seen in unpolluted muds and deposits; these latter particles, under a high power, refracting light conspicuously, a circumstance that at once distinguishes them from the amorphous matter under consideration. The deposit precisely resembles the molecular matter that we have observed to result from the utter disintegration of *animal* tissue, more especially if kept under water. A great deal of that was the result of taking particles out of the dissecting room and keeping them under water for experiments. It was a very long series of experiments. In the case of disintegrating vegetable tissue its tendency is to break up into *fibrillæ*, more or less coarse, and not into the peculiar amorphous material described. It is exceptional, however, to find any traces of *fibrilla* amongst this particular deposit. It may be urged that isolated and young vegetable cells would exhibit no such breaking up into fibrils.

10,670. With regard to amorphous material of this description, have you never found, for instance, in a deposit of well-water, similar yellow matter which it would be almost impossible to say was sewage?—I do not think I have. I think I know the kind of deposit you are referring to; but if it were like that I should say it was animal.

10,671. I suppose you applied re-agents to it?—Yes; and I would say I tried staining materials with all these things, using hœmatoxylin chiefly for the purpose of bringing out the animal matter more completely.

10,672. (*Dr. Stevenson.*) You spoke of "yellow "amorphous matter," and "yellow matter"; you connect them both with muscular fibre, do you not?—Yes.

10,673. How do you connect the yellow amorphous material with muscular fibre, beyond what you have just said, you do not trace the intermediate changes, do you?—I do not. Some of these masses are very peculiar; some of them have definite outlines; in other cases the outlines are indistinct. Whether it means that that is passing into that stage I am unable to say. Here is a singular blending of those examples (*explaining the same upon the diagram*).

10,674. You attributed the colour somewhat to bile, I believe; have you at all tried to find out whether it contained iron?—I have not.

10,675. (*Dr. de Chaumont.*) You did not apply for instance hydro-chloric acid to them?—I cannot give you the result, but I have tried almost everything.

10,676. It was suggested to you in your examination that the deficiency of oxygen in the water was one of the causes of the death of the fish, but you did not in your answer mean to imply that the fish might not also have been poisoned directly by the water?—Certainly not, I do not know as a fact to what extent the oxygen must be deficient to prevent fish life; but I am equally certain, first, that there may be varieties of organic matter which may be themselves poisonous; and secondly, I am equally certain that the formation of sulphuretted hydrogen in the water owing to the action of the carbonic acid on the reduced sulphates would undoubtedly be poisonous to animal life. As a fact a very minute quantity of sulphuretted hydrogen put into the water of an aquarium will kill all the fish.

10,677. (*Dr. Stevenson.*) There is one question with regard to the oxygen I wish to have made clear,

*Dr. C. M. Tidy, M.A., M.B.*

28 Feb. 1883.

and that relates to questions 9957 and 9958. You mentioned that in one portion of the river there is a very large increase of organic impurity and that "the quantity of free oxygen is not very different "from that of the previous reach." Then you went on to say that "the water had been trying to keep "itself pure, it had had a struggle." Do you mean to say that when there is a certain quantity of sewage poured into the river, the oxygen ceases to be absorbed by the water; or is it absorbed and immediately destroyed by the sewage?—If I follow your question rightly, what I mean is when the oxygen is there, and the sewage is there, the sewage trying to pollute, and the oxygen to purify, that, for a long time the oxygen succeeds in keeping down the quantity of the sewage, but that there comes a time at last when the oxygen is incapable of keeping down the sewage.

10,678. In other words oxidation is going on very rapidly?—I mean that the sewage gets over and above the oxygen. There is an oxidation undoubtedly but that oxidation is very much less when you decrease the quantity of oxygen.

The witness withdrew.

*Mr. Michael* applied that Mr. Mansergh's plotted cross sections should be handed to the counsel for the Metropolitan Board of Works as had been previously, as he alleged, promised.

*Mr. Balfour-Browne* stated that he was instructed that the furnishing of these cross sections would put his clients to the expense of 1,000*l.*

*Mr. Lumley Smith* stated that he had not the slightest objection to the counsel for the Metropolitan Board of Works having access to them, but that what he objected to was to having do any work for the other side.

*Mr. Michael* stated that he did not wish at the moment to make copies, but merely to be permitted to to examine the sections.

*The Chairman* inquired whether Mr. Mansergh would have any objection to leaving them with the Secretary and letting them be examined.

*Mr. Lumley Smith* stated that Mr. Mansergh would leave them with the Secretary to the Commission for the inspection of the other side.

*Mr. Michael* stated that for the present he would content himself with his right to examine without asking for permission to make copies.

Dr. Edward Frankland, Ph.D., D.C.L., M.D., F.R.S., examined.

*Dr. E. Frankland, Ph.D., D.C.L., M.D., F.R.S.*

10,679. (*Mr. Lumley Smith.*) I believe you are Professor of Chemistry in the Normal School of Science and Royal School of Mines?—I am.

10,680. And Past-President of the Chemical Society and the Institute of Chemistry?—I am.

10,681. You were, I believe, one of Her Majesty's Commissioners appointed in 1868 to inquire into the pollution of rivers, and the best means of remedying it?—I was.

10,682. I think that was a matter which occupied your time for upwards of six years?—For about six years we were engaged upon the inquiry.

10,683. How long have you been acquainted with the water of the river Thames?—I have known the river Thames since the year 1845.

10,684. When you say that you have known it, you mean that you have not merely known it casually, but your attention has been directed to it?—Yes. In the year 1845 I used to cross it twice daily, and I have always taken notice of the condition of the river. I cannot say that so long ago as that I had any special object in noticing the sources of pollution of the river; but I noticed the extent of it.

10,685. It is a matter of common knowledge that, until the sewage was diverted from London the state of the river, as it passed through London, was bad?—It undoubtedly continued to diminish in purity until the time of the opening of the main drainage outfalls.

10,686. And since that time the condition of the Thames in London has improved?—The condition of the Thames in London has improved. After the opening of the outfalls the river markedly improved in purity; but since that time, from soon after the main drainage outfalls were opened, the purity of the river in London has been decreasing.

10,687. Did you make any inspections of the river in 1879?—Yes, I did, several.

10,688. How came you to make those inspections?—At the request of the Thames Conservancy I made several careful inspections of the river between West Moulsey and Erith.

10,689. Did those inspections make you acquainted with the state of the river for the whole of that distance?—Yes.

10,690. Beginning at the top, above Teddington Lock, where the water comes over Teddington Weir, in popular language, what do you find to be the state of the water?—Popularly speaking, the river is there a pure or unpolluted stream.

10,691. You have compared, have you not, the mud of the Thames there with that in other places?—Yes, we took a number of samples of mud, from the highest station to the lowest; we also took mud from the Mole, which is an important tributary of the river Thames. The latter contained only 2·63 per cent. of organic matter, and nearly the whole of that was of vegetable origin. We also took a sample at Hampton, as illustrating the mud of the unpolluted Thames; that contained 11·33 of organic matter, which consisted, to a great extent, of decaying leaves.

10,692. The mud of the upper Thames was chiefly vegetable?—Yes.

10,693. Then, when you got below Teddington lock, what did you begin to find?—The appearance of the river began rapidly to change for the worse; the water became muddy, and the mud became richer in organic matter, and that organic matter in the mud proved, upon investigaaion, to be more and more impregnated with animal matter as we went down the river. Opposite Deptford Creek the mud also exhibited an enormous number of red worms, known technically as blood worms, which I have always found to be characteristic of sewage matter in mud; they used to be very abundant about Hungerford Bridge. The mud there used to be quite red upon a fine sunny day, and if a stone were thrown into it the mud became instantly gray from the worms sinking below the surface.

10,694. Now, with regard to Hammersmith and Chelsea, have you anything to say with regard to the water there?—I have nothing to say, except, in general terms, that as we went lower down the river, the water became more and more polluted.

10,695. With regard to these blood worms, have you found them anywhere else, except off Deptford Creek?—Yes; we found them in the mud off Blackwall Point, at the dry dock there; and there also offensive gases began to rise to the surface, and the discharge of those gases increased as we neared the two Metropolitan outfalls at Crossness and Barking.

10,696. Dr. Tidy mentioned having been with you upon one occasion; do you remember that?—Dr. Tidy was there with me upon every occasion.

10,697. Do you remember what time of the tide it was when you were opposite Barking and Crossness?—When we were opposite Barking outfall it was dead low water, and, to my surprise, I saw at that time a very large volume of sewage being discharged into the river, because I had imagined previously that the sewage was only discharged during the first two hours or so of the ebb tide. I judged from the amount flowing out there that it would be between 20,000,000 and 30,000,000 gallons in the 24 hours.

10,698. And that, you say, was at dead low water?—Yes, that was at dead low water, just before the tide turned.

10,699. Was that offensive in any way?—Yes, there was a very offensive smell there.

10,700. Passing down the river, did you trace the effects of sewage in any way?—Yes, the effect was traceable down to Erith; the mud at Erith exhibiting decided evidence of animal matter in it.

10,701. Then you stopped at Erith, I believe?—Yes, we did not go further down.

10,702. That was in 1879—now, in last September, I believe you received some samples of water from Dr. Collingridge?—I had 20 samples of water that were forwarded to me by Dr. Collingridge.

10,703. They were all fully labelled?—Yes, they were all fully labelled, and they were labelled as having been collected upon the 14th of September. They were divided into two sections, as it were, one section of the samples being collected at high and low water respectively, and the other near the surface and near the bottom at the different stations.

10,704. At what stations?—The stations were Teddington, Chiswick, St. Paul's Pier, Deptford, and Barking.

10,705. I believe you analysed them, did you not?—I did.

10,706. And your analysis appear upon one of those tables. I think you may as well point out which it is. (*The tables and diagrams referred to in this evidence are those in Appendix A.G. put in by Dr. Tidy.*)

10,707. I believe you conducted your analysis independently of Dr. Tidy; he had other samples handed him?—Dr. Tidy had a similar set of samples for stations lower down the river.

10,708. Some were sent on the same date to Professor Way, and you have seen his results, I believe?—Yes, and also the results of Dr. Tidy's examination of the water at the lower stations.

10,709. Before we deal with this table, you also received some samples, did you not, upon the 26th of September which had been collected upon the 22nd?—Yes, I received them upon the 26th.

10,710. Those samples were taken at neap tide?—Yes.

10,711. And they were taken at Teddington, Chiswick, St. Paul's Pier, Deptford, and North Woolwich? Yes. The diagrams represent the result of the tables.

10,712. (*Dr. Stevenson.*) Is the "nitrates" in the last column nitrogen as nitrates?—Yes.

10,713. (*Mr. Lumley Smith.*) The table, No. 11, at the bottom, contains analyses of water taken upon the 14th of September at the five places you have mentioned from Teddington to Barking?—Yes.

10,714. The next table is a similar analysis for September the 22nd, but taking North Woolwich instead of Barking?—Yes; that is Table No. 12 at the bottom.

10,715. Now, with regard to the one which is numbered 13 at the bottom, what does that represent?—The third table of analytical results refers to samples taken at one station only, viz., at St. Paul's Pier, on different days, showing the condition of the river at that particular station on those days.

10,716. That represents, does it not, analysis taken every day from October the 28th to November the 11th, at St. Paul's Pier?—That is so. These are all the analytical tables. Then comes the diagrammatic representation of the first two tables.

10,717. Would you describe the first of the diagrams which you have handed in; first of all, what is it headed?—The first diagram is headed "Analysis of "water taken at mid-stream at different places on "September the 14th, 1882."

10,718. That is Table No. 11?—Yes.

10,719. Now, what is the next?—The second table is No. 12, "Analysis of water taken at mid-stream at "different places on September the 22nd 1882."

(*Chairman.*) Am I right in understanding that the Table No. 11 put in by Dr. Tidy was the result of his own independent analysis?

*Dr. Tidy* stated that that table was Dr. Frankland's.

10,720. (*Mr. Lumley Smith.*) The next, from Teddington to North Woolwich, September the 22nd, is yours?—It is.

10,721. Now the third?—The third is headed "Results of analysis expressed in parts per 100,000, "collected at St. Paul's Pier;" that is paged 16 at the bottom of the table.

10,722. Now what is the next?—Those are all the tables.

10,723. Now you have some diagrams, have you not?—Yes. The first diagram is called Diagram B.

10,724. What does that show?—That shows, in the upper half, the ratio of nitrogen to carbon in various samples collected at high and low water, at the places indicated upon the diagram on September the 14th, 1882. The second half of the same diagram, the lower half, represents the same thing in connexion with the second set of samples, those collected on September the 22nd, 1882.

10,725. Those are represented in curves from Teddington to Southend?—Yes; therefore they represent Dr. Tidy's samples as well as my own.

10,726. Your tables are based on your own analysis, but this diagram is based upon the combined tables and results of Dr. Tidy and yourself at different parts of the river?—Yes, that is so.

10,727. (*Dr. Stevenson.*) All your results throughout are expressed, not in grains per gallon, but in parts per 100,000?—I think that is so. In using the tables I have made some calculations in connexion with the inquiry in grains per gallon; but all the results in the tables now under consideration are in parts per 100,000.

10,728. (*Mr. Lumley Smith.*) I think you have also analysed the chlorine?—I have one diagram that would come before the chlorine. Diagram C. relates to the samples taken at St. Paul's Pier and at Erith upon the same days. The St. Paul's Pier samples were analysed by me, and the Erith samples by Dr. Tidy. The analyses made by me I have already handed in. These are two diagrams, representing the total carbon and nitrogen at St. Paul's Pier and Erith upon the same day, and the volume of water passing Teddington Weir upon the pays indicated. Now come the chlorine determinations. The chlorine determinations I have only put together recently, and they are not yet printed.

10,729. Now with regard to these tables, first of all are there any general observations which you want to make upon the river before we come to the details?—From the analytical results I have now been putting in, I draw the following conclusions, that in spring tides sea water makes its way up the river as far as Chiswick, but does not reach Teddington; and that wherever sea water is found there is evidence of the presence of sewage in the increased proportion of ammonia and of nitrogen in the dissolved organic matter.

10,730. Dr. Tidy attached a great deal of importance to the presence of ammonia as evidencing sewage; do you agree in that opinion?—Yes. I attach great importance to ammonia in that way; but unfortunately ammonia is a very evanescent substance which rapidly disappears from the samples after they are collected. When it is found it affords indubitable evidence of the presence of sewage, and of a certain amount of sewage; but there may have been a great deal more sewage there than is now apparent, on account of the ammonia having disappeared.

10,731. On its journey from the river to the laboratory?—Yes.

10,732. So that we may take the sewage results from ammonia as the minimum?—As the minimum.

10,733. Of ammonia there is very little or next to nothing in the Teddington water?—Very little indeed.

10,734. Is that also the case in sea water?—Yes, it is also the case in sea water; practically there is none in sea water.

10,735. Then if ammonia is found in the Thames, are there any sources from which it would come other than sewage?—There are no sources of importance;

*Dr. E. Frankland, Ph.D.,D.C.L., M.D., F.R.S.*

28 Feb. 1883.

there are certain discharges into the Thames which do contain ammonia; there is the Beckton Gas Works, for instance, but the amount from that source is, I should say, a vanishing quantity.

10,736. Now with regard to the nitrogen, you spoke of the increased proportion of ammonia and nitrogen; how does nitrogen give you information?—In those samples, from which sea water is practically excluded, the increase in the proportion of nitrogen to carbon indicates the presence of sewage matter; but that evidence cannot be trusted where sea water mixes with the polluted river water, because sea water contains organic matter which is highly nitrogenous, even more highly nitrogenous than that in sewage.

10,737. The nitrogen which you get in the water above the reach of the sea, would be evidence of sewage; but where you get down to the action of the sea water, it may be due to sea water?—Yes.

10,738. What is the next proposition that you lay down?—The character of the suspended organic matter varies very irregularly in different parts of the river; it is sometimes chiefly animal and sometimes chiefly vegetable, as indicated by the proportion of nitrogen to carbon contained in it. And in connexion with this irregularity it is worthy of note that a large proportion of the suspended matter in sewage is vegetable, although nearly the whole of the dissolved organic matter is animal, being the constituents of urine.

10,739. Is the dissolved organic matter a constituent of urine?—Yes, mainly; and it was shown in the Report of the Rivers Pollution Commission with respect to this dissolved organic matter, that it makes a stream much fouler by its discharge than is the case with the suspended matter.

10,740. Can you give us the reference to the evidence or the Report of the Rivers Pollution Commission?—It is the first Report of the Rivers Pollution Commission of 1868. I cannot at the moment give you the page.

10,741. May we take it as your opinion that the river is made more foul by the urine than in the fæces?—Yes, that has always been my opinion since I was a member of that Commission.

10,742. Although it is not so patent to the eye?—No, the eye very often deceives. People think that because water is clear and free from suspended matter it is therefore pure; that is by no means always the case. This is the Rivers Pollution Commission Report on Lancashire.

10,743. (*Chairman.*) Have you any other general results to state?—No.

10,744. You have now stated them. You were asked the question. what were the general results you drew.

(*Mr. Lumley Smith.*) There is yet another which is rather general, and we would rather leave that till we meet on the next occasion.

Adjourned to Tuesday next at half-past 12 o'clock.

---

# TWENTY-SEVENTH DAY.

## Tuesday, 6th March 1883.

PRESENT:

SIR P. BENSON MAXWELL IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, Esq., F.R.S., *Secretary.*

DR. EDWARD FRANKLAND, called again and further examined.

6 March 1883.

10,745. (*Mr. Balfour Browne.*) I think upon the last occasion you promised to give the Commission the page in the Rivers Pollution Commission Report to which you had been referring?—I did; it is page 27 in the first report of Sir William Denison's Rivers Pollution Commission.

10,746. I think, in answer to my learned friend Mr. Lumley Smith, you had given the general conclusions at which you had arrived?—I had given some of them, but I was in the midst of them when the Commission adjourned.

10,747. First, I will ask you with regard to dissolved organic matter in ordinary river water, what have you to say with regard to that?—The dissolved organic matter in ordinary river water is non-putrescible, and contains an average proportion of nitrogen to carbon of 1 to 7, whilst the dissolved organic matter of sewage averages nitrogen to carbon equal to 1 to 2, in sea water the ratio is as 1 to $1\frac{3}{4}$; therefore in a mixture of sea and river water with sewage it is obviously impossible to tell from the ratio of the nitrogen to carbon alone, whether the highly nitrogenised organic matter is derived from sea water or from sewage. It is here that the importance of the ammonia determination comes in, and the ratio between the organic nitrogen and the ammonia, for in sea water the ratio of ammonia to organic nitrogen is only as 1 to 27, whilst in sewage the average is as 1 to 3,

10,748. But we have heard that ammonia is very evanescent; does that qualify what you have said with regard to the value of the ammonia test?—Yes, it qualifies it in one direction, as I think I mentioned upon the last occasion. Where you find this excess of ammonia, it is positive evidence of the presence of sewage; but, if you do not find ammonia, it is not positive evidence of the absence of sewage, the ammonia is evanescent, it rapidly disappears.

10,749. I suppose you have taken the presence of sea water as depending for proof upon the presence or absence of chlorine?—Yes; that is a proof of the presence or absence of sea water. But that there were many samples collected where there was little or no sea water in the river, is evidenced by the low proportion of chlorine in these samples.

10,750. Have you the analyses of any samples in which there was very little chlorine found, to lay before the Commission?—Yes, the tables are already before the Commission. At low water it will be found that at St. Paul's Pier, upon September the 14th, the ratio of the nitrogen to the carbon in the top sample was as 1 to 3·1, and in the bottom sample as 1 to 3·6.

10,751. (*Mr. Bidder.*) What table is that to which you are now referring?—That is the table numbered 11 at the bottom.

10,752. (*Mr. Balfour Browne.*) Have you upon the same table shown a similar result with regard to Deptford?—Yes; at Deptford upon the same day the

ratio was as 1 to 3·2 on the top and 1 to 4·9 in the sample taken 18 feet below the surface.

10,753. (*Sir John Coode.*) I see that in the low water samples there is a difference of a quarter of an hour between the periods at which they were taken, one is at 10 and the other is at 10.15, so that that is hardly a measure of the ratio, is it?—There would be a current at St. Paul's Pier, certainly, but I do not think that would affect the ratio much; of course as the samples were taken by one party, it was impossible to take them exactly at the same moment, but they might have been taken quicker, no doubt, than with 15 minutes intervals. The high water samples undoubtedly were taken at the same moment. Then with regard to those samples I would remark that the proportions of chlorine were only 4·06 in 100,000 parts at St. Paul's Pier, and 48·9 in 100,000 parts at Deptford, both being the proportions at low water.

10,754. (*Mr. Bidder.*) That is not upon the table, is it?—No, that is not upon the table, but that I have got from Professor Way's results, which are already in evidence.

10,755. (*Mr. Balfour Browne.*) Do I understand you to say that it is on account of the small proportion of chlorine that the ratio of nitrogen to carbon becomes of importance?—Yes, it does, because here there is no question of the admixture of sea water to any appreciable extent.

10,756. Now will you take low water at North Woolwich?—At low water at North Woolwich, upon September the 22nd, the proportion of nitrogen to carbon in the top sample was as 1 to 2·5, and in that sample taken 20 feet below the surface it was as 1 to 2·3, although the proportion of chlorine showed only a small admixture of sea water, namely, 8·3 per cent., which is practically nothing as affecting this ratio.

10,757. Have you given the chlorine upon these occasions?—I have said, at all events, that there was an admixture of sea water to the extent of 8·3 per cent., as indicated by the chlorine.

10,758. (*Dr. de Chaumont.*) In both samples?—Yes, they were both alike.

10,759. (*Mr. Balfour Browne.*) Did you apply the same standard to the samples taken at St. Paul's Pier from October 28th to November the 11th?—Yes, and these samples are very interesting, because they show what a very different condition of the river prevails at different times.

10,760. Which table are you now referring to?—I I believe it is on page 16. That gives the samples taken at St. Paul's Pier from October the 28th to November the 11th.

10,761. Do these analyses show that upon those occasions the river was almost absolutely free from sewage at that part?—They do; there was no appreciable evidence of sewage upon that occasion, that is to say, all the time from October the 28th to November the 11th that was the case.

10,762. Does the flow over Teddington Weir, to your mind, account for the analyses that you have upon that table?—Yes it does.

10,763. What was the flow then?—The gaugings show that 5,772,000,000 gallons passed on the average each day over the weir during that time. Now the average flow of the Thames is only 800,000,000 gallons, therefore the quantity of water passing down the Thames during that period was, on the average, seven times as great as the normal flow.

10,764. (*Dr. Stevenson.*) Is the ·046 as the quantity of ammonia, a misprint in the last column but one?—The figures ·046 are correct.

10,765. (*Mr. Balfour Browne.*) I think you have stated that the ammonia test is a good affirmative standard, but not trustworthy as a negative one?—That is my opinion of it.

10,766. Judged by that standard, can you say whether sewage was present in the river above the northern outfall, say, at Blackfriars Bridge on July the 11th, 1882?—Yes, I find, judged by that standard, undoubted evidence of sewage at Blackfriars Bridge upon that date, and also in a sample collected in a line with the Monument on June the 21st, 1882.

10,767. Are those upon the tables?—No, those are the results deduced from the tables; now I found it, as I say, in a line with the Monument upon the 21st of June; at Charlton, Ballast Wharf, Charlton Pier, at Woolwich, 200 yards below the entrance to the Royal Albert Dock, and a little below the Clock Tower, Beckton, upon June the 20th, 1882, again in a very large quantity at the last named station upon July the 11th; the proportion of ammonia in this sample, as will be seen from the table, being no less than 3·28 grains per gallon.

10,768. (*Sir John Coode.*) Is that in the table?—Yes, in the table of results, but not the deductions as to sewage. Those are my own deductions from the ammonia.

10,769. (*Mr. Bidder.*) I think you will find that the materials for the evidence that you are now giving are in Dr. Tidy's table, No. 11?—Yes, that is so.

*The witness explained to the Commission which tables were attributable to himself.*

(*Chairman.*) We may take it from Dr. Frankland that the pages numbered 11, 12, and 16 at the bottom are Dr. Frankland's own. The rest are Dr. Tidy's, with the single exception that some of the diagrams were drawn by Dr. Tidy, and in drawing them he had the assistance of Dr. Frankland.

10,770. (*Mr. Balfour Browne.*) You have spoken of the presence of sewage at various places at certain dates, and the last you mentioned was at the Clock Tower, Beckton, on June 20th, 1882?—Yes, that was about 550 yards above the northern sewer outfall, and upon the same side of the river.

10,771. Then you say again, I think, that at the same station, upon July 11th, the proportion of ammonia in this sample was very large?—Yes, I stated that it was 3·28 grains per gallon.

10,772. What is the proportion in unmixed London sewage?—It varies from 1·711 to 6·527 grains per gallon, and averages 3·013 grains per gallon.

10,773. So that upon this particular day you found a little more than the average in that sample?—Yes.

10,774. (*Chairman.*) Is that in a gallon?—Yes, of the water taken from the river, not from the sewers.

10,775. (*Mr. Balfour Browne.*) This is a sample taken from the river opposite the Clock Tower at Beckton. How far is the Clock Tower at Beckton above the northern outfall of the Metropolitan Board of Works?—About 550 yards.

10,776. Have you any opinion as to how or why that amount of ammonia came to be in that sample upon that particular day?—I imagine there was a stream of sewage flowing from the northern outfall and following the bank up the river at that time, so that the sewage with but a slight admixture of river water was on this occasion taken as a sample. That is my opinion about it.

10,777. Now at Chiswick, upon the 14th of September 1882, does your analysis show a very high proportion of ammonia?—Not a very high proportion, but an abnormally high proportion.

10,778. What table is that in?—The table of September the 14th is the first table I produced, that is to say, Table 10 on page 11.

10,779. Does that indicate to your mind any admixture of sewage?—Yes, it does, a slight admixture of sewage. Again, upon the same day, sewage was unmistakeably present at St. Paul's Pier.

10,780. That is shown upon the same table?—Yes, the table relating to Deptford and North Woolwich. North Woolwich is on Table 9, page 10.

10,781. That is upon the table for which Dr. Tidy is responsible?—Yes. Then upon the 22nd of September sewage in very appreciable amount was present in the Thames at Deptford and North Woolwich.

10,782. Those are upon your own two tables at pages 11 and 12?—Those are upon pages 12 and 13, page 12 being mine and page 13 Dr. Tidy's.

*Dr. E. Frankland.*

6 March 1883.

10,783. Is there not ammonia present in Teddington water?—Yes, but it is under 0·02 parts in 100,000.

10,784. Have you in all these analyses corrected for the Teddington proportion of ammonia?—I have. In the samples collected at North Woolwich on the 22nd of September the proportion of ammonia, after deducting that found at Teddington, was ·199 of a grain per gallon at one foot below the surface, and ·109 of a grain per gallon at 20 feet below the surface.

10,785. The first figure you gave was at one foot below the surface?—Yes.

10,786. North Woolwich is given on Table 11, page 12?—Yes.

10,787. You give as the average proportion of ammonia in London sewage 3·013 grains per gallon?—Yes.

10,788. (*Sir John Coode.*) That is taken from the sewer?—Yes, the average of 21 samples taken from a large London sewer. Then, taking the average quantity of ammonia in the London sewage as the basis of calculation, the numbers I have just given correspond to 6·61 gallons of sewage in each 100 gallons of Thames water at the surface, and 3·58 gallons of sewage in each 100 gallons of water 20 feet below the surface.

10,789. (*Mr. Bidder.*) Does that refer to the 22nd of September figure at North Woolwich?—Yes.

10,790. (*Mr. Balfour Browne.*) All these results ought in a sense, of course they cannot be corrected arithmetically, but they ought to be corrected practically by the fact that the ammonia is passing away, and that, therefore, these results are below the actual amount?—It is almost impossible to get the samples to the laboratory and analysed before a considerable proportion of the ammonia has disappeared.

10,791. Would you say that these amounts of sewage arrived at in the way you have stated indicate a serious pollution of the Thames?—Yes, I consider that these proportions of sewage are very serious indeed as being present at that portion of the river.

10,792. Upon August 16th you made, did you not, an analysis of water taken on that day?—That analysis was made by Dr. Tidy.

10,793. It was at All Hallow's Pier that the water was taken?—Yes, and there was an appreciable percentage of sewage upon that occasion.

10,794. That was made by Dr. Tidy, and it is on page 15, Table 13, I think?—Yes.

10,795. Again, from October the 28th to November the 11th, that is shown upon your table, page 16, during the period when the river was scoured out by a large quantity of water coming over Teddington Weir; what was the sewage at St. Paul's Pier on that occasion?—Practically nil, though there was abundant evidence of its presence at Erith.

10,796. It was present at Erith, but not at St. Paul's Pier?—Yes.

10,797. By the chlorine table, which I think Professor Way is responsible for, you found out the proportions of sea water at various points?—Yes.

10,798. You have used that table in your various calculations?—Yes, I have.

10,799. And those analyses of Professor Way's show that the sea water gets up the river as high as Chiswick?—Yes, there is evidence of a small quantity of sea water as high as Chiswick.

(*Chairman.*) We had this from Mr. Baldwin Latham.

10,800. (*Mr. Balfour Browne.*) Yes, the chlorine test has been used by every witness. (*To the witness.*) Does the presence of sea water, in connexion with the float experiments, afford evidence of sewage pollution at points very far above the outfalls of the Metropolitan Board of Works?—Certainly, because the sea water cannot obviously get up the river above the outfalls without carrying the sewage with it.

10,801. You are of opinion, are you not, that sea water contains upon the average 1,975·6 parts of chlorine in the 100,000?—I have made very numerous analyses of sea water collected upon our coasts and upon the Atlantic, and those are different in some respects from Dr. Tidy's which were given the other day. My figures come out on the average at 1975·6 parts of chlorine in 100,000 parts.

10,802. (*Sir John Coode.*) You say that you have taken samples from the Atlantic and from our own coasts, do you find any material difference between the two?—The sea water along our own coasts is always a little more dilute than it is in the middle of the Atlantic. The mid-Atlantic samples were not taken by myself; they were taken during the cruise of the "Porcupine."

10,803. We can dispense with them if you will give us those along our own coasts?—At Worthing I have found 1948·5.

10,804. (*Mr. Bidder.*) What are you reading from?—I am reading from the Sixth Report of the Rivers Pollution Commission, page 132. On another occasion I found 1995·6 also at Worthing; and, upon a third occasion, 1996·2; at Hastings I have found 2050; in mid-channel, between Arran and Ardrossan, if that is not too far out of the way, I found 1943·7; at Aberystwith, between the Ystwith and the Rheidol rivers, 1630, that is to say, that out at sea, between those two rivers, where it was, no doubt, diluted by the river water, it was 1630.

10,805. (*Sir John Coode.*) Were those all surface samples?—Yes; they were all surface samples, taken about a mile from the shore.

10,806. How do you account for the very striking difference between the 1948 at Worthing and the 2050 at Hastings; can you account for that?—No, except by the difference between the rainfall from time to time. For instance, such a rainfall as we had last month would make an appreciable difference. Then, in Mount's Bay, Penzance, I found 1987·5.

10,807. There we have no large rivers?—No. At Bridlington, from the end of the pier, January 11th, 1873, 1850 parts per 100,000; at Brighton, from the end of the new pier, on January 18th, 1873, I found 1962·5 parts; at Eastbourne, one mile from the shore, on February 22nd, 1873, the proportion was 1937·5; at Ramsgate, half a mile from the shore, on March 2nd, 1873, 1893·7 parts; at Portland, at the mouth of the harbour, on March the 11th, 1873, the proportion was 2012·5. Those are all samples upon our own coasts.

10,808. What is your general conclusion as to about the normal proportion in the sea in its normal condition at the mouth of the Thames; what would you give as your figure?—I would say it would vary, of course, when there is flood in the river, and when the river is very low; but I would say it would be at high water somewhere about 1900; that is merely a rough figure.

10,809. (*Mr. Balfour Browne.*) The 1975·6 is the average of all the cases you have been quoting to the Commission?—Yes; and also of the samples from the Atlantic; those are also included in the average.

10,810. (*Dr. Stevenson.*) May I ask, does not the chlorine in the sea water away from the shore always bear a definite relation to the total solid matter in the water?—I have not been able to verify that, but I should think it exceedingly likely. For instance, in the sample at Hastings, one hour before high water, the chlorine was rather high, 2050, and the total solid matter was also high, being 3955, whilst, when the chlorine was 1630 at Aberystwith, the total solids were only 3243, so that they obviously follow the same line of reduction and increase.

10,811. (*Mr. Balfour Browne.*) What number of parts of chlorine do you find in London sewage?—I find, in London sewage, a little over 10 parts in 100,000. The average is 10·3.

10,812. In Thames water you have already said what it is?—It is about ·2.

10,813. I think that Professor Way's analysis shows that the proportion of chlorine in all parts of the cross-section of the river is substantially the same?—Yes: and that is a very important thing to establish,

because it enables us, with much confidence, to calculate the proportion of sea water in the river; both at different depths and in different positions across the river it is the same.

10,814. That you have not done for yourself, but you have taken it from Professor Way's analysis?—I have.

10,815. (*Sir John Coode.*) Is that due to chemical affinity in any way, or, how do you account for the ready diffusion of the chlorine?—I think the mixture takes place partly by eddies in the river, and partly by diffusion; where you have two liquids of different specific gravity, there is always diffusion going on between them.

10,816. Do you think there is anything more than mechanical diffusion?—No, I do not think there is; I do not think there is any chemical affinity in the case.

10,817. (*Mr. Balfour Browne.*) You have made, have you not, some experiments which indicate the effect of the upland water in pushing back the sea water?—I have.

10,818. Will you give us those?—The results upon the tables which I have put in show how enormous is this influence of the floods during their continuance in pushing back the sea water. At North Woolwich during high water, for instance, one third of the river was sea water in September, whilst, on November the 30th, at high water, sea water to the extent of only one-fifteenth was present, the variation being from one-third to one-fifteenth.

10,819. Upon that occasion, when it was one-third, there was a small proportion of land water coming over, and when it was one-fifteenth there was a heavy flood?—Yes.

10,820. Have you determined the proportion of sea water in a large number of samples of water taken at various points upon the river?—I have.

10,821. From Teddington to Southend?—Yes.

10,822. These samples were collected upon the 30th of November?—Yes.

10,823. What was the result then?—The result then was that there was no sea water at Teddington, either at low or high water, and that the sea water at Chiswick was inappreciable, both at low and high water: and the same was the case at St. Paul's Pier. At Deptford the sea water was inappreciable at low water, but amounted to ·95 per cent. at high water; at North Woolwich it was inappreciable at low water, and 6·6 per cent. at high water; at Barking it was ·17 at low water, and 8 per cent. at high water; at Crossness it was 8·7 at low water, and 15·3 at high water; at Erith it was 4·3 at low water, and 17 per cent. at high water; at Southend it was 78·1 per cent. at low water, and 90·8 per cent. at high water. There was then a very heavy flood in the river.

10,824. It is upon these figures, as compared with other figures, that you have arrived at the general conclusions you have just stated to the Commission as to the effect of the upland water?—Yes.

10,825. (*Mr. Bidder.*) Let me ask you this question for the purpose of identification: those are deductions, are they not, from the tables already put in?—Those are deductions from Professor Way's tables.

(*Mr. Balfour Browne.*) They were put in by Mr. Baldwin Latham then for now.

(*Chairman.*) You are taking up a great deal of Dr. Frankland's time unnecessarily by making him give the contents of the tables.

(*Mr. Balfour Browne.*) But the witness has drawn the deductions from the tables.

(*Mr. Bidder.*) And those deductions have been given by the engineers.

10,826. (*Mr. Balfour Browne to the witness.*) I think you have given the deductions you have taken from Professor Way's tables?—The deductions are the percentages of sea water which I have calculated from the results of Professor Way's tables.

10,827. (*Chairman.*) Are the figures you have given us taken merely from Professor Way's tables, or, did you yourself analyse them?—I also made some of the analyses.

10,828. Those are your own analyses?—They are partly from my own analyses, and partly from Professor Way's; but the two sets of analyses agree very closely. There is, substantially, no difference between them.

10,829. They are the result of your own analyses then?—Yes.

10,830. (*Mr. Balfour Browne.*) In many cases you did your own analysis?—Yes.

10,831. From those experiments and from the float experiments, is it your view that during a heavy flood the sewage from the main drainage outfalls reaches London?—No, not during heavy floods; it is then carried bodily down.

10,832. But when it is discharged at or near low water, is it your opinion that when the river is low the sewage does reach London, and go above it?—When the flow of the river is normal, and below that, it then reaches London, and, under favourable circumstances, gets as far as Chiswick.

10,833. But, even under normal circumstances, how far would it get up; what part of London would it reach?—I would say it would get to Chelsea, certainly.

10,834. And, having reached there upon one tide, would it oscillate through London for a considerable number of tides?—Yes; I believe it would oscillate for many days, or even weeks, before it was finally carried out to sea.

10,835. Is it your view that the condition of the Thames in the metropolis, that is to say, from Chelsea to the Docks, is becoming worse or better?—I am of opinion that the river is rapidly becoming worse, partly from the greater amount of sewage discharged into it, owing to the increase of population in London, and partly from the accumulation of mud banks, which are increasing under our windows here, and are increasing from year to year; they putrefy in warm weather, and create what we may call a permanent nuisance.

10,836. Is it your view that it will become as bad ——

*Mr. Bidder* objected to the question.

10,837. (*Mr Balfour Browne.*) As bad as it was in the year 1858?—I think it is very likely it will before long.

10,838. (*Sir John Coode.*) Is it progressively worse?—In my opinion it is.

10,839. And not better and worse, according to the floods?—It is that; but I mean taking the average condition of it, it is gradually becoming worse.

10,840. (*Dr. Stevenson.*) Do you think it will become worse, if the amount of sewage thrown in does not increase?—Yes; I think it will even then become worse, on account of the accumulation of these mud-banks; I think they will go on increasing.

10,841. (*Mr. Balfour-Browne.*) When the Metropolitan Board of Works contemplated the present scheme for the disposal of the sewage, I think you were consulted with Dr. Hofmann, as to the deodorization of the sewage before it was turned into the river Thames?—Yes, that is so; that was in the year 1859. We had a great number of schemes of dealing with the sewage at Barking, and Crossness submitted to us at that time by the Metropolitan Board of Works, and we were requested to examine them, and to report which would be the best for the treatment of sewage, before it was discharged into the Thames.

10,842. So that at that time they appear to have contemplated deodorization. Did you report your view?—We did, and we recommended that deodorization should be carried out, especially in the summer, by means of per-chloride of iron.

*Mr. Bidder* objected to this evidence as irrelevant.

10,843. (*Mr. Balfour-Browne,*) However, you recommended deodorization, and that deodorization has not been carried out?—No, that deodorization has not been carried out.

10,844. Upon the last occasion, you mentioned a table, which you had made out, showing the amount

*Dr. E. Frankland.*

6 March 1883.

of suspended matter in London sewage?—I do not think I mentioned it upon the last occasion.

10,845. I think my learned friend, Mr. Lumley Smith, stated that it would be printed by our next meeting, and would then be put in?—That was so.

10,846. Have you that report before you?—I have.

10,847. Will you hand in a copy of it?—I will. (*The witness handed in a "Report on the suspended matter in London sewage." See Appendix AH.*) I may say that this is a very elaborate investigation into the amount of suspended matter discharged into the Thames from the London sewers in 1878 and 1879. I have taken out of the Registrar General's weekly returns the rainfall upon every day during those two years, and making use of all the sewage analyses which are available, many of them having been made by the late Mr. Keats, the chemist to the Metropolitan Board of Works, I have taken out the volume of sewage, and the percentages of suspended matter, and the total amounts of suspended matter discharged on each day during those two years. Then there is, at the end of this report, a summary, showing the aggregate quantity of mud discharged into the Thames during those two years; and this works out to 505,257½ tons of dry mud discharged in the year 1878; and in the year 1879, 541,965·8 tons. Then the quantity of wet mud containing 60 per cent. of water, which is the quantity of water determined, in the deposits in the Thames, by Dr. Tidy was 1,263,143·65 tons in 1878, and in the year 1879 it was 1,354,914·38 tons. Of course, if the Commission wish, I will go into the details as to the manner in which these numbers are arrived at, but they are all in this report, which, I presume, will be in the hands of the Commissioners.

10,848. Those are the results of your investigations, which you have just stated to the Commission. Now will you give us, first, the amount of dry mud, and, secondly, the amount of tons of wet mud?—Yes. Perhaps I may be allowed to say that I undertook this investigation, which was a very laborious one, from the conviction that little or no notice had been hitherto taken of the discharge of suspended matter during storms; it has been always, as a rule, fair weather sewage, or what Mr. Bidder calls normal sewage, which has been noticed, and I thought that it would be important to notice and ascertain what effect storms would have in increasing this quantity.

10,849. (*Professor Williamson.*) I wish to ask you what is your use of the term "wet mud." I presume it is collected without much drying, but it might be either very wet, or only a little wet; what is your unit?—60 per cent. of water was determined as the average, I think, of a good many samples of mud dredged up from these banks in the Thames near the sewer outfalls.

10,850. And taken as it came up in the dredger?—Yes.

10,851. Was it weighed in the state in which it was brought up?—When the water had run off it was weighed, and then dried; I take it as dry at the temperature of boiling water.

10,852. (*Chairman.*) It would vary, I suppose, according to the specific character of the mud?—Yes, a little; but I have given the dry mud, so that it can be taken in that way as well. These tables also show that when these enormous quantities of suspended matter are brought down by storms the proportion of mineral matter is very much increased, so that the mud is much less polluting than it is in fair weather.

10,853. (*Professor Williamson.*) Is it absolutely less?—No, not absolutely less, but relatively less; the absolute amount of mud is much greater.

10,854. It is not all organic mud, but some of it is inorganic?—It is a mixture of organic and inorganic mud.

10,855. What is the meaning of the tables on page 18 being ruled through with red ink, is it that they are not correct?—They are ruled through, first of all, because they indicate an abnormally large percentage of suspended matter, there is something abnormal about them.

10,856. (*Chairman.*) They ought rather to have been underlined, ought they not?—The object is to place the whole evidence before the Commission, therefore they are ruled through, they are eliminated, they are not intended to be taken as part of the average.

10,857. (*Sir John Coode.*) They are all exceptionally large, I see?—Yes, they are all exceptionally large; that is, therefore, in favour of the non-pollution of the Thames. I did not take these figures, lest it should be said that they were not taken fairly. Those marked with one asterisk are from the analyses of Messrs. Hofmann and Witt, which are published in the Blue Book; that is all explained in the report. You will see one reason for ruling out, upon April the 8th, "rain previous afternoon," which no doubt affected that sample, and that is ruled out as being abnormally high.

(*Sir John Coode to Mr. Balfour-Browne.*) I think it would be very desirable if you could give us, in future, these figures, all referring to one common standard, whether grains, or parts per 100,000, as far as you can.

*Mr. Balfour-Browne* stated that he would have that done in future.

10,858. (*Mr. Balfour-Browne to the witness.*) I see in this report that each table is described on page 2?—Yes.

10,859. Now I want to direct your attention to the question of oxidation. Dr. Tidy, when he was in the chair, I think, said that he had very often appeared upon a different side from yourself on this matter of oxidation, and getting rid of sewage by means of it.

10,860. (*Mr. Bidder.*) The point upon which they differed was rather the getting rid of the germs.

10,861. (*Mr. Balfour-Browne.*) Is sewage matter got rid of, in your opinion, slowly, or rapidly, by oxidation in running water?—It is got rid of very slowly.

10,862. You have, I think, made careful and repeated experiments upon the River Irwell?—Yes, I have on the River Irwell, just below Manchester, and before its debouchment into the Mersey, which takes place above Warrington.

10,863. I think you examined it from Throstle Nest Weir, which is just below Manchester, and below all the sewer outfalls and all the factories?—I took samples there, and again 11 miles lower down the river, just before it joins the Mersey, and compared those samples with each other; they were taken upon the same day, and time was allowed for the river to flow from one place to the other, as nearly as I could guess; of course, that was a guess.

10,864. (*Sir John Coode.*) What was the distance?—The distance was about 11 miles.

10,865. And the time?—I forget how much time we allowed for it; I think about 8 or 10 hours was allowed for the flow. I may say that the river, upon its way between those two points, falls over six weirs, a total height of 34½ feet; this fall covers the water with foam for hundreds of yards below each weir, so that it gets very well aërated at each of those weirs.

10,866. (*Mr. Balfour Browne.*) Each of those weirs affords a chance of good oxidation?—Yes.

10,867. What was the result of that 11 miles run?—The purification from suspended matter by subsidence was very considerable, varying from 9 per cent. of the total suspended matter up to as much as 48·6 per cent. deposited upon the road, but the purification from polluting organic matter in solution was much less, and was sometimes even a minus quantity, that is to say, there was no improvement whatever, but apparently, a deterioration, which was due apparently to precisely the same water not being taken in the two places.

10,868. Have you a short statement, which you can give, of your determinations?—I have. In the first determination there was a diminution in the polluting matter in solution of 1·7 per cent. in that flow; in the second determination there was an increase of 7·9 in the polluting matter in solution;

upon the third occasion (these were made upon three different days and at three different times of the year) there was a diminution of 26·6 per cent.

10,869. (*Sir John Coode.*) Are there any tributaries between the two points?—There are practically no tributaries between the two points. There are very few places in England so well fitted for such experiments. I know of only three, and I have made an experiment at each of those places, but this River Irwell more closely resembles the case of the Thames so I have selected it.

10,870. (*Professor Williamson.*) Was the temperature to any extent different between the dates of making those determinations?—It was. When the greater purification took place the temperature was higher.

10,871. (*Dr. Stevenson.*) Was the water examined for organisms?—No, there may have been organisms there, but there is no vegetation in this section of the river at all; it is too polluted for that.

10,872. Do you find that the power of self-purification of a river depends upon what are called micro-organisms in it?—Yes.

10,873. And does not a certain quantity of impurity prevent the existence of those organisms?—I do not know that. I think that what we may call the putrefactive bacteria get on pretty well in any sort of liquid.

10,874. You would not agree with the statement that the occurrence of these living organisms depends entirely upon the temperature of the medium?—No, I would not agree with that; upon the first occasion, that is, when the purification amounted to 1·7 per cent., the temperature was 6·2 Centigrade; when it amounted to 26·6 per cent., the temperature was 17·8 Centigrade.

10,875. (*Mr. Balfour Browne.*) Dr. Tidy compared the pollution of the Irwell below Manchester with the river flowing through Warrington?—Yes, and there he fell into a slight, or perhaps more than a slight, error, because the River Irwell does not flow through Warrington.

*Mr. Bidder* objected to the evidence on the ground that it was not usual to call one witness to rebut the evidence given by another upon the same side.

*The Chairman* ruled that the evidence was admissible.

(*Witness.*) I wished simply to explain the cause of the apparent discrepancy between Dr. Tidy's statement and my own; he says he examined the Irwell at Manchester, and again at Warrington; now, the Irwell falls into the Mersey 3 miles above Warrington.

10,876. (*Mr. Balfour Browne.*) Is the Mersey a much less polluted river than the Irwell?—Yes, much less.

10,877. Have you made experiments upon London sewage with the view of ascertaining, in the laboratory, the amount of oxidation that goes on?—Yes, I have mixed one volume of filtered London sewage with nine volumes of fresh water. I freely exposed the mixture to light and air, and then I syphoned the mixture over from one vessel to another every day, allowing it to fall in drops from one vessel to the other, so as to give it thorough aëration. I may say that it fell a distance of three feet from one vessel to the other. I found that after 96 hours the organic polluting matter of this mixture had only been reduced by 11·5 per cent.; and after 192 hours the reduction was only 27 per cent. That was the result of these experiments upon the mixture of London sewage with fresh water.

10,878. Does that result bear out your conclusion that oxidation takes place very slowly in running water?—Yes, it does. I assume that a river runs at not a less speed than an average of a mile an hour, and I say that the result of the experiment is that after 192 miles run such a mixture of sewage and water would not, from oxidation alone, at all events, have its impurity reduced by more than 27 per cent.

10,879. In the last answer you said that you did it with filtered London sewage?—Yes.

10,880. But that filtration, I presume, did not vitiate the experiment at all, because all the organic matter was in the sewage?—Yes, it was still polluted with the organic matter; but I filtered it, because the suspended matter would have introduced a difficulty into the analysis.

10,881. Did you also mix a certain proportion of urine with a quantity of deep chalk well water?—I mixed them in the proportion of one gallon of urine to 3,077 gallons of deep chalk well water; this mixture was exposed to the air, briskly agitated, and then syphoned over from one vessel to the other, as in the previous case. Samples were taken for analysis, from time to time, so as to ascertain what was going on; the mixture being first submitted to analysis before the oxidation began. The results of these analyses show that urine, when mixed even with enormous volumes of water, is under atmospheric influences very slowly oxidised. Flowing at the rate of only one mile an hour in a river, the mixture experimented on would travel over 264 miles before it would lose, by oxidation, seven per cent. of its polluting constituents.

10,882. Have you confirmed the result of these experiments by ascertaining the rate at which dissolved oxygen disappears in a mixture of the Grand Junction Company's Thames water and sewage?—Yes; I mixed the Grand Junction Company's water with five per cent. of fresh London sewage, and immediately after the mixture the proportions of organic carbon, organic nitrogen, and dissolved oxygen, and also dissolved carbonic acid, were carefully determined. Then the mixture was put into a number of carefully stoppered bottles which were exactly filled with it, so that no air could gain admission. One of those was opened every day, and the amount of dissolved oxygen and of carbonic acid was determined every 24 hours, except upon the occasion of an intervening Sunday, when 48 hours elapsed between two determinations.

10,883. (*Sir John Coode.*) For how many days?—That was carried on for six days.

10,884. (*Mr. Balfour Browne.*) Are those figures that you are going to give upon the supposition that the oxygen disappeared every day by being used up by the organic matter of the sewage?—Yes, I am going to assume that all the oxygen that had then disappeared was used up in oxidising it, and converting it into carbonic acid, water, and free nitrogen—that is entirely upon an assumption which I am going to tell you cannot be the case here; but, assuming the oxygen was doing its work in the way of burning up the sewage, as has been mentioned before, then in the first period of 24 hours 6·8 per cent. of the sewage would be destroyed, and in the second period of 24 hours 8·9 per cent. of sewage would be destroyed.

10,885. (*Sir John Coode.*) Do you mean in addition?—Yes, in addition. Then in the third period of 48 hours, that was the one with the Sunday intervening, 14·3 per cent. would be destroyed.

10,886. Also in addition?—Yes, all these figures are additional. Then in the fourth period of 24 hours 5·4 per cent. would have been destroyed; in the fifth period of 24 hours 5·8 per cent. would have been destroyed; and in the sixth period of 24 hours 2·1 per cent. would have been destroyed.

10,887. (*Dr. Stevenson.*) Could you give the Commission the amount of oxygen which disappeared in the first 24 hours?—Yes, you have it all in the sixth Report of the Rivers Pollution Commission, page 138; in the first 24 hours ·803 was the weight of oxygen which was left after 24 hours, so that what had disappeared was the difference between ·946 and ·803.

10,888. That is about 15 per cent.?—I presume it would be. I am not very rapid at mental arithmetic. The other weights are all given at page 138 of the sixth Report of Sir William Denison's Rivers Pollution Commission.

10,889. (*Mr. Balfour Browne.*) You said that you

*Dr. E. Frankland.*

6 March 1883.

would explain further as to the oxygen not being entirely used in the destruction of sewage, will you now do so?—Yes; these numbers I have been giving are upon the assumption that the oxygen was doing its work simply in the way of destroying the sewage; but, as a matter of fact, there was no sewage whatever destroyed during this time, because, if the sewage had been so burnt up, then the proportion of carbonic acid found in those bottles would have increased, whereas it remained exactly the same during the whole time; so that no sewage whatever was burnt up during the time; it was only oxidised into more highly oxygenous compounds.

10,890. So that in one sense that ·803 destruction of sewage gives quite an erroneous notion of what took place?—Yes, it is merely adopting that assumption which, as I have said, is quite an absurd assumption under the circumstances.

10,891. You have given us the results of the examination of the river Irwell at various points of its flow, and found out the rate at which sewage disappeared in that river, and then you have performed the experiment with a mixture of sewage and urine, and you have found out that the rate of disappearance is exceedingly slow in those cases?—I have; and I say that it is impossible for us, taking those experiments as our guide, to say how far water so contaminated must flow before the sewage has become oxidised and converted into inorganic compounds.

10,892. Is that the case even when the sewage is mixed with large volumes of pure water?—Yes.

10,893. I see that upon this diagram A., which was put in by Dr. Tidy, two red lines have been drawn by you, will you explain them?—They show the same things relative to samples taken by himself and taken by myself. The samples were not taken under the same conditions of time, therefore I thought it worth while to draw out the curves showing the result of my own analysis, and they are as represented by these red lines; they tell the same story, but in a somewhat milder form. The river was presumably rather more in flood at this time; it was later in the season when my samples were taken.

10,894. What date was that?—These lines refer to the dates of September the 14th and September the 22nd.

10,895. Those lines represent the mean, I think, between aboslute high water and absolute low water?—They do. Each index point in these curves is the average of four analyses; two of the samples were taken at high water near the top and near the bottom, and two at low water near the top and near the bottom; one line represents spring tides, and the other neap tides, the upper line being the spring tide line.

10,896. And by putting on these lines, does that in your opinion confirm the accuracy of the results of Dr. Tidy's table?—It does; we have the same rise in them of organic impurity, at the same places they rise in the same way, but not so high.

10,897. (*Sir John Coode.*) Is not there rather a discrepancy between the red and black lines upon the top left-hand side of the table. There is a general agreement until you get near the end, and then there appears to be a falling off in your red line?—I think that is probably owing to the much larger number of samples which were examined by Dr. Tidy. This line falls from that line to there (*pointing to the diagram*), because there was no sample analysed between those two points; my red line represent only my own samples. There is an interesting thing here with regard to the organic nitrogen which shows that the organic nitrogen and the organic carbon almost meet at Southend, owing to the increased organic nitrogen in the sea water.

10,898. (*Dr. Stevenson.*) Have you any experiments in support of the conclusion that putrescible matter oxidising in water will eventually give rise to bodies containing as large a per-centage of nitrogen as carbon?—No, I have no experiment showing that.

(*Mr. Balfour Browne.*) If you draw a line from 47 to the bottom of 58, you will find that the two lines are exactly identical.

(*Sir John Coode.*) That bears out what Dr. Frankland told us, that, if he had had intermediate observations, his line would have corresponded with Dr. Tidy's line.

(*Mr. Bidder.*) In point of fact, the red line after a certain point is hypothetical altogether.

10,899. (*Mr. Balfour Browne to the witness.*) Now I will ask you one general question. You have spoken of the oxidation that takes place in the flow of the river; would oxidation take place more rapidly in a tidal river, such as at Barking and Crossness, than in a river which was non-tidal, flowing over stones and weirs?—Upon that point I can only give you my opinion gathered from my general study and experience. I have no definite observations upon the subject, but I should say that oxidation would be likely to take place more slowly in such a tidal river as the Thames than in a non-tidal river.

10,900. (*Professor Williamson.*) Have you any experience of the effect of the presence of salt upon the process of oxidation when sewage is present, whether it increases or diminishes the rate of it?—I have no experience in that respect.

Cross-examined by Mr. BIDDER.

10,901. You say very frankly that you have no definite observation which would enable you to say with confidence that the process of oxidation does go on more slowly in a tidal than in a non-tidal river?—No, I have no experimental determinations upon which to form a trustworthy judgment.

10,902. With regard to the figure you gave to the Commission in support of your opinion that oxidation goes on more slowly even in a non-tidal river than Dr. Tidy thought, I shall not be wrong if I say that you and Dr. Tidy have come to a diametrically opposite conclusion upon that point?—Upon the point of absolute quickness and slowness we are opposed, but we do not differ fundamentally upon the fact.

10,903. Dr. Tidy says that, if you put sewage into an unpolluted river, a run of 14 miles will destroy it, but your evidence goes to show that 20 times that run will not destroy it?—Yes.

10,904. Your evidence being founded upon the tables which are given in the Rivers Pollution Commission Report?—Yes.

10,905. Now I will ask you this: Is it quite certain that the laboratory experiment of water kept in a bottle and syphoned off to another bottle is quite the same as water running in a tidal river over a rocky or sandy bottom?—As far as oxidation is concerned, it is quite the same, I think.

10,906. You are aware, I presume, of the experiments made by Dr. Tidy, in which the results are very different?—I think I explained them.

10,907. You mean that they were not what Dr. Tidy thought they were?—I think he was mistaken in the conclusions he drew from the experiment. That is what I said upon the last occasion. You are referring, I think, to the experiments upon the River Shannon?

10,908. No, I am not. I am referring to the experiment recorded at the end of his pamphlet, conducted by himself, by mixing certain proportions of sewage and river water, letting it run a certain distance along troughs, and analysing it before and after the experiment?—Yes; those are laboratory experiments.

10,909. I will take one for illustration from page 44 of his pamphlet. "River water contained 4 per cent. "of sewage; the time and travel occupied a distance "of 1 mile in 8 hours; result, that of the oxygen "required to oxidise the organic matter before the "experiment, 2·80 of a grain, 1·9, or more than "2/3rds, had disappeared in the process." Does

not that experiment show, if such a result is obtained, that 2/3rds of the organic matter had disappeared in the course of that experiment?—Yes, if the experimental results are altogether conclusive upon that point; but that did not appear to me at the time to be so. I really forget now the objection I raised to those experiments at the time, but it is recorded, I think, in that same journal.

10,910. (*Chairman.*) You differed from that?—Yes.

10,911. (*Mr. Bidder.*) Have you performed that experiment of Dr. Tidy's yourself, and got out a different result?—No, I never performed the experiment which you have described.

10,912. Then how do you mean you differed?—I differed as regards drawing a conclusion from the experiment; and, if I am not mistaken, I think the ground for my demurring to that experiment as conclusive was this: That, first of all, these troughs were out in the London atmosphere, where they were exposed to all kinds of dust and dirt; secondly, that in the gutters of these troughs (because they were V-shaped, if I remember rightly) the suspended matter underwent some sort of putrefaction, at all events it formed the nidus for bacterial life and organisms of that sort, which, no doubt, are very active in destroying sewage matters.

(*Sir John Coode.*) Is that rate of progress right, one mile in eight hours; it seems incredibly slow?

(*Mr. Bidder.*) I believe it is right.

10,913. (*Chairman.*) You mentioned a quantity of sewage matter getting into a V-shaped trough, and so generating bacterial life?—That would induce putrefaction of the sewage, and my experience of sewage and sewage-contaminated water is that such matters purify much more rapidly by putrefaction than by oxidation. They are much more offensive while they are putrefying, but they purify more quickly by putrefaction than by oxidation.

10,914. (*Sir John Coode.*) When you say they are more offensive, do you mean that the gases they would give off would be more injurious?—Yes.

10,915. Not simply more offensive, but actually more injurious?—Yes, because the gases are mixed with sulphuretted hydrogen usually during putrefaction.

10,916. (*Mr. Bidder.*) If I follow you, you no doubt accept Dr. Tidy's observation of what resulted, but your explanation of it is that possibly there was London dirt got in, and possibly there was a development of bacterial life?—Yes. There is another point which now occurs to me; if I had known that I should be asked these questions, I would have looked through the papers; that probably the diminution in the organic matter which Dr. Tidy found upon that occasion was due to the decomposition of urea in the fermenting matter which was deposited in the V-shaped gutters.

10,917. We have a hypothetical matter fermenting which has developed in the eight hours of the experiment?—But the experiment lasted much longer than eight hours, I think.

10,918. Perhaps you know better, but all his experiments, he says, were of the duration of about eight hours, from 3 p.m. till 11.30 p.m.?—I was under the impression that his experiments were continued the next day.

10,919. Will you see for yourself (*handing the pamphlet to the witness*)?—You are right.

10,920. So that the time is rather short for the fermentation and development of bacterial life?—A good deal may be done in eight hours in the way of propagating bacteria.

10,921. We have not only got to develop them, but we have got to get their action upon the sewage. Now that leads me to ask you another question. Is it not the case that in a river, where sewage is mixed with large quantities of river water, there is a great development of living organisms which play a very important part in dealing with the sewage elements?—Yes, I should say that is very probable, although I am not personally familiar with the subject.

10,922. Have you made any observations with a view of ascertaining to what extent the living agencies in the case of a river like the Thames operate?—I have made observations in the unpolluted portions of the Thames itself, where all these things which you are speaking of, I presume, would be in activity, such as plant life, and so on.

10,923. Just let me ask you this: when you as a chemist analyse a sample which somebody has brought to you from a part of the Thames, you ascertain what is organic by distinguishing between the combustible and non-combustible portions, do you not?—Oh dear, no. I burn the residue of the sample, and determine the weight of the carbon and of the nitrogen in the organic matter.

10,924. Perhaps I put my question clumsily; your chemical analysis does not distinguish between dead and living organic matter?—No.

10,925. So that, in point of fact, what you are recording in your analyses as organic pollution may be, as far as your chemical analysis goes, your organic scavengers?—Yes, as far as the chemical analysis goes; but I have made a microscopic analysis at the same time. I have examined many samples of Thames water which have been perfectly clear, and have never been able to discover one of these scavengers. When there is a deposit of suspended matter, then, as a rule, you find these organisms in this suspended matter. But surely, if they were present in such large quantities, you would find them in the clear water.

10,926. Let us go step by step, if you please; as far as a chemist is concerned, he has no means of telling from his analysis whether that which he records as organic nitrogen and carbon represents dead polluting matter, or such as I called living organic scavengers?—No.

10,927. Have you made microscopic examinations of the water in that part of the river which we are considering, to determine what the facts are?—No; that part of the inquiry was left entirely to Dr. Tidy and Dr. Beale, I think.

10,928. Dr. Tidy has confined himself, I think I may say, in his microscopic examinations, entirely to mud?—Yes, I think that is so.

10,929. With regard to your opinions as to the slowness of oxidation, as stated in those figures which you have given us, which you took, you say, from laboratory experiments, you yourself have just referred to certain actual observations in polluted rivers which you have recorded in the Rivers Pollution Commission Report?—Yes. I have given you the result of one on the Irwell.

10,930. Do they not contain observations which show by the flow of the river a destruction of organic matter quite as great as anything that Dr. Tidy suggested?—No, I think certainly not.

10,931. I will ask you to look at the report; but first I will come to your evidence about the Irwell. In one case you found that after a certain number of miles there was an increase of pollution?—Yes.

10,932. Is there the slightest doubt that that was caused by the interposition of polluted matter between the two points?—Certainly it was not, because I have examined every yard of the run between the two points.

10,933. Do you mean to say it is your opinion, as a scientific man, that the river in a certain number of miles of its flow was increased in pollution?—I did not say that. I said that probably the water which was examined after a certain number of hours was not the same water as passed over Throstle Nest Weir at the commencement of the flow; but I say that I have observed constantly, even in the laboratory, an increase in the soluble polluting matter in a water, and I have attributed it in those cases to the solution of a portion of the suspended matter in the water, and that is also probably the case in this instance.

10,934. (*Professor Williamson.*) The insoluble

*Dr. E. Frankland.*

6 March 1883.

becoming dissolved up?—Yes; that is a thing that will sometimes occur.

10,935. (*Mr. Bidder.*) Now, I will draw your attention to one of your own recorded observations upon the River Irwell. I do not know what the distance between Throstlenest and the Mersey is?—Eleven miles.

10,936. I see you record upon the 11th of June in a certain year that the organic carbon at the head of that reach was 2·134, which, at the time of reaching the Mersey, was reduced to 1·35?—That was the occasion upon which the great reduction took place.

10,937. That was about 32 per cent.; from 30 to 31 per cent.?—Probably it was. I will take your figures.

10,938. The remarkable fact, I see, according to you, is that, whilst that was taking place, the organic nitrogen had actually increased?—Yes; but to a very unimportant extent, that is to say, within the error of experiment, I should say; it is ·002 practically; the organic nitrogen, you may say, remained practically the same.

10,939. What had become of the organic carbon; did it vanish in the form of carbonic acid gas?—That would be the conclusion that would be drawn if there were no other possibility.

10,940. Is not that the right conclusion?—I doubt it.

10,941. What is the alternative?—Still, I am not prepared to say it might not have occurred upon this occasion, because the river was then in a state of putrefaction; and, as I have said, when putrefaction goes on rapidly, and generates marsh gas, that would carry away the carbon, but not the nitrogen.

10,942. I also notice that you also give the Darwen as coming under your observation; what length of river is given in this experiment?—Thirteen miles.

10,943. The organic carbon which, at the beginning, was 2·127, was, at the end of it, 1·89; and the nitrogen, from ·295, has fallen to ·141; so that, if these figures are correct, from some source or other there had been a loss of 50 per cent. in a flow of 13 miles?—Yes; and the explanation of that is that the volume of the river is doubled by the reception of unpolluted water between the two points.

10,944. But is that so?—As far as we could gauge the river between the two points, that was so; you have it in the report.

10,945. But having it in the report does not make it the fact, you know; we have long got beyond that?—There is no doubt that the river was very largely increased. I followed it down all the way for the 13 miles on foot.

10,946. (*Professor Williamson.*) Did you take occasion to examine the composition of the water that flowed in, so as to ascertain whether it was pure?—I did not examine every stream which came in, but I examined the Ribble, which is an unpolluted river running very nearly side by side with this, and took the composition of the water coming in, as being the same as that of the River Ribble, which was very much purer than the water of the Darwen.

10,947. (*Mr. Bidder.*) How are we to reconcile your evidence as to the number of hours and miles of flow which would be sufficient to destroy pollution, with the facts which Dr. Tidy has given us, that the River Thames above Teddington (at any rate a few years ago, if not so now), after receiving the sewage of a million of inhabitants, was drinkable water at all times?—I do not think it is at all times a drinkable water.

10,948. Still, it was so near drinkable, that it is the subject of a difference of opinion between you and Dr. Tidy whether it is or not?—Yes, that is so.

10,949. That being all the difference of opinion, the statement is one which, for quoting purposes, might very fairly be taken?—I would explain it in this way, that there are, between those two points, Lechlade and Hampton, where the water companies take the water supply, a great many affluents coming in, more especially the Wey, which comes in immediately above this point, and is a considerably purer stream than the Thames; there is also an immense quantity of chalk water in the shape of chalk springs coming in at Reading, rising up in the bed of the Thames; then there is, above Hampton, a state of things very favourable to the purification of the river, namely, an enormous filtration of the river through the gravel there; it sinks into the gravel, and comes out again below the next look; indeed, at the present moment, the Lambeth Water Company is drawing a quantity of its supply from this gravel water.

10,950. (*Sir John Coode.*) Can it be seen distinctly passing through the gravel?—It cannot be seen; at least, I have not seen it, except in the Lambeth Company's works which they have intentionally sunk down into the gravel. So rapid is the supply now, that they get nearly the whole of their supply from that source, and I have proved, from analysis, that the water is very much purer than the Thames water which is flowing immediately above that part of the river.

10,951. (*Mr. Bidder.*) Therefore you argue that it is Thames water, because the analysis shows that is different?—It is Thames water, no doubt.

10,952. Do you seriously suggest that any considerable body of river water flowing down the River Thames, takes a dive into the gravel, and, after passing through the gravel, comes up again into the body of the river?—Yes, I do.

10,953. Although it has an open channel to run in?—Yes; it can be clearly shown that it does.

10,954. (*Sir John Coode.*) What you think is, that the weir creates a head which drives it below the gravel?—Yes, that is what I mean.

10,955. (*Mr. Bidder.*) I believe each individual weir makes a head of about seven feet?—Yes, I believe so; but there are many weirs. I have not the slightest doubt about the possibility of its being as I say.

10,956. Still, your affluents have not got rid of the sewage. Now, I will draw your attention to this, that when you have all your affluents in the river, the entire gauging of the Thames, affluents and all, is only between seven and eight times the quantity of the London sewage; and, inasmuch as you had, at the time that Dr. Tidy speaks of, the sewage of a million people, which is equal to a quarter of the London sewage, you would have contamination in the upper river in the proportion of 1 to 28?—But one million people do not drain directly into the Thames.

(*Dr. Stevenson.*) But, in relation to that, may I interpose by asking, are there a million of people draining now into the Thames?

(*Mr. Bidder.*) Not now.

(*Dr. Stevenson.*) I think the number was stated in a paper which was recently issued at 600,000?

(*Witness.*) That was so stated in the year 1874.

10,957. (*Dr. Stevenson.*) You say that the waters of the Wey are purer than those of the Thames?—They are purer in flood time; but, in perfectly dry weather, there is not much difference between them.

10,958. (*Sir John Coode.*) Have you put before us all the points you wish? I am afraid you were rather interrupted in the explanation you were giving us?—I think I have stated the main points as regards the purity, namely, the influence of springs in the bed of the river; the influence of comparatively unpolluted affluents which, however, is the least important of the three conditions, and especially the flow of a large volume of the river water through gravel above Hampton. That, as I have shown repeatedly, is a very powerful purifying process; a passage through five feet of gravel is worth more than a flow of 100 miles in a river.

10,959. Would not that gravel, in process of time, become polluted itself?—No, there is a true process of oxidation going on there, and even when raw sewage is used under intermittent filtration, there seems to be no blocking up of the gravel, the organic matter is really burnt up.

10,960. (*Mr. Bidder.*) Have you any experiment to show that any part of the water which flows down

the River Thames does pass through gravel in that way?—I have seen it in the gravel.

10,961. But that is not the same thing, because you have seen water in the gravel, that may have been either water in the stratification, or water which had percolated in from the Thames, but that does not show that it goes back to the Thames?—If water is flowing over a bed of gravel, and a weir dams it up, and there is communication between each side of the weir, it is almost a matter of necessity that a large quantity of water must pass through the gravel.

10,962. I ask you the question, have you any observation whatever to show that any appreciable quantity of the water in the river does perform that operation?—I have seen an enormous volume of water pumped out from by the side of the Thames, and this water I have shown to be identical with the Thames water, as regards the inorganic constituents; and, inasmuch as that water was immediately below a weir, I cannot doubt that it passed from the upper side of the weir and the lock to lower down the river.

10,963. Conceded that if you put a well down in a gravel stratification in the neighbourhood of the Thames, you can get enormous quantities of water out of it, and that that water is coming out of the Thames, flowing out from the bottom of the Thames, and being lifted by pumps; yet I ask you have you any observation to make as to the passage of any considerable portion of water, first, into the gravel, and then by nature, without any pumping, if you can help it, back again into the river?—I have no actual observation of it, but it must be so.

10,964. (*Chairman.*) Upon the principle of water finding its level?—Yes, upon the principle of water finding its level, it will pass easily through coarse gravel.

(*Sir John Coode.*) I think, discuss it as you may, it is a question of the surrounding conditions, it may, and it may not be so.

(*Mr. Bidder.*) I am sure Sir John will agree with me, that it is not a question in which you can say must be; I am not denying that there is any portion, but I am doubting whether there is any appreciable quantity that passes in that way.

10,965. (*Dr. de Chaumont.*) You said, just now, that the passage of water through gravel caused a diminution in the organic matter of the water, and you considered that to be a case of pure oxidation?—I do, because I find that even when gravel has been used, for the filtration of sewage for five or six years there is no more organic matter in it at the end of that time than there was at the beginning.

10,966. Is not that due to the operation of the bacteria?—That opens up the whole question of the functions of bacteria. I think that oxidation is, at all events, helped by the action of bacteria.

10,967. You did not mean to say that it was entirely due to oxygenation?—No, I meant it was due to the organisms in the gravel, as well.

10,968. (*Sir John Coode.*) Can you point out any case in which the gravel has remained the same after five years' use?—Yes, there is the case of the Beddington gravel. I analysed the gravel after it had been used at the Beddington sewage farm for five or six years. I also analysed some gravel at the same place, through which the sewage had not passed, and found the proportion of organic matter almost exactly the same in the two samples.

10,969. Have you any other case that you could mention?—Yes, there is the case of laboratory experiments, in which sewage had been continuously filtered, through five feet of gravel, for several months; and upon analysis, the gravel did not show anything more than a very small increase, if there was any at all, in the amount of organic matter.

10,970. (*Professor Williamson.*) I presume that was sewage containing suspended matter, and not clear sewage?—No, the suspended matter was taken out, by a little apparatus, in my laboratory experiments.

10,971. Therefore, the sewage did not contain suspended matter?—In the Beddington sewage farm, of course it did.

10,972. (*Mr. Bidder.*) When you refer to the instance of the sewage farm, is not the process of filtration by gravel, upon a sewage farm, what is known as intermittent downward filtration?—Yes.

10,973. That is very different from what takes place in the bed of the river, you cannot have intermittent downward filtration there?—Yes, I think you would, from the varying level of the river.

10,974. (*Sir John Coode.*) And, moreover, you would not have the vegetable growth in the river that you would in the Beddington Farm?—My experience has been mostly upon farms where there had been a crop grown; but I have investigated an intermittent filter, on which no crop was grown.

10,975. Are you right in that?—Yes, in the first year on the Methyr Tydfil intermittent filters there was no vegetation, but after the first year they planted cabbages.

10,976. (*Mr. Bidder.*) As I understand, you send a certain quantity in upon the filter, and then stop, and the consequence is, that the air passes over the ground; then you again pass over fresh sewage, and again stop, so that you are constantly reoxygenating the gravel, and preparing it for another dose of sewage; but that cannot go on under the bed of the river?—No, but still there is no doubt that the filtration through the gravel does oxygenate the water to a very large extent; we see it also in the case of surface wells.

10,977. Now you state also that the condition of the Thames is becoming worse, and I must ask you a question upon that?—I did say so.

10,978. What is your evidence of it?—There are banks of mud, which are found in various places, and especially in the higher parts of the river.

10,979. I want you to be very precise about this. I want you to say what proof you have, in support of that opinion, that the condition of the river is becoming worse; you say, first, the banks?—Yes, the banks; under the very windows of the Houses of Parliament there is a mud bank, which contains a good deal of sewage. Then I go by the appearance of the river.

10.980. With regard to the banks of mud, you made a considerable number of observations in the river Thames, for the purpose of the last inquiry into mud banks, in the year 1878–79, I think?—At the close of 1879, and they extended into 1880.

10,981. But your observations were made in 1878, were they not?—They were made towards the end of 1879, I think.

10,982. And you had an opportunity of examining the river again last year, had you not?—I have had no opportunity of examining the river, except one.

10,983. You have had a great many samples of water to analyse?—Yes.

10,984. And of mud too?—No, Dr. Tidy did all those.

10,985. You had the opportunity of studying them?—Yes, but I have not studied them.

10,986. Can you give any observations at all, comparing 1879 with 1882, to show that the river is in a worse condition now, than it was then?—No; when I made that statement I meant from observation of the appearance of the river, and from the quality of the mud dredged up in various places in 1879.

10,987. Forgive me for pointing out that one observation will not show progress?—No, one observation will not.

10,988. We must have two at any rate; now, what is the evidence of progressive impurity?—I say from the appearance of the river, it is progressing in impurity. I have seen after the opening of the main outfalls large quantities of fæces floating up with the tide past the pier at Westminster Bridge.

10,989. You have seen that, you say, since the outfalls commenced?—Yes, since the outfalls commenced.

*Dr. E. Frankland.*

6 March 1883.

10,990. Where those matters came from you do not know?—No.

10,991. Were they in large quantities?—Yes they were very numerous.

10,992. (*Sir John Coode.*) More than could have come from vessels and barges upon the river?—Yes.

10,993. (*Mr. Bidder.*) When was that?—That would be about the year 1873, I think.

10,994. Again I ask, where is the evidence of progressive impurity?—I never saw that before, and I saw it then, that is progressive evidence.

10,995. Pardon me, in the first place it is ten years ago, and further, if it is evidence of anything, it is only evidence of the fact that the condition of things is different from what it was before the outfalls were opened; does your observation enable you to say, that the condition of London, between the bridges, is worse than it was before the outfalls were opened?—I have never said that.

10,996. I beg your pardon?—I never said anything of the kind.

10,997. You said you saw these things floating about in 1873, and you never saw them before?—I meant I never saw them before, since the outfalls were opened. I had seen them before that.

10,998. Besides that eye observation 10 years ago, and remembering that you have been employed scientifically in 1879 and 1882, have you one single observation to point to that suggestion of progressive impurity?—Yes, I have noticed the condition of the mud more especially below the outfalls. About the year 1860, I used to yacht a good deal upon the Thames about Erith and that district, and certainly at that time the mud on the banks of the river was in a much less foul condition, than it is now, or was three or four years ago, when we inspected it for the Thames Conservancy.

10,999. You are now speaking not of this part of the river here, but of below the outfall, and you say its condition, according to your recollection when you used to yacht in the river in 1860 (as a young man, I presume), is different from what it was when you observed it in 1879 scientifically?—Yes, that is so.

11,000. I presume I am not wrong in saying you were a young man in 1860?—I was old enough to know what mud was.

11,001. Do you see much of the river now?—I cross the river four times a day as a general rule.

11,002. (*Chairman.*) Your opinion is based as I understand, not upon any laboratory experiment, but on your personal observation as one of us, I might say?—That is so.

11,003. (*Mr. Bidder.*) What part of the river do you see every day?—I see it as I cross between Charing Cross and Cannon Street.

11,004. Is that part of the river getting worse?—Yes, I think so.

11,005. This is from observations taken from a railway carriage crossing a railway bridge?—Those are daily observations, but you know I have had many opportunities, from making special trips upon the Thames, of observing what its condition is.

11,006. But you have been specially engaged for some months past for the purpose of proving the pollution of the river?—Not upon the river.

10,007. But scientifically?—Yes, in making analyses.

11,008. And you have nothing to bring forward?—I think I have brought forward a good deal.

11,009. I will just deal with the points upon which, if I followed the facts, you relied, as charging us with polluting the lower part of the river upon certain occasions. I gather that you rely more upon the ammonia, than upon the relation of nitrogen to carbon?—I rely upon the ammonia entirely where the river is mixed with a large quantity of sea water.

11,010. You have given up the ratio of nitrogen to carbon, where there is a large quantity of sea water?—Yes.

11,011. It is interesting to observe the disintegration of creeds, you did believe in the ratio of nitrogen to organic matter?—Yes.

11,012. And you did upon the last occasion, believe in the ratio of the nitrogen to carbon in the sea water?—Yes, but there is no mud in sea water; the mud of the sea water, if there is any mud at all, is practically free from organic matter.

11,013. You gave us certain occasions, for instance, the 11th of July and the 21st of June were the dates you gave me?—Yes, those were the dates upon which Dr. Tidy's samples were taken.

11,014. Those were the dates you referred to as indicating a large quantity of ammonia, one I think you said you could only account for by saying that the sewage was running up in a sort of eddy along the bank in the neighbourhood of Beckton?—July the 11th and June the 21st were the two dates I gave and the localities were at Blackfriars Bridge in a line with the Monument at Charlton Ballast wharf, at Charlton Pier at Woolwich, at 200 yards below the entrance of the Royal Albert Dock, and at a little below the Clock Tower at Beckton.

11,015. I understood you to say, and I followed you as carefully as I could, that you found below the Clock Tower at Beckton, that there was a quantity of ammonia which exceeded the average in sewage, and that what that indicated to your judgment was that there was a flow of sewage running up from Barking?—From the northern outfall.

11,016. Have you taken so little trouble in examining these observations as not to know that that was not a sample of the outfalls sewers at all, but a sample of the Beckton Gas Works sewage, and is so shown by Dr. Tidy in his observations; look at No. 44 on Table 1: "Sewage from Beckton, July the 11th, ammonia 3·28;" that is labelled by Dr. Tidy and properly labelled "Sewage from Beckton?"—Then that is a mistake of mine, undoubtedly, but I was not bringing any particular indictment against you in that case.

(*Chairman.*) There is no question here of indictment against anybody, it is a question of fact, that we have to enquire into.

11,017. (*Mr. Bidder.*) That had nothing whatever to do with the river, that is perfectly clear?—No, I do not know where I got hold of it. It might be that the numbers in some instances had been transposed, perhaps.

11,018. Then that observation, you will agree, falls to the ground?—Yes, and therefore I have no necessity to explain how such a thing could happen. I confess it rather puzzled me.

11,019. It shows what a chemist can do in the way of hypothesis when necessary?—It was not a very violent hypothesis after all.

11,020. Now I will ask you another question, you have put in a large paper or "Report" as it is called, which purports to deduce certain results from the amount of matter which came from the sewers in the year?—Yes.

11,021. I must ask you some questions upon it. Table A. is simply a record of the rainfall and the weather observations?—Yes, that is the official record published by the Register General.

11,022. That carries me on to page 18, where I find Table B. I notice in the first place that in getting your average you have mixed up observations from the old days before the Metropolitan Outfalls were made at all, of particular sewers in London, with recent observations of the Metropolitan Board of Works Sewers; in point of fact the first page is almost exclusively, with one or two exceptions of old sewers that we have nothing to do with?—I have availed myself of all the observations upon the composition of London sewage that I could find. As far as the storm samples were concerned, I was driven to take the results obtained (and which are published in an official form) by Professor Hofmann and Mr. Witt.

11,023. I have very little to ask you about Table B. because I see you bring out as the result the average of what I will call normal sewage?—And below, even, your own average.

11,024. I do not complain of that. I make it 24 and a fraction, and you make it 23·36 grains?—Yes.

11,025. Now I pass on to page 21, where I suppose what you intend to do in section 2, is to get the average of the discharged matter when the rainfall is between ·01 and ·30, and apply it to all the cases in the year in which there was that rainfall observed?—Yes.

11,026. That is your mode?—Yes, that is my mode.

11,027. Again, I beg to observe these are mixed up observations, ancient and modern?—Yes, unfortunately modern observations are so very few upon the sewage with any rainfall at all.

11,028. (*Chairman.*) I understand you to have struck out the observations in 1857 and 1869?—Yes, I have struck out the first two observations in 1857 and 1869 and the first observation made any use of, is April the 7th 1869; that is the only one before 1878.

11,029. (*Mr. Bidder.*) You have done something even worse or more inaccurate here; you have struck out all the low results, and so got a high average?—Yes; but you did not complain about my striking out the high ones in the former table.

11,030. That is a very smart remark, but I would point out this. I did not ask you to strike out the high ones before; I suppose you had your own reasons for doing it?

11,031. (*Chairman.*) Why did you strike out the low ones in this table?—I struck them out because they are obviously abnormal, they are much lower than fair weather sewage. If all the cancelled numbers were retained in striking the averages, the final result, as regards the quantity of mud annually discharged into the Thames, would not be very different. Thus in 1878 it would be 434,573·2 tons of dry mud instead of 505,041·8 tons; and in 1879 it would work out to 461,808·9 tons instead of 541,765·5 tons. The average amount of suspended matter per gallon of dry weather sewage would be 25·60 grains instead of 23·23 grains. With a rainfall not exceeding ·03 inch, it would be 31·18 grains instead of 42·91 grains. When the rain exceeded ·03 inch, but fell short of 1 inch, the average would be 60·09 grains instead of 90·02 grains; and when the rainfall was 1 inch and upwards it would be 116·42 grains instead of 134·94 grains.

11,032. (*Mr. Bidder.*) But does it follow that they are obviously abnormal?—I think so.

11,033. Are you not aware that this has been given in evidence over and over again by gentlemen who have observed the sewers, that if you have a rainfall after a long drought, you have at first a very heavy discharge of suspended matter, but that if the rainfall is followed by successive falls of rain, you will have very little discharge of suspended matter in the after days?—If you say there are many such data, I should like to know where they are. I know of only one determination.

11,034. If there has been a long drought, and then comes a smart fall of rain, the matter which has been collected in the sewers, is swept down the sewers, is it not?—Yes.

11,035. And carried out into the Thames?—Yes, but not so suddenly as you suppose; it will go on for a couple of days, I imagine.

11,036. If you have several days of rain, the first day's rain will give you a very large discharge, because it will give you the accumulation of weeks; the other cannot give you anything like so high a rate of suspended matter discharged, because the first heavy rain would have cleared out the accumulations?—The average suspended matter would be high, even for a week, I should say.

11,037. Have you any observation to show that?—Yes, there is one in the first table which will show what I mean, and that is why I have struck it out. On April the 8th, 1857, at page 18, there was no rain that day, but there had been some upon the previous afternoon, and the sewage flowing from the King's Scholars Pond sewer, which was one of the largest sewers, draining the whole of Belgravia, contained no less than 41·1 grains per gallon of suspended matter. Now that, as you will admit, is abnormally high, and it was very properly struck out, but that was from the rain of the previous day.

11,038. Now, I will draw your attention to another thing. I think you heard the evidence of Sir Joseph Bazalgette in the last case, and you are aware that since the year 1869, a system of catch-pits, frequently cleared, has been introduced throughout London, for the express purpose of preventing the road matter from getting in any quantity into the sewers?—Yes, and I do not believe they answer their purpose efficiently.

11,039. Again, I ask, have you any evidence or observation to confirm that statement?—Yes, I have made numerous observations as to the effect of such catch-pits, not merely in London, but in many towns in the United Kingdom, more especially in the provincial towns.

11,040. Confining ourselves to London, have you any observations which justify you in making the assertion that the efforts of the Metropolitan Board of Works in introducing catch-pits into London have been perfectly futile?—I did not say they had been perfectly futile.

11,041. You said they were not efficient?—I said they had not been efficient.

11,042. You mean to say that they have been partially futile?—They do collect a certain portion of the mud, but a very small part.

11,043. In this second section in your report, on page 21, from 1879, you have only four observations?—Yes.

11,044. And three out of the four you have rejected?—I have rejected them.

11,045. I can hardly grasp why, in trying to get the average, you have rejected the last three cases, they were facts; in those cases you have the rainfall coming down?—But they were exceedingly minute in the last case; in the first, ·01 inch, it was "thin rain, afternoon and evening." Now, thin rain to that extent only, as a rule, has very little effect upon the sewage; it is absorbed by the dust in the street, and does not get into the drains at all.

11,046. (*Sir John Coode.*) When you say it has very little effect upon the sewage, you mean to say that its power to carry matters into the sewers is very slight?—You will see that that is all misty rain that has been rejected.

11,047. (*Mr. Bidder.*) But the ·03 is the very maximum rainfall of this section?—Yes, "with fog and thin rain till afternoon; cloudless," and so on "afterwards."

11,048. Will you let me draw your attention to this, that when the same descriptions give you a big result, you do not reject them; "foggy in morning, overcast with occasional misty rain" on October 22nd, 1879, produced you 32·82?—I have tried to be as fair as possible in the construction of the averages, and, I think, you will allow that I have been very good to you in the first table.

11,049. I do not think so. I think you have made a little concession there in order to get a gigantic advantage here. Now we proceed to section 3, "rainfall above ·03 and under ·1," here again there are only two observations before the year 1871?—I anticipated that you would not accept that without an objection; those were the only two samples of sewage ever examined with that rainfall.

11,050. Section 3 has only two observations altogether, and they are both, as I say, before the year 1870?—Yes.

11,051. And they neither of them relate to the metropolitan outfalls at all?—I am very sorry I cannot give you better evidence; but you have not got it either. Those are the only two available samples which have been taken.

11,052. As a matter of fact, these averages have been drawn from two observations only which have been taken, and you reject one of them?—It is not

*Dr. E. Frankland*

6 March 1883.

an average, and I think it is not fair to put it in that way.

11,053. Then you really present a table based upon such facts as that as having any reliable result?—At all events, it is the best that can be had.

11,054. A table based upon an observation from two sewers 14 or 15 years ago, before the present system was introduced, taking the high figure and rejecting the lower one, do you seriously present that to the Commission?—The table was one of a long series of results obtained in the laboratory, and the samples were all taken from that one, Northumberland Street Sewer; and though I am very sorry that that is the only sample I can submit to the Commission, I think the number, as far as it goes is trustworthy, and moreover you see it comes very fairly between the two other tables, that is to say, between the average of 42·9 in section two, and the average of 134·94 in section four.

11,055. Now we come to section four from ·1 of an inch up to anything above it?—Yes.

11,056. I see here again only two observations of the outfalls?—That is entirely the fault of the Metropolitan Board of Works.

11,057. It is our fault that you have not got any more observations; now there is some limit to what we can bear, but why is it our fault?—I ought not to say "fault," but really there were many opportunities which might have been used for determining what was the composition of the London sewage in stormy weather. As a matter of fact, I am very sorry to say it, because the chemist who might have taken these samples and given us the result is now no more, and cannot defend himself; but still, as a matter of fact, these samples which were taken at the northern and southern outfalls are always suspended when there is a heavy rainfall; they stop, and then they begin again when there is finer weather. I do not mean to say that that was done of purpose, but still there is the fact.

11,058. Do you say that the late Mr. Keates carefully suspended his samples during flood?—I do not suggest that. I merely give the fact that when there is a heavy rainfall there are no samples taken and no analysis made.

11,059. Were not those very samples taken by Mr. Keates?—Which samples do you refer to?

11,060. Those samples which you used in 1879?—No, they were my own. I took them myself.

11,061. Did you take those samples upon the 30th and 31st of December 1879?—I did not take them myself, but they were taken for myself and Dr. Tidy by an officer of the Thames Conservancy, and Mr. Keates took some at the same time.

11,062. And gave evidence?—Yes, those are the only examples of storm sewage which were taken in the whole series.

11,063. Now as all the Honourable Members of the Commission have not the book, I will read the figures: "1879, December 30th, ·21 of an inch. "Thunderstorm between 1 and 1.30 p.m. Frequent "heavy showers. Sample taken at northern outfall "at 3.25 p.m., showing 119·4 grains of suspended "matter per gallon, of which 77·4 are mineral, and "41·98 organic." Then I will read the next entry, which refers to the very next day, the 31st December, with an almost identical rainfall: "Rainfall, ·19. "Weather, frequent rain. Observation taken at "northern outfall at 3.15 p.m.," almost at the same time of day. There instead of 118 grains of suspended matter you only find 29·69?—Yes, that is so.

11,064. Is not that the strongest possible corroboration of what I was suggesting to you just now (this is a violent thunderstorm between 1 and 2), that the first violent storm swept the great amount of accumulated matter from the sewer, and then afterwards, however heavy the rain may be, you get very little?—You will observe that the thunderstorm occurred between 1 and 1.30, and that sample was taken at the northern outfall at 3.25 p.m., now there would not have been time for the great mass of the stuff which was brought down by that storm to reach the outfall.

11,065. But by the next day there would be 24 hours interval?—Yes.

11,066. Have you any doubt that the reason of the small quantity brought down by the same rainfall the next day, was that the first violent flow swept the accumulated mass out of the sewer?—I have very considerable doubt as to that being the case. I think the "frequent rain" of the following day being distributed over a much greater length of time, would leave a good deal of the detritus stored up in the sewers comparatively untouched. No doubt the thunderstorm upon the 30th would sweep out a good deal of the material, but I very much doubt whether the ·19, if it had fallen in thunder showers as it did upon the 31st of December, instead of falling at intervals, would not have given a different result from this which appears. Moreover, it is rather difficult to get a fair amount of suspended matter in a sample collected at the northern outfall. I have collected a number of samples there, and a great deal depends upon the way in which you use pail for the sample, whether you get the due proportion of suspended matter there.

11,067. (*Sir John Coode.*) When you say at the northern outfall, where do you mean exactly?—In the sewer just before it empties into the reservoir.

10,068. (*Mr. Bidder.*) Now I would draw your attention to a further statement or assumption of which you have no proof. This was an observation taken two hours after a thunderstorm, and you have assumed, have you not, that that quantity of suspended matter which was observed at that particular moment was pervading the whole of the 24 hours?—Yes, I have assumed that.

11,069. That is pure assumption, is it not?—Yes.

11,070. You have no evidence of that as a fact?—I have no evidence of that as a fact beyond this sample, any more than I have any evidence of the low quantities continuing during the 24 hours.

11,071. You say you have no evidence that this continued for the 24 hours; but do you observe on the other hand, that upon the face of your own table you have the evidence that in 24 hours it had fallen from 119 grains to 29?—Yes.

11,072. Is it a reasonable assumption that during all that 24 hours it was coming down at the higher ratio?—It may have been double this quantity at some time during the 24 hours.

11,073. You have no particle of evidence of that?—No; but inasmuch as the main body of the sewage could not possibly have reached the outfall at that time, it is possible that the 119 grains may have been greatly exceeded at some later time.

11,074. That is a pure assumption, is it not?—No doubt.

11,075. You assume that that proportion of suspended matter lasted the whole 24 hours, although the thunderstorm only begins at the thirteenth hour? I have taken the quantity of water which fell upon the 120 square miles of London, or whatever the area is, to the depth of ·2 of an inch.

11,076. You assumed that every gallon of water which fell upon the area of London when ·2 of an inch of rain fell carried that proportion of suspended matter with it?—Which is a very probable assumption.

11,077. Having got an observation at the northern outfall just two hours after the storm came on, which was sweeping the solid matters out of the sewers into the river, you assumed that that was coming out the whole of the 24 hours of the day?—Yes.

(*Sir John Coode.*) What I understand Dr. Frankland to say is, that there may have been periods in the 24 hours when the quantity flowing out might have been very much larger.

11,078. (*Mr. Bidder.*) No doubt; but still I am dealing with the assumption. (*To the witness.*) Now do you know that that particular thunderstorm followed a long period of dry frosty weather?—Yes, that was so.

11,079. Now, when I come to look at your application of these averages, I find that you have actually put down the 31st of December on which you found 29 grains to the gallon, and treated it as if it had been 134?—I have used the average number that I have got in section 4 for the average amount of rainfall.

11,080. Against the fact that the effect of your rainfall that day is only 29 grains to the gallon, you have carried it into the average of 134?—Yes.

11,081. Between four and five times as much as you know from observation was brought down?—That observation was taken at a time far distant from this thunderstorm, and, although there was a fall of rain of ·19 during that day, I do not believe that that amount of suspended matter represents the normal condition of sewage under that rainfall, because it is exceeded so very frequently in dry weather; it is enormously exceeded in dry weather.

11,082. As far as the main outfalls are concerned, you have only two observations, and you do there as you have done before, reject the one that was small, and take the one that was big?—Yes.

11,083. That is your notion of taking an average?—But there are a number of other corresponding observations in the tables, so you cannot object to it.

11,084. Now passing from that, Table C gives us the working out and the application of these averages for the two years 1878 and 1879?—Yes.

11,085. Then, passing to page 24, I will take the one day on which 2½ inches of rain fell. I suppose that the 3,676,000,000 gallons represents the total quantity of rain that fell upon that day?—Plus the water supply.

11,086. Have you allowed nothing for evaporation?—Yes, I have, 20 per cent. I know that, if it were in the country, 20 per cent. would not be sufficient, but the evaporation in London I conceive to be very small, as the water runs directly from the roofs and roads and streets into the sewers.

11,087. I do not know whether you are aware that the 3,676,000,000 gallons is about seven times as much as can possibly go through the outfalls of the Metropolitan Board of Works when they are running chock full?—I do not mean to say that all this came from the mouths of the northern and southern outfalls. A great deal of it would come from the storm outfalls, which would be all running very heavily during that flow.

11,088. But, pardon me, it cannot even get through the storm outfalls without flowing through the sewers. Are you aware that those quantities that you have represented are more than all the sewers in London can carry?—But do you represent that upon this day 2½ inches of rain did not fall?

11,089. I do not at all?—Then where did it go?

11,090. That is not my business to show?—Possibly it did not all go down the sewers to the river.

11,091. Now I will ask you, are you aware that this quantity far exceeds the united capacity of all the London sewers?—I am not aware, indeed, of that, and I should be surprised to find that it was so; but there had been such things as sewers bursting from overcharge during rain.

11,092. Did the sewers burst upon any of these occasions?—I do not know that they did.

11,093. Now Table D. is a development of the tables arrived at in the way that we have indicated?—Yes.

11,094. And is as much entitled to credibility as they are, and no more?—Just so.

11,095. That will do for these tables. Now let me ask you about some other matters. You have spoken a good deal about sewage working its way up the river, I suppose it is not more likely to work up the river than it is to work down?—No, it works a little more down than it works up, and in time of flood, as I have stated, it works down the river altogether.

11,096. You have spoken about the progressive impurity of the river, and I will draw your attention to this. You said that at Teddington the ammonia which you now take as your chief guide was 0·02 parts in 100,000?—I said it never exceeded or it was below 0·02 parts, but the exact number is given in the analytical table of Professor Way's results.

11,097. I want to draw your attention to your Table 10 on page 11 and Table 11 on page 12?—Those are mine.

11,098. At Teddington (and, I suppose, it is fair to take low water, because then it is not contaminated by any of the sources of contamination below) you show the ammonia to be ·012?—Yes, that is on September 22nd.

11,099. Now turn to the next table, which relates to the very same day, but to a lower part of the river?—Those are Dr. Tidy's tables.

11,100. We will take low water at Southend, because it has then its least connexion with the sea. ·01 at each low water?—That is so.

11,101. That is rather purer than at Teddington?—There is rather less ammonia, but that is not very wonderful.

11,102. Then, so far as ammonia is an indication of pollution, the water at Southend on September 22nd was rather better than at Teddington?—Yes; and I should have been much surprised if it were not so.

11,103. At low water, you know, at Teddington, the water is water which has come from 8 or 10 or 12 miles higher up the river?—Yes.

11,104. And the water at Southend is practically sea water?—Yes.

11,105. But, whatever it contains, the fact is distinct, and it is a fact that the condition of the water is better at Southend than at Teddington?—The condition of the water as regards ammonia.

11,106. (*Chairman.*) The amount of ammonia is about the same, is it not?—Yes, the amount of ammonia is about the same.

11,107. (*Mr. Bidder.*) Between those two points you have the whole mass of the London sewage, and all the accumulations, if you are pleased to say that there are accumulations?—Yes.

11,108. And the tendency, as you admit, is, on the whole, down the river?—Yes.

11,109. Now, how is the progressive impurity consistent with the fact that the water at Southend is as pure as it is at Teddington?—It is perfectly consistent, because it is mixed at Southend with an enormous quantity of sea water.

11,110. But I think your own figures show us that the water at Southend has about 25 per cent. of river water?—Not upon that day.

11,111. Not upon that day; I am thinking of another day?—It was, 90 per cent. of it, sea water, I think, upon this day.

11,112. Mr. Mansergh's tables showed 27 per cent. of fresh or river water at Southend upon one day?—The sea water at low water at Southend was 92·6 per cent. of the whole upon the 22nd of September, so that, as it was nearly all sea water, you could not expect much ammonia there.

11,113. Let us go a little above Southend; let us go to Gravesend; at Gravesend you show still better for ammonia?—At low water it is ·06.

11,114. I beg your pardon; one is ·06, and the other, at the surface, has no ammonia at all?—No; but as I have explained, it is no use going on with the ammonia at all, because it is only a positive quantity.

11,115. It only shows what is against us, and does not show anything for us: "Heads, I win; tails, you lose." You say the presence of ammonia indicates sewage, and when it is not there you say it does not indicate that there is not sewage present?—The chemists will understand what I say as to the presence of ammonia; it is nothing to me whether it is in your favour or against you. What I am saying is, that it is a well known fact that ammonia in water very soon disappears.

11,116. How can that be a true indication of sewage which is an accident; which may be absent while sewage is present, or may be absent because the sewage is absent; it may be present because sewage

*Dr. E. Frankland.*

6 March 1883.

is present, or, it may be present for other reasons?—If it is present it shows that there is sewage in the water.

11,117. If it is not present, still, possibly, the sewage is there?—Yes.

11,118. And there is no other way of indicating sewage except by the presence of ammonia?—There is no other way which is feasible in the Thames at Southend and Gravesend.

11,119. What condition is the sewage in when the ammonia has vanished?—The polluting organic matter of the sewage may still all be there.

11,120. What is the test of the presence of polluting organic matter when the ammonia record is pure?—The organic carbon and the organic nitrogen are the indications of polluting matter; the ammonia is not polluting; there may be any quantity of ammonia and no pollution.

11,121. But you told us that the carbon and nitrogen were not to be depended upon?—They are not to be depended upon where there is an admixture of sea water, because sea water contains organic matter corresponding very nearly to the organic matter of the sewage.

11,122. What is the indication of sewage?—Ammonia.

11,123. But when the ammonia has gone?—It is all in your favour then, because we have no other proof of the presence of sewage except ammonia.

11,124. (*Professor Williamson.*) Is there any process known to you by which a smaller proportion of ammonia, less than a grain per gallon, can go out, or does go out, from sewage; is there any case established of sewage losing within a definite time an appreciable quantity, or a small fraction of a grain per gallon?—May I ask, do you mean losing by evaporation?

11,125. Losing any how, so as to show that if it is still sewage containing a grain per gallon, the good of that is gone?—I cannot say that I have any facts bearing upon that, but I have noticed over and over again, the disappearance of ammonia from polluted water when the samples have been kept two or three days, and analysed.

11,126. (*Dr. Stevenson.*) May I ask whether you have examined the water for living organisms in that case?—I have not.

11,127. (*Professor Williamson.*) They might have assimilated the ammonia?—In all probability. The ammonia does not evaporate. Sewage will flow for miles and not lose an appreciable portion of ammonia.

11,128, But you have found that after you have collected it, it does lose?—Yes, I have had samples taken, and duplicate analyses made of them, and they show after two or three days none at all.

11,129. (*Chairman.*) Do I understand you to say that ammonia indicates the presence of sewage?—Yes, when it is beyond the quantity normally present in the river under investigation.

11,130. You have it in pure water?—Yes, in a small quantity.

11,131. And in salt water?—Yes, to a certain very small extent.

11,132. You have at Teddington and at Southend, very much the same amount of ammonia?—Yes; that I explained by saying that the ammonia in sea water is only about $\frac{1}{10}$th of the amount of ammonia in the water at Teddington. There is a very small quantity indeed in sea water; what I said was that I should have been surprised if I had found a larger amount of ammonia at Southend, on account of the quantity of sea water.

11,133. (*Sir John Coode.*) The ammonia in itself is not hurtful, is it?—The ammonia is perfectly innocuous.

11,134. If the ammonia had all gone, might the sewage be equally injurious and prejudicial to health as before?—Yes, I think so, because it still contains putrescible organic matter.

11,135. (*Dr. de Chaumont.*) Have you any experiments to show whether there is any alteration in the amount of organic nitrogen, when the ammonia disappears?—I have made experiments with the view of ascertaining that. I was under the impression at one time that the ammonia was assimilated by living organisms, and that it was transformed therefore into organic matter, but the experiments led to a negative result.

11,136. (*Professor Williamson.*) Have you any facts regarding the process by which ammonia disappears, as you conceive it does, in the presence of organisms; do you conceive the organisms assimilate it?—What I stated was, that I made a number of special experiments, with the object of ascertaining whether, when ammonia disappears in this way from contaminated water, the quantity of organic matter increases; and I have obtained, in every case, a negative result. I found that it did not increase when the ammonia disappeared.

11,137. The organic matter altogether; not organised living beings?—I was under the impression that it was absorbed by organisms, and disappeared as organic matter, but I could obtain no evidence of that.

11,138. (*Mr. Bidder.*) When you stated that sewage in the water might be equally prejudicial to health if no ammonia were present, were you referring to water being fit to drink?—Yes, more especially.

11,139. Of course, nobody would contemplate, at the present day, drinking the water of the tidal reaches of the Thames under any circumstances?—No; but still, at low water, a great deal used to be taken by the shipping, and may be yet for aught I know.

11,140. Have you any observation or experiment leading you to believe that sewage in river water is prejudicial to health otherwise than for drinking?—No; I have no observations to show that definitely.

11,141. When I drew your attention just now to a Gravesend sample on Table 12, at low water, from which the ammonia was absent, and asked you what test, in the absence of ammonia, you would refer to for sewage, you said, the organic nitrogen and the organic carbon?—Yes; but I have said, over and over again, that that test is quite unreliable when there is sea water in the mixture.

11,142. I want to draw your attention to this, that in that very specimen, the organic carbon is actually less than in the water at Teddington?—That may be so, but you will find that the organic nitrogen is in a very high proportion to it.

11,143. The organic carbon is ·206 at Gravesend; whereas, if you look at the previous table at Teddington, it is ·324?—Yes; but look at the organic nitrogen in the two places.

11,144. There is not much difference between them; the one is ·1, and the other is ·06; that is not much to boast of?—It is ·05; not more than half as much.

11,145. The carbon, however, is less at Gravesend than at Teddington?—Yes; there is sea water there probably.

11,146. Does sea water destroy the carbon?—No; but sea water does at times contain less organic carbon than this water did at Teddington upon this particular day.

11,147. It is not quite so, because, if you look at Southend the same day, there was more carbon, so that will not do; there was ·3 and ·216?—At low water it was ·216.

11,148. Because there was the purifying influence of the river which helped it?—It was also, at high water, ·202 on September 22nd, in the second high water sample.

11,149. One is at the surface and the other at the bottom; let me draw your attention to that; so that you must take the mean between them; it is not the sea water which has reduced the carbon, because the carbon is less at Southend than at Gravesend; so, does not it come to this, that by the time the river

has reached Gravesend, by every test that you can point to, it is as pure as it was at Teddington, or as pure, if you like, as the sea water?—Not at all.

11,150. What is there that you can point to which will show that the Gravesend water is not as pure as the Teddington water, on the one hand, and the sea water on the other?—The organic carbon, 20 feet below the surface at Gravesend, was ·494, whilst the organic nitrogen was ·149; those are very high numbers.

11,151. Now you have gone below the surface. How do you know that that was not living organic matter?—It may have been living at Teddington for the same reason, but there it was; it was organic matter, whether living or dead. I do not know that it is any the better for being living.

*Dr. E. Frankland.*

6 March 1883.

Adjourned to to-morrow at half-past 12 o'clock.

# TWENTY-EIGHTH DAY.

## Wednesday, 7th March 1883.

PRESENT:

SIR. P. BENSON MAXWELL, IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR A. W. WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

Dr. EDWARD FRANKLAND, F.R.S., further cross-examined by Mr. BIDDER.

11,152. I have only two or three questions more to put to you; do you know the River Lea?—Yes, I do.

11,153. Can you tell us at all the sewage of how many people is discharged into the River Lea above the intake of the East London Water Company?—That I cannot tell you off-hand, I have a memorandum somewhere about it.

11,154. It is a very large number, is it not?—There is nothing like the sewage that is discharged into the Thames in relation to the volume of water.

11,155. I do not know whether I am approximately right, it is suggested to me that there are about 300,000 people above the intake of the East London Water Company?—I cannot deny it.

11,156. (*Chairman.*) You do not know anything about it?—I do not know anything about it at the moment.

11,157. (*Mr. Bidder.*) You are aware, I presume, of this, that there are a considerable number of sources of pollution in the upper part of the River Thames above the outfalls at Barking, other than the outfalls of the Metropolitan Board of Works?—I should think there are not many, I may say at once that I do not know of any, but I do not mean to say there are none.

11,158. I do not know whether you have heard the evidence which has been given before the Commission, are you aware that the Richmond sewage goes into the upper part of the river?—When I said that, I knew of no other source of pollution, I meant other than sewage; I did not distinguish between Richmond sewage and London sewage. I know that the sewage of Richmond goes in up there; I thought you meant drainage from manufactories.

11,159. Are you aware also that the sewage of a good number of other places, Chiswick and Barnes, also goes in there?—I really do not know how far the sewage of those places is included in the Metropolitan drainage area, therefore it is no use asking me.

11,160. Take it from me that it is not; are you aware that the tributary streams bring in a considerable quantity of sewage?—Yes, that is in evidence in Dr. Tidy's tables.

11,161. Perhaps you are aware also that there is a very large floating population upon the river?—Yes; I am not aware at all how many there may be upon the average at any one time upon the river, but there must be a considerable floating population.

11,162. As regards the pollution higher up the river at Chelsea and Chiswick and this neighbourhood, have you anything which enables you to say that it is attributable to the metropolitan outfalls at Barking rather than to other sources of the kind I have indicated?—Of course my analysis cannot distinguish between Richmond sewage and London sewage, that is quite apparent.

7 March 1883.

11,163. One other matter upon which I desired to put a question to you is this,—you said yesterday, in describing certain experiments of yours with regard to the effect of sewage in water, that, although the amount of oxygen required to oxidise the sewage had diminished by lapse of time, you were of opinion that the sewage was not destroyed because no carbonic acid was formed?—I was not "of opinion," it is a fact that none of it was destroyed, because, if it had been destroyed, carbonic acid gas must have been produced.

11,164. It goes beyond an opinion; it is an absolute fact?—It is an absolute fact.

11,165. Now I will put a few questions to you upon another matter; if it does not follow that carbonic acid gas was formed, yet the oxidation of the sewage produced other combinations which are equally destructive of the sewage as sewage?—That is a very difficult question to answer. I quite agree with you that other combinations would be formed, but we know nothing of them as to whether they are more or less noxious than sewage.

11,166. The sewage has been oxidised or burnt, and the chemists tell us that those are convertible terms,—it is none the less burnt because it has formed another compound of the carbon and the nitrogen with carbonic acid?—You cannot say that it is burnt at all until it is resolved into its products of combustion; the products of combustion are carbonic acid, water, and nitrogen, and those were not formed in this experiment.

11,167. Combining with oxygen is combustion, is it not?—Scarcely; you would not say you burnt up alcohol when you converted it into vinegar.

11,168. Is it not the case that in experiments such as yours, the quantity of carbonic acid that would result from the absorption of the amount of oxygen that was indicated would be so small as not to be distinguishable within the limits of experimental error?—Oh dear, no. I should think probably that a 50th part of it would be distinguishable.

*Dr. E. Frankland, F.R.S.*

7 March 1883.

11,169. I am not a chemist myself, but I have some eminent chemists behind me, so I do not ask these questions without some instruction, and I ask you to reconsider that answer. What, for instance, would be the amount of carbonic acid that would result from your experiment; it is suggested to me that it would be so minute as to be within the limits of experimental error?—Unfortunately the oxygen is expressed in that report by weight, and it would take some time to convert that into volume; the carbonic acid, on the other hand, is determined by volume and not by weight; it would be difficult perhaps to determine it by weight, but there would be no difficulty in determining it by volume.

11,170. Is that in the 6th Report of the Rivers Pollution Commission?—Yes, at page 138; the weight of dissolved oxygen in the mixture before it was enclosed in tubes was ·946, that is to say, there were in 100,000 parts of the water ·946 of a part by weight of oxygen, that is not much less than one part by weight; 16 parts by weight of oxygen would produce 22 parts by weight of carbonic acid, by combining with the carbon. Now nearly the whole of the oxygen is absorbed, you will observe, in the 168 hours, and the quantity of gas boiled off in the shape of carbonic acid was very large indeed; there was no difficulty indeed in estimating it, but I cannot tell you how much there would be unless I knew the contents of the bottles in which the experiments were made.

11,171. Now I will ask you this; there is always a certain amount of carbonic acid in the water, is there not?—Yes, certainly; that was determined in the initial experiment.

11,172. The actual quantity of carbonic acid that would result would depend upon the size of the bottle; that is obvious, but the relative quantity of carbonic acid resulting from this oxidation of the sewage to that which is naturally in the water would be so small as to be within the error of experiment, would it not?—No, it would be nothing like that minuteness; it would be a considerable amount.

11,173. I do not know within what limits you could determine the carbonic acid present, would it be within one per cent. or two per cent.?—You can determine the carbonic acid with very great precision indeed to one-tenth of one per cent. in a gaseous mixture.

11,173*a*. Do you mean present in water?—Yes, present in water.

11,174. Do you mean to say that the errors of experiment are not more than that?—No; I have determined in the air a percentage of carbonic acid which never rises, or did not rise in these experiments, to more than ·01 per cent.; I have determined that over and over again with very tolerable accuracy, that is one-tenth of what I am speaking of now, namely, 100th of a per cent.

11,175. Where is it recorded in this report that there was no production of free carbonic acid?—On page 138 there is a paragraph beginning "It is thus "evident," and at the end of that you will find it stated "whilst, if the sewage had been converted into "inorganic compounds, the carbonic acid as one of "these compounds must have increased in quantity."

11,176. I do not see any determination of the amount of carbonic acid here; I see a general statement?—It was carefully determined before and after the experiment; and there is also in that same paragraph this passage, "But the experiments showed "that, in fact, no sewage whatever was so converted "or destroyed even after the lapse of a week, since "the amount of carbonic acid dissolved in the water "remained constant during the whole period of the "experiment." Now the carbonic acid, I may mention, was determined in each of the six cases.

11,177. What had the sewage been converted into?—Very little of it was converted at all, but what it was converted into, I cannot say.

11,178. (*Dr. de Chaumont.*) Have you any evidence of the absorption of the carbonic acid by the bacterial bodies in the water?—I have nothing very positive; I have made experiments of that kind by putting putrescent mutton broth into an atmosphere of carbonic acid, and the liquid generated bacteria, and, as far as my memory serves me, the volume of the gas did not perceptibly diminish for a week or a fortnight during the time that operation was going on; but I did not make any accurate measurement of that, it was merely a measurement by the eye.

11,179. There is no evidence of the absorption of dissolved carbonic acid in water by the bacteria?—No, there is no evidence that I am aware of.

11,180. (*Dr. Stevenson.*) You would not agree that it is impossible for these organisms to live in the absence of oxygen?—No, certainly not.

11,181. (*Mr. Bidder.*) In air, as I understand, it is a very simple thing to determine with great accuracy the percentage of carbonic acid present?—Yes, it is.

11,182. But in water is it not determined by boiling?—It is determined by boiling—a known volume of water in vacuo—until it ceases to give off any trace of gas.

11,183. In point of fact, it is practically impossible, is it not, to eliminate the whole of the carbonic acid in that way?—I do not think so; when you say the whole of it, there might be a 10,000th part of it left behind, but practically, you get rid of it.

11,184. But within one per cent. you cannot determine it, can you?—I have made many scores of determinations of this kind, and I have not found any difficulty in doing so.

11,185. I believe about 45 parts in 100,000 is the normal proportion of carbonic acid in water?—That depends altogether upon what the source of the water is. In chalk water you will have more; you cannot put it in that way.

11,186. (*Chairman.*) There is no settled quantity, we may take it?—No, because in chalk water there is a good deal of carbonic acid held in combination until it is boiled.

11,187. Science has not recognised a fixed quantity of carbonic acid as the standard quantity for water?—No, it varies very much indeed, within very high limits. Might I say within what limits I have found the carbonic acid to vary. In rain water I have found in 100 cubic inches ·128 of a cubic inch; in Cumberland mountain water I have found ·281 of a cubic inch; in Loch Katrine water ·113; in Thames water 4·021; and in a deep chalk well water 5·520; so that the variations are very wide.

11,188. (*Mr. Bidder.*) I am asked to clear up one or two minor errors in the table you put in yesterday, with a view of ascertaining the amount of matter in the sewers. I refer to Table B., at page 18; do you observe that you counted one sewer twice over, which raises the average?—No, I did not know that.

11,189. Will you look at the second observation, June the 11th, 1857, Savoy Street; 19·26 mineral, 13·52 organic, total 32·78. Now take the 11th observation, you will find the same figures exactly repeated?—Yes, you are right.

11,190. Now let me draw your attention to another little inaccuracy while we are about it; will you turn to section 4, page 22?—I have it.

11,191. You have one tremendous figure that does great work for you in whipping up the average, namely, that 209·25 at Savoy Street?—But there is another nearly the same below,—210.

11,192. But keep your mind please to the third—you took that from Messrs. Hofmann and Witt?—Yes.

11,193. Are you aware that that figure is not the suspended matter, but the suspended matter *plus* the dissolved matter?—No.

11,194. I think you will recognize the source of your information if I hand this to you (*handing a book to the witness*). I do not find any such figure as that for suspended matter in the authority from which you take it?—I find that the total as given for that day is 296·97.

11,195. That is the suspended matter *plus* the dissolved matter?—Yes, but the figure I have given is 209·25.

11,196. Where did you get your figure of 209 ?—I got it by deducting for dissolved matter, 87·72 grains per gallon, which was found by Hofmann and Witt in the Northumberland street sewage on May 28th, 1857. You will find it in the analytical table on page 14 of their Report.

11,197. Whilst taking these observations for Messrs. Hofmann and Witt, why did you omit certain observations of theirs which give very small results, such as on March the 18th, the Falcon Brook, and on March the 20th, the Earle Brook ?—Those are very minute sewers, I think.

11,198. Are they ? They are two of the largest, I am told ?—The flow is not given.

11,199. (*Chairman.*) Why did you omit them ?—I omitted them because it was obvious that the sewage from these sewers had been subjected to some kind of subsidence before the samples were taken. These samples contained only 3·54 and 2·88 grains respectively of suspended matter per gallon;—proportions which have never been observed in sewage either before or since. The nearest approach to them in the analytical table at page 14 of Hofmannn and Witt's Report is 15·38 grains per gallon in the Fleet sewage bofore rain on April 10th, 1857.

11,200. (*Mr. Bidder.*) Is not there another consideration that would induce you to reject all these earlier observations of the date of 1857, and that is that the London sewage in later years is considerably more diluted than it was in 1857, owing to the increased quantity of water supplied per head of the population ?—It is more diluted. At the same time its character is not changed by merely discharging it at different outfalls.

11,201. But what I mean is this; supposing you had the same amount of road drift coming down in 1857, and only half the quantity of water supplied to the population which is now supplied, you would have twice the number of grains per gallon that you would get now, and if you multiply the number of grains into the doubled supply of water you get a double supply of material brought down ?—Yes, but you are putting it in a tremendously exaggerated form when you put it at double.

11,202. I asked the question because at page 29 of the Rivers Pollution Commission, Third Report, for which, I presume, you are responsible —— ?—For which I am responsible with my brother Commissioners.

11,203. You gave there the sewage of various towns, amongst others, London, and you put this note : "Having given the 1857 observations," and I may say I believe they are the very observations you are dealing with to-day ?—I know that I state that the results of Dr. Hofmann's and Mr. Witt's experiments showed that the sewage was more concentrated at the time than it was when the Report was written, and I attribute that to the larger water supply at the later date.

11,204. "They show, when compared with our more "recent analysis, that the London sewage is now con- "siderably more dilute than it was in 1857" (that was 12 years previously) "owing doubtless to the "increased quantity of water supplied per head of "population" ?—Yes, I agree to that, but the extent of the dilution is given by the chlorine in the sewage in the two periods.

11,205. Because you found 100 grains to the gallon in the old days, in which there was a much less quantity of water supplied to the public, would it be fair to apply that to the much larger quantity of water supplied at the present day ?—Perhaps not strictly so ; it would come out from 90 to 93 instead of 100.

11,206. But surely you had not such a small difference as that in your mind when you used the expression "is now considerably more dilute."

The *Chairman* suggested that the witness should amplify his evidence on this point on a subsequent occasion.

11,207. (*Mr. Bidder to the witness.*) Before I leave the table in your Report I will ask you this : before you got out your grand total of tons of suspended matter, you said you took the rainfall over the 122 miles of the metropolitan area ?—Yes, I so stated it in the Report, 122 square miles of the area of the metropolis and 20 per cent. allowed for the evaporation ; and then again, it is not, as you put it yesterday, that I put these amounts down for the sewage of the 24 hours whilst that sewage might be coming down only for an hour or two. What is done in the table is to attribute to the whole of the rainfall the composition shown by the analysis of a portion of it.

11,208. Less than 20 per cent. of it ?—Yes.

11,209. Included in that, for instance, there are some five or six miles which are the river itself; that is to say, the area represented by the River Thames ; you assume that the rain which falls into the Thames itself brings down 100 grains of grit, or whatever it is, to the gallon ; you have done so, have you not ?—I have not allowed for the area of the river itself.

11,210. Again you have included, have you not, 24 or 26 square miles which are not included in the area drained through the Metropolitan sewers into the River Thames at all ?—I took these figures from the Registrar-General's return.

11,211. (*Chairman.*) You do not know the fact whether or not it is all drained by the metropolitan sewers ?—I am not aware of the facts either one way or the other.

Re-examined by Mr. Lumley Smith.

11,212. I wish to ask you one or two questions upon this important matter as to the extent to which oxidation goes on. My learned friend Mr. Bidder drew your attention to some experiments that were made by Dr. Tidy, and published in the Journal of the Chemical Society, that is so, is it not ?—Yes.

11,213. I believe they were published in the journals of the Chemical Society for May 1880 ?—Yes, they were.

11,214. You were asked one or two questions by my learned friend as to the ground you had for forming an opinion that the results arrived at were not to be relied upon ?—Yes ; I was taken by surprise by that question because I had never thought about these experiments since the time Dr. Tidy and I had this discussion before the Chemical Society.

11,215. When you speak about discussion, a paper of yours was published in the journals of the Society for 1880 ?—Yes.

11,216. Will you tell us, when you say you were "taken by surprise," what reasons you had for forming the opinion that they were not to be relied upon ?—In the first place, I had Dr. Tidy's own statement in which he said "I am bound to acknowledge that the "results showed altogether against my views of oxida- "tion." Then I objected in the next place that those experiments do not represent water running in the river at all.

11,217. The experiment Mr. Bidder said was an experiment of one mile in eight hours ?—Yes, those were the experiments I was alluding to ; they were made in troughs.

11,218. They were made in troughs ten feet long ?—Yes.

11,219. There were 20 of them ?—Yes.

11,220. At the end of each trough there was a fall of some few inches into the succeeding one ?—Yes, and the troughs were lined with pieces of glass.

11,221. After passing through the 20 troughs of ten feet long, the water——

(*Mr. Bidder.*) I think you are not quite fair to Dr. Tidy in quoting that sentence : "I am bound to "acknowledge that the results showed altogether "against my views of oxidation"; because then he goes on to say, "for the following reasons."

11,222. (*Mr. Lumley Smith.*) At the end of the journey the water was received into a cistern, was it not ?—Yes.

*Dr. E. Frankland, F.R.S.*

7 March 1883.

11,223. It was then pumped back into the upper cistern ?—Yes.

11,224. So that in the course of a mile there would be some 26 pumpings or thereabouts ?—Yes, I suppose there would be.

(*Chairman.*) To put it shortly, you objected to the system pursued by Dr. Tidy.

11,225. (*Mr. Lumley Smith.*) That would have an aërating effect in itself ?—Certainly ; it is a very good method of aërating the water.

11,226. The first experiments, it would appear, were made in the open air, and before the troughs were lined with glass ?—I am not aware of that.

11,227. (*Mr. Bidder.*) You say you were not a party to those experiments at all ?—No, I did not see the experiments made ; I had only Dr. Tidy's description of them, and I did not remember that at the time.

11,228. (*Mr. Lumley Smith.*) Having described the nature of the experiment, will you explain how far that is likely to show us the extent of the oxidation ?—In the first place, I imagine that sewage running in this small trough, and presenting, therefore, a very large surface, not merely to the air in proportion to its bulk, but (what is more important) a very large area relatively to the glass sides of the trough, is in a very different condition from the sewage flowing in the Thames when only a very small proportion of the water is in contact with solid matter. I have shown over and over again that water in contact with solid matter, that is to say, water touching a bottom composed of stones or silicious sand, is very rapidly purified ; therefore, I consider that touching the sides of the glass would have a considerable effect in oxidising the sewage flowing through the troughs. Secondly, I believe that the sewage employed was not filtered, but was unfiltered sewage, and if this were so, it could hardly pass through these troughs for the distance it did at the very slow rate of a mile in eight hours without leaving some of the suspended matter either upon the surface of the glass or between the glass and the side of the trough, to which the air would gain access. If that were so, the sewage matter so removed would represent so much sewage matter which had been oxidised according to Dr. Tidy's interpretation of his experiment. In the third place, I believe that some at least of the reduction of the organic elements which Dr. Tidy observed in his latest experiment was due to the decomposition of the urea ; the urea would appear as organic carbon and organic nitrogen, but after it had been decomposed into carbonate of ammonia it would disappear from that result, and would then be so much mineral constituent, which would not be estimated as organic at all. Now, I have proved over and over again, and everybody knows, that urea is very rapidly decomposed when it is in contact with any putrid organic matter, and especially with the residue of previous urine. Everybody knows what an offensive thing a railway urinal is from that cause, and the effect upon the fresh urine of the previous urine is due to the presence of bacteria in the old urine, which immediately propagate at an enormous rate in the fresh urine, and convert the urea into carbonate of ammonia. As soon as the urea is so converted the bacteria all die ; that I have proved by experiment, therefore I conceive that Dr. Tidy fails to produce the effects which at first he attributed to oxidation, because, although at first the nidus for the bacteria, that is to say, the space between the glass plates and the sides of the trough, was not sufficient to develop sufficient bacteria to work upon the urea, yet after the troughs had been in use for a considerable time, and became in a slight degree, I do not mean to the same extent, but in the same condition, as a railway urinal, they generated bacteria which worked upon the urea. That result which he arrived at I conceive to have been partly due to the decomposition of the urea, and only in part to the oxidation. The difference between Dr. Tidy and myself is shortly this,—I say oxidation takes place very slowly, and Dr. Tidy says that it takes place very rapidly, in running water.

11,229. Do those experiments at all alter your view with regard to the River Thames that oxidation takes place very slowly ?—Not in the least.

11,230. (*Professor Williamson.*) With regard to the construction of Dr. Tidy's troughs, you said there were glass plates against the sides of this V-shaped trough ; were they cemented against the trough, or were they placed loosely in it ?—I understood that they were placed loosely in the trough with the edges coming together at the bottom, but Dr. Tidy is here, and he could explain it.

11,231. (*Sir John Coode.*) Dr. Frankland seems to assume that the fluid got ready access between the back of the glass and the trough ; but if it were cemented so that access could not be obtained, that argument would fall to the ground ?—It would so far.

11,232. (*Dr. Stevenson.*) Would bacteria collect in the little inequalities of the river bed ?—I think, if the water in the river were in a putrescent condition, the probability is that the mud of the river would be found to swarm with bacteria.

11,233. (*Mr. Lumley Smith.*) Passing from that, your attention was drawn by my learned friend, Mr. Bidder, to the fact that upon the 22nd of September, at Gravesend, as appears by your Table 12, page 13, there was an absence of ammonia. If you look at Gravesend, you will see that one foot below the surface at low water the amount of ammonia is nothing, and my learned friend, Mr. Bidder, drew your attention to the fact, and asked you whether that did not show, as far as the ammonia test was concerned, that there was no sewage at Gravesend ?—Yes, I was asked that, but I have already explained that the absence of ammonia is no proof of the absence of sewage, while the presence of ammonia is evidence of the presence of sewage.

11,234. In addition to that, I believe you wish to draw attention at the same time to the observation '20 feet below the surface' ?—Yes, I think Mr. Bidder was hardly fair in seizing upon one sample of water as representing the composition of the river.

*Mr. Bidder* objected to the statement, alleging that he had called the attention of the witness to both the samples in question.

(*Witness.*) I wish to say that this sample taken at one foot below the surface was only one of two samples taken at the same time, the other being taken at 20 feet below the surface, so that it would only be fair, I conceive, to give the average of those two samples as representing the condition of the river at that point, that is to say, as containing ·494 of organic carbon and ·149 of organic nitrogen.

11,235. (*Chairman.*) The ammonia is ·060 ?—Yes, but I wish especially to draw your attention to the organic carbon and the organic nitrogen. If we take the mean of these, then we get, as the composition of the water at Gravesend at low water upon the 22nd of September, organic carbon ·350 and organic nitrogen ·125. Now, if we mixed 10 gallons of average London sewage with 90 gallons of pure water, we should get a liquid which would have almost exactly this composition of the water at Gravesend. Now the chlorine determination of the water at Gravesend at this time shows that 54·2 per cent. of it was sea water. The composition of the sea water at high water at Southend (which is the thing I happened to take in this case) was organic carbon ·257 and organic nitrogen ·214, making together ·471, whilst the same organic elements at Gravesend were organic carbon ·350 and organic nitrogen ·125, making together ·475 ; therefore the composition of the sea water as regards organic matter, and of the Gravesend water, is practically identical. We can therefore eliminate the sea water from the result, as it did not make any difference in the result. Now if we take the composition of the water at Erith, the next station above Gravesend, in the same table, at low water, we find that the organic elements in the two low-water samples, taking the

average of the organic carbon and the organic nitrogen at Erith, and adding the necessary quantity of sea water to make a quantity with the same components as that at Gravesend (for there was only a little more than a quarter of the water at Erith at this time sea water, whilst more than half of it at Gravesend was sea water), then the composition of the river water at Erith, calculated from its composition at Gravesend, and allowing nothing whatever for oxidation, would come out carbon ·378 and nitrogen ·142, figures not very different from those found at Gravesend, the mean being there organic carbon ·350 as against ·378 at Erith, and organic nitrogen ·125 as against ·142 at Erith. Therefore I say the composition of the water at Erith confirms to a very great extent the composition of the water at Gravesend; that shows that between Erith and Gravesend, I forget how many miles it is, practically no oxidation takes place.

11,236. (*Mr. Bidder.*) But let me draw your attention to one thing, that, according to your own Table No. 11, the water when it comes over Teddington Weir has a lot of carbon and nitrogen in it, and you have been attributing to sewage that proportion which comes over Teddington Weir?—But you must not assume that the Teddington organic matter cannot oxidise, whilst the sewage organic matter does. If the oxidation took place at the rate you are contending for, then all that organic matter would have been oxidised long before it got to Gravesend.

11,237. (*Mr. Lumley Smith.*) The Teddington element must be eliminated from both?—Yes; therefore you may say that the Teddington water would arrive at the northern outfall as pure water.

11,238. (*Chairman.*) You adopt Mr. Bidder's theory when it is opposed to your views, but your own candid opinion in respect to oxidation is opposed to his?—Yes, only in discussing it I am assuming for the purpose of argument what he assumes, namely, that there is rapid oxidation.

11,239. But you believe that there really is not that rapid oxidation?—Yes, I believe that all the organic matter which comes over Teddington Weir, or very nearly the whole of it, goes past Gravesend.

11,240. Then Mr. Bidder says, that being your opinion, does not that interfere with these calculations?—It interferes to some extent with the proportion of sewage which I mentioned; it would be less than 10 per cent. I do not suppose there would be 10 per cent. present, I was only following out the calculation we should get upon Mr. Bidder's supposition. I do not suppose we should get as much sewage, but there must have been a considerable amount in order to raise the organic nitrogen from ·06 and ·05 to ·149 and ·1.

11,241. (*Mr. Bidder.*) But take the carbon. You will see at Erith it is ·414, at Teddington it is ·321, exactly three-fourths of it?—Yes; of course those are entirely different dates.

11,242. I beg your pardon?—What I mean is that the water coming over Teddington Weir does not get to Gravesend upon the same day or even the same week. I do not think you can fairly represent what is passing Gravesend by what is passing over Teddington Weir.

11,243. (*Dr. Stevenson.*) Does not the amount of organic matter in the water influence the rate of oxidation—Suppose you take two waters, one containing a grain of organic matter and the other ten grains, would they proceed at the same rate of oxidation?—That I am unable to say from any actual experiments I have made; we have the approximate rate of oxidation in the Irwell in the experiments which I gave yesterday, and I have also determined the approximate rate of oxidation in the Thames water in a flow of 4 miles from below Reading to Shiplake Mill.

11,244. Have you made any observations upon this point, that when you have water containing a small quantity of organic matter that is very difficult to remove by oxidation?—I have found that if a water containing a small quantity of organic matter has been subjected for a long time to oxidising influences, it is very difficult to get rid of that. That I conceive to be the condition of the organic matter in sea water which is very difficult to touch, permanganate of potash will not touch it.

11,245. (*Mr. Lumley Smith.*) You have struck out from your table, have you not, some of the observations which you consider abnormal?—Yes, I struck them out because I wanted to get as fairly as possible an average of the composition of sewage under different conditions of rainfall in dry weather, and also with the degrees of rainfall which I give in these tables, and I should consider I have done this very fairly.

11,246. I suppose when you have only a few observations you can hardly take them so fairly as when you have a larger number and take the average?—No, the fewer you have the less valuable your average becomes.

11,247. With regard to Table B can you give me the average, taking in all those which have been ruled out as abnormal?—Yes, I have had calculated for me that average. Taking the whole of the 49 samples—taking into account all those which have been ruled out in my table, the average suspended matter in those analyses is 53·4 grains per gallon—that is under all the conditions of rainfall put together taking all the 49 samples.

11,248. (*Professor Williamson.*) Allowing of course for the relative qualities to which they refer—I mean if you have a great quantity of sewage coming out after a storm and make a computation of the amount of it, do you allow for that?—No, that has not been done in this case.

11,249. You assumed the quantities to be equal?—Yes, I assumed the quantities to be equal—I had not time to take the other out—That would require a day or two. That has been taken out in the table I have produced for each day's rainfall, but to re-calculate the whole upon this basis, I could not do it in the time.

11,250. (*Mr. Lumley Smith.*) What do you mean by the 49 samples?—The 49 samples are I believe the whole of those contained in my table which have been analysed.

(*Mr. Bidder.*) There are far more than 49, are there not?

(*Sir John Coode.*) All that we want to know is the extent to which the average would be affected. If you will endeavour to get us that as briefly as possible that will be all that we shall require.

(*Mr. Lumley Smith.*) I will proceed now to another point. A question was asked you with regard to your section 4, upon page 20. Can you give me from this Report upon the Metropolitan Drainage, 1867, the amount of suspended matter in the Savoy Street sewer?

(*Sir John Coode.*) What you propose to do now is to get us the correct figure?

(*Mr. Lumley Smith.*) The figure I have of the total grains is 209·25.

(*Witness.*) I am referring to page 15 of the Metropolitan Main Drainage Report of 1867. The previous gives the total of the suspended and of the dissolved matter in the Savoy Street sewer.

11,251. If you refer to the next page that takes off the dissolved matter, does it not?—Yes.

11,252. If you subtract the one from the other, that would give you the amount of suspended matter.

(*Mr. Bidder.*) But you are subtracting one thing from quite another—you are substracting the mean of a number of days from the result of a particular day which is a very abnormal day.

*The Chairman* intimated that the witness should be allowed to go into the calculation at leisure.

11,253. (*Mr. Lumley Smith.*) You were asked about the catch pits in the metropolis. You have made experiments about catch pits both in the metropolis and in the country, have you not?—I have not made actual experiments to ascertain what proportion of the suspended matter is carried into the sewers and what remains in the catch pits.

*Dr. E. Frankland, F.R.S.*

7 March 1883.

11,254. You gave us an opinion that a very small proportion is caught in the catch pits. From what did you derive that opinion?—My experience was from observing what is caught in sewage tanks. If you have a stream of sewage running through a tank whilst a storm is going on, there would be very little deposit take place there. The Rivers Pollution Commission mentioned that very specially in their Report upon Mining.

11,255. (*Sir John Coode.*) You mean the agitation is so great that very little will fall?—Yes, it requires almost entire rest to get anything like perfect subsidence.

11,256. (*Mr. Lumley Smith.*) You are aware, are you not, how the catch pits in the metropolis are made?—Yes.

11,257. You stated that the taking of the samples at the outfalls, was stopped at the time of heavy rainfall, so that you had a difficulty in getting the amount of suspended matter in times of heavy rainfall. You say, with regard to Mr. Keates's observations, that they ceased in times of heavy rainfall?—I said they ceased, but why, I did not know.

11,258. How are they recorded?—They are recorded in the report to the Metropolitan Board of Works which was produced at the former inquiry. I have not got it with me, but I entered the results in a table in my report from that report of Mr. Keat's observations.

11,259. You are dealing with what is published in that report?—Yes.

11,260. (*Chairman.*) What observations are you referring to?—Those marked on pages 18, 19, and 20 of my own Report with two asterisks.

11,261. (*Mr. Lumley Smith.*) Do you know what report you got that from?—I think it was published some time in 1880.

11,262. You were asked whether, according to your calculations, you were not showing (I think my learned friend Mr. Bidder put it) that about seven times as much, would have to go into the sewers as they would hold?—Yes, I think Mr. Bidder objected to my assumption, suggesting that the whole of the rainfall when it was on one occation 3,676,000,000, or 2·5 inches, could not possibly get into the Thames through the sewers; and I said I could not conceive any other way in which it could get into the river, except through the sewers.

11,263. (*Chairman.*) Have you any observation to make upon that?—Yes, I have, in the meantime, an extract from the report of Sir Joseph Bazalgette which throws some light upon that matter. This is Sir Joseph (then Mr.) Bazalgette's report upon the source of the Kent drainage, "To the Honourable the Metropolitan Commissioners of Sewers," with respect to the Greek Street sewer 1853.

(*Mr. Bidder.*) But the sewers were not made then.

11,264. (*Chairman.*) You say there is some observation of Sir Joseph Bazalgette which seems to throw some light upon this question of the 3,676,000,000?—Yes, I think it does. Sir Joseph Bazalgette says: the largest quantity of rain which fell in London in one day during the wet season of 1852 measured 1½ inches, but storms amounting to 2½ inches in a day, although of rare occurrence have been recorded, and these would deliver into high level sewer (Sir Joseph Bazalgette is speaking now of the drainage scheme which was then under consideration) 45,000 cubic feet per minute which it is capable of discharging upwards of 46,000. The low level sewer will discharge 21,400 cubic feet per minute, and it is here proposed that the existing main sewers in the low districts should act as reservoirs during such extraordinary storms. From their construction and the remarkable flatness of their level, they are peculiarly adapted to this object and it is estimated that on these occasions, they would store the surples floods without the rising of the latter to an inconvenient height, and would again deliver their contents into the Thames low water, or intercepting sewer as it became free to receive them. Thus the provision of engine power for such rare occasions would be saved, and the existing sewers made available. The next extract is from a report by Sir Joseph Bazalgette submitted to the Metropolitan Commissioners of Sewers on January 22nd. 1855. "In those portions of "the district where drainage outfalls are required in "addition to the interception of sewage, provision for "storm waters becomes necessary, and for districts of "the extent, level, and general character of those "now under consideration, the main outfall sewers "should be capable of discharging 2½ inches of rain "in 24 hours, as is more fully set forth in my report "upon the southern drainage, and with the exception "of this difference, their dimensions have been calcu-"lated as already explained." So that he says that "2½ inches can be discharged," and that was the rainfall I have named.

Examined by the Commission.

11,265. (*Dr. Stevenson.*) I wish to ask you about the red worms; I do not know whether we quite understand you about the red worms found in the Thames. You spoke of them as being characteristic of the sewage?—Yes, I consider them chacteristic of the sewage. I have never found them except in mud that has come from a sewer.

11,266. You have never found them for instance in the higher hills of Surrey, and in ponds with vegetable matter only in them?—No.

11,267. Then how do you account for their disappearance from this part of the Thames; we have it in evidence that they were formerly abundant at Hungerford Bridge?—That was just at the outfall of the Northumberland sewer which came out through Scotland Yard, and entered the river at Hungerford Bridge.

11,268. But why have they disappeared and gone lower down the river; how do you account for that?—My observations have shown me that the worms have disappeared from Hungerford Bridge, and have appeared lower down the river.

11,269. (*Chairman.*) One witness stated that there were none of these worms?—I found them in several places, three years ago, when I was inspecting the river for the Thames Conservancy Board.

11,270. (*Professor Williamson.*) You found them in places where there was a sewage deposit?—Yes.

11,271. (*Sir John Coode.*) Your idea is that the worms follow the sewage?—Yes.

11,272. That is the very reverse of the evidence which was given by the fishermen who say they have disappeared from where they used to find them.

11,273. (*Dr. Stevenson.*) With regard to the urea, I think we have it in evidence, that a considerable quantity of urea would reach the outfalls; Do you find any quantity of urea in the Thames or in the neighbourhood of the outfalls when the sewage is being discharged?—I have never found it in the Thames, but I cannot say that I ever looked for it;—it is not a very easy thing to detect in polluted liquid.

11,274. Have you formed any opinion as to whether much of it would reach the Thames?—Yes. I think a considerable portion of it would reach the Thames, and, once mixed with a large quantity of fresh water, I believe its destruction proceeds then very slowly. From experiments which I have already described to the Commission as to the mixing of urine with the Kent Company's water, I found that the urea was decomposed with extreme slowness when it was mixed with a large quantity of fresh water.

(*Professor Williamson.*) There were no bacteria to do it?—No, they could not live in so dilute a solution. Dr. Stevenson asked me, I think, yesterday, about organic matter being very rich in nitrogen; there is guanine containing one part of nitrogen to ·857 of carbon—guanidine contains one part of nitrogen to ·285 of carbon—allantöin contains one part of nitrogen to ·857 of carbon—urea contains one part of nitrogen

to ·428 of carbon, and uric acid one part of nitrogen to 1·07 of carbon. Those are all substances which may be present in sewage especially the urea which we know is present and guanine is a thing which is likely to be present in sea water.

11,275. They are all products of the decomposition of urine?—Yes.

11,276. (*Dr. Stevenson.*) You know of no bodies other than those produced by the decomposition of urine which would give that result?—No, I think not.

*Er. D. Frankland, F.R.S.*

7 March 1883.

The witness withdrew.

Dr. CHARLES MEYMOTT TIDY, recalled and further examined.

11,277. (*Chairman.*) What do you wish to say about the troughs used in your experiment to which reference has been made?—All the troughs were very carefully washed out before the analysis was made. I have no reason to believe there were any leakages between the glass slides and the sides of the trough. The glass slides were very accurately ground and they were cemented to the wooden troughs with cement.

11,278. (*Sir John Coode.*) Did you notice any matter attaching to the glass after the experiment?—I did not. I must say that the experiments occupied something like seven months, and a place was taken specially on purpose to carry them on.

11,279. You did examine the glass to see whether there was any foreign matter attaching to it?—Yes, certainly. And with regard to a remark of mine that a great many of the results went against the theory of oxidation, I should explain that it was done out of doors. It was a very large apparatus, and it was very difficult to keep the blacks out, and it was not until I had adopted a very large number of devices to keep the blacks out, that I got any reliable results. I think it is right to explain that it went against my views on account of the blacks getting into the troughs.

*Dr. C. M. Tidy.*

The witness withdrew.

Professor JOHN THOMAS WAY, F.C.S., called in and examined.

11,280. (*Mr. Balfour Browne.*) You are a consulting chemist, a Fellow of the Chemical Society, a Fellow and Member of the Council of the Institute of Chemistry, and were formerly Consulting Chemist to the Royal Agricultural Society?—Yes.

11,281. And you were also, I think, one of the members of the Royal Commission on Sewage?—Yes, Lord Essex's Commission.

11,282. That Commission sat, I think, in the years 1857 to 1865?—Yes, it sat for eight years.

11,283. You also acted upon the first Royal Commission with respect to Rivers Pollution, did you not?—Yes.

11,284. That Commission, as the Commissioners know, reported upon the Rivers Thames, Lea, and so on?—Yes.

11,285. You have had a very lengthened experience in relation to water supply and sewage?—I have.

11,286. Have you got beside you the results of the determinations of chlorine in the samples of water collected in the Thames and examined by you?—I have.

11,287. (*Chairman.*) You did examine certain samples?—I have examined a great number of samples.

11,288. (*Mr. Balfour Browne.*) Your table is at page 5 of the blue tables that were handed in by Mr. Baldwin Latham. I think what was handed in by Mr. Baldwin Latham was a resumé of the whole of your experiments, and you are now going to hand in the particular determinations of the samples submitted to you?—If you allude to the pamphlet by Mr. Baldwin Latham, I think it was a resumé of the first set of samples that were examined, but I think it would be better if you would allow me to put them in the form in which they were delivered, which is really that of date.

(*Chairman.*) We have, at all events, this resumé laid before us.

(*Mr. Balfour Browne.*) You have only two columns of the resumé.

(*Chairman.*) These tables represent, in fact, the work of Professor Way, and what you want to ascertain from Professor Way is, that he did make these analyses and that they are correct.

(*Witness.*) Yes, but I wish, if I may be allowed, to put in the full particulars.

*The same were handed in and were as follows.*

*Prof. J. T. Way, F.C.S.*

DETERMINATION OF CHLORINE IN SAMPLES OF THAMES WATER.

No. 4.

| | Samples from Grays. Collected 22nd December 1882. | Chlorine in 100,000. |
|---|---|---|
| 1 | "Green Man and Bell," 11.30 a.m. Well 20 feet deep. | 14·0 |
| 2 | "The Dell." Mr. . Well 100 feet deep. Short way out Grays. 12.30 p.m. | 2·5 |
| 3 | Sockets Heath Cottage. Well 104 feet deep. 1.30 p.m. | 3·6 |
| 4 | The College, Little Thurrock. Well 90 feet deep. 2.15 p.m. | 13·0 |
| 5 | Brewery, Grays. Half tide, 10.15 a.m. | 9·7 |
| 6 | Ditto High tide, 12 noon | 9·7 |
| 7 | Ditto Low water, 3.45 p.m. | 9·7 |
| 8 | South Essex Waterworks. Half tide, 9 a.m. | 13·3 |
| 9 | Ditto High water, 11.15 a.m. | 13·6 |
| 10 | Ditto Low water, 3.45 p.m. | 13·4 |
| 11 | Grays Chalk Quarries. Half ebb, 9 a.m. | 3·9 |
| 12 | Ditto High water, 12 noon (?) | 4·2 |
| 13 | Ditto Low water, 3.50 p.m. | 4·2 |
| 14 | River Thames off "Exmouth." Half tide, 9 a.m. | 507·5 |
| 15 | Ditto High water, 11 a.m. | 635·0 |
| 16 | Ditto Low water, 3.45 p.m. | 475·0 |

| | Samples from Wells at Erith. Taken December 30th, 1882. | |
|---|---|---|
| 11.30 a.m. | Pump well near the river, just above Beadle's Coal Wharf. | 3·8 |
| 11.30 a.m. | Pier head (river) at low water - | 40·5 |
| 12.30 p.m. | Well at 21, Pier Road, about 120 feet deep. | 3·6 |
| 12.35 p.m. | Well at Crown Cottages (?), Cross Street, leading out of Pier Street. Well very deep. | 10·8 |
| 1.30 p.m. | Well at Crayford Road, North End Cottages, about 1¼ to 1½ miles from pier. Well about 120 feet deep. | 5·6 |
| 1.40 p.m. | Well in same road, opposite side, about 200 to 300 north-east, about same depth as last. | 1·4 |

(*Witness.*) The first table is a table of samples collected on September the 14th and September the 22nd. I do not know whether the Commission know how these samples were collected, because if that has not been described it certainly ought to be described now.

11,289. (*Chairman.*) You did not collect them?—No, I did not collect them; they were merely brought to me.

11,290. Did you determine the mode in which they should be taken?—No.

11,291. Do you approve of the mode in which they were taken?—Yes; but unless that mode has been described to the Commission it should be described.

(*Chairman.*) We have not had the witness who took the samples. Dr. Tidy took some of the samples himself.

(*Mr. Bidder.*) As I understand Professor Way, he is not at all responsible for the taking of the samples; certain samples were brought to him labelled.

(*Mr. Balfour Browne.*) If it is necessary we can prove the taking of every sample.

(*Mr. Bidder.*) It is necessary.

(*Mr. Balfour Browne.*) What I want to bring before the Commission now is the method of taking the samples by description.

(*Mr. Bidder.*) But that will not prove the samples, because Professor Way did not take them.

(*Chairman.*) He is going to say that, assuming the samples were taken in the way he is going to describe, that was the proper way of taking them.

(*Mr. Bidder.*) But did he give the instructions as to the way in which they should be taken.

11,292. (*Chairman.*) No he did not. (*To the witness.*) You were told how the samples were taken?—Yes, it was in rather a lengthy way, but it ought to be given, if the Commission are to understand the value of the tables.

11,293. Will you give us the way in which you were informed the samples were taken?—I will; in fact I was informed of it by Dr. Collingridge, who had the responsibility of seeing that the samples were taken properly, but Mr. Balfour Browne will understand that I did not know whether this information had been given yet.

(*Mr. Balfour Browne.*) I do not think that the method of taking the samples has been given.

(*Witness.*) Do you propose to give it?

(*Mr. Balfour Browne.*) I thought you said it was important it should be given.

(*Chairman.*) Will you state how it was described to you that they were taken.

(*Mr. Bidder.*) But that is not evidence. The person who really took the sample must describe how it was taken, but what you put is a very legitimate question. If that sample was taken in such a way, was that properly taken.

(*Chairman.*) Quite so, and the witness will then say that if the samples were taken in such and such a manner, that was a very proper manner in which to take them.

11,294. (*Mr. Balfour Browne.*) (*To the witness.*) Will you describe how the samples were taken?—You will notice that in the first half of the first sheet, the localities, Teddington, Chiswick, St. Paul's Pier, and so on are named; those were 10 stations upon the river that were selected as places at which to take the samples, the object being to ascertain how far, and under what circumstances, the sea water, as indicated by the chlorine, went up the river. These 10 stations are from Teddington to Southend; at Teddington, as a matter of course, the water flowing over the weir would not be subject to tidal influence, but the sample taken at Teddington was below the weir, and therefore it is the last point of the river to which sea water could have access. The samples were taken, in some cases three samples, and in other cases five samples, at certain equal distances across the river; the object being to ascertain whether there was any difference in the flow of the tidal water. They were also taken at one foot from the surface, and in some cases as near the bottom as possible, and in other cases at 20 feet deep. In the upper reaches, at low water especially, there was not enough water to take them at 20 feet deep, but wherever 20 feet depth of water could be obtained a sample was taken at 20 feet. Then a sample was taken on high tide and low tide, so that wherever there are five stations across the river, we have 20 samples at that particular spot, 10 of which were taken at high tide and 10 at low tide. As I say, I have no responsibility and equally no credit for the method of collection, but the object is obviously to avoid any differences which were not due to the motion in the river from its source.

11,295. (*Chairman.*) You think that the manner of collection is correct?—I think it is admirable; it involved an amazing deal of trouble, but at the same time there can be no mistake as to the result.

11,296. (*Mr. Balfour Browne.*) Now just taking Teddington first, that first determination 1·8 represents the result of five samples, does it not?—No; this is exactly why a full description of our method is necessary, that represents one sample only.

11,297. I see the whole of the samples are put under each other?—Yes.

11,298. So that there was a separate analysis for each sample?—There was a separate analysis for each sample.

11,299. I think it may be as well to point out that the letter "A." always begins upon the south shore of the river?—Yes.

11,300. And that the other letters stretch across the river to the north shore?—Yes.

11,301. (*Chairman.*) The blue printed table which is taken from Mr. Baldwin Latham's pamphlet, gives the net results of your analysis, does it not?—Yes, only I thought it necessary that you should know how the net results had been got out; indeed it is absolutely necessary, because it sweeps away, as we believe, the possibility of error due to difference of position in the river, and depth from which the sample was taken in the river.

11,302. (*Chairman.*) Are there any further remarks that you wish to make with respect to the details?—No, I think not, except that the second table called "Resumé," is the result of the averages of these others.

11,303. (*Mr. Balfour Browne.*) But before we get to the second table, upon this first table, there are two sets of determinations in relation to a spring tide upon the 14th of September, and a neap tide upon the 22nd?—Yes.

(*Sir John Coode.*) All these are in the blue paper.

11,304. (*Mr. Balfour Browne.*) But there is the 30th of November 1882. (*To the witness.*) Have you the set of determinations for that?—I have; that has been handed in with the others.

11,305. Amongst those documents that you have handed in, there are various other tables, No. 1, No. 2, No. 3. and No. 4; what are those?—Those are other analyses of water for chlorine which were or have been used, I dare say, in this inquiry.

11,306. Those analyses were made by you from the water supplied in the same way as you have described?—Yes.

11,307. Will you now state briefly the evidence you are prepared to give?—First of all I cannot expect, nor would it be right, that the method in which this analysis has been made should pass without animadversion, or at all events inquiry; therefore I wish to say something about that. Now, as a rule, the analysis for chlorine is one of the easiest things imaginable, and I do not say it is otherwise than easy in this case; but it is not as a rule that chemists have to deal with sea water, that is to say, with water containing very large quantities of chlorine. The analyses of sea water have been, perhaps, the most neglected of all kinds of water. Now there are two methods of analysis for chlorine, one the old or gravimetric method, in which the chlorine is collected as chloride of silver and weighed; another method is the method of determining it by volume, that is to say by a colour test—that is known as the volumetric method; the one is much easier and takes up much less time than the other, and it is natural in cases where a large number of analyses were to be made that one would take a method which would enable him to get more readily the results, consequently the volumetric method was taken; but I found that as there was so much work to do, it was necessary one should be quite safe of one's facts before one commenced, and I found in determining the salt in sea water, or water at Southend, or anywhere near the sea, where large quantities of salt were, that the ordinary method in the first place did not give correct results as usually

*Prof. J. T. Way, F.C.S.*

7 March 1883.

worked—that is to say, there were some 2 or 3 per cent. of difference in the chlorine in the actual result, when the usual strength of silver test was employed.

11,308. (*Prof. Williamson.*) Are you now speaking of the gravimetric method?—I am speaking now of the volumetric method, although even in the gravimetric method the determination of large quantities is liable to considerable error owing to some difficulty of measuring.

11,309. Have you pursued one method all through?—I have checked them; these are mainly made by the volumetric method.

11,310. (*Sir John Coode.*) But you have taken every step to satisfy yourself of the accuracy of the result?—Yes. I do not wish to give a lecture on chemistry, but I say now, as the result might perhaps be questioned when one was not here to explain it, that it is extremely difficult to get accurate results within 1 or 2 per cent. of the whole chlorine from these waters, which contain large quantities of salt; but then as a matter of course, where larger quantities of salt are, the less the little variations matter. The chemical members of the Commission will know, of course, that we cannot take large quantities of a solution of salt for this purpose, but we must have a small quantity, and we can only get that small quantity by dilution and sub-measurement, not by taking very minute quantities; it is not possible to get them near enough. I believe these results are within 1 or 1½ per cent. of the total chlorine present, that is, of the total common salt present, so that a quantity which would stand in these tables as 1,000, for instance, might be 1,010, or it might be 990; but that would make no real difference, and that is my object, to show that that difference is not material.

11,311. (*Mr. Balfour Browne.*) Have you any further remark to make with regard to the method of making the analyses?—I think that is all that it is necessary to say.

11,312. Now I will ask you one question with regard to what fell from another witness. These determinations show the quantity of chlorine in the cross-section taken across the river?—Yes.

11,313. And you find, do you not, that the quantity of chlorine varies very little either across the river, or by reason of depth?—No; and that is very important. I have omitted to say that there is very little difference in the samples as taken across the river, or as taken at 1 foot from the surface, or taken deep.

11,314. (*Sir John Coode.*) Which the tables show?—Yes, which the tables show; and this resumé is deduced from these tables, the consequence is that the resumé may fairly be taken as proving the state of the river.

11,315. (*Mr. Balfour Browne.*) Is there a greater difference between the samples taken at the surface and those taken 20 feet down?—There is a greater difference; it is not a great difference, but it is a more general difference.

11,316. This resumé of yours, which you have handed in, and which is before the Commission, is, I think, the mean of all the experiments that were shown upon the other tables?—No, it is the mean of the experiments shown upon the first table.

11,317. You have a similar series of observations as to the 30th of November, except that on the 30th of November they were not taken across the river because there had been found to be no difference arise from taking them across the river?—Yes, they were only taken at one point upon the river instead of being taken across the river; but they were taken even in that case shallow and deep.

11,318. (*Mr. Bidder.*) It is not quite correct to say that there was no difference, because the tables show that there were considerable differences?—Yes, there were differences, but the differences were so much less than the differences at the different stations that it was not worth while taking them in so many places.

11,319. You cannot tell us, I suppose, what part of the river they were taken from upon the last occasion?—No, except from general knowledge.

(*Sir John Coode.*) Would not those differences be accounted for by the quantity of fresh water in the river?

(*Mr. Bidder.*) No doubt that accounts for there being less chlorine generally, but that is not the point.

11,320. (*Dr. Stevenson.*) Would you allow me to direct your attention to one matter. You heard the question I put to the previous witness with regard to the decomposition of urea. I believe you have made some experiments upon that subject, and before you come next before us you would perhaps be able to give us some information as to the rate at which urea decomposes in sewage?—It decomposes at a very great pace. In London sewage you can never find urea.

11,321. You have never found it?—No.

11,322. (*Mr. Bidder.*) You mean it is all gone before it gets out of the sewers?—Yes, but urea is not carbonate of ammonia you will recollect.

11,323. (*Dr. de Chaumont.*) Have you made any experiments as to how soon putrefaction sets in in sewage?—I cannot say that; not to give any definite idea.

11,324. (*Sir John Coode.*) The urea disappears as urea, but it takes up some other form?—It becomes carbonate of ammonia; but what I mean to say is that the urea is so evanescent that you must never expect to find it in sewage. Urea is one of the most easily changed matters imaginable; by any organic matter passing into it, it is changed almost immediately.

(*Mr. Balfour Browne.*) It will be understood that Tables 1, 2, 3, and 4 are proved by Professor Way.

*Mr. Bidder* stated that he had no questions to ask the witness at present in cross-examination.

The witness withdrew.

Professor Charles William Heaton, F.I.C., F.C.S., called in and examined.

*Prof. C. W. Heaton, F.I.C., F.C.S.*

11,325. (*Mr. Lumley Smith.*) I believe you are a Fellow of the Institute of Chemistry?—I am.

11,326. And a Fellow of the Chemical Society?—Yes.

11,327. You are also Lecturer on Chemistry at the Charing Cross Hospital?—I am.

11,328. And you are also one of the Examiners in Chemistry to the Royal College of Physicians?—Yes.

11,329. I believe you reside in the neighbourhood of Erith?—Yes, I do.

11,330. Are you often on the river?—Yes.

11,331. How long have you known the river in that way?—I have known the river, to a certain extent, for the last 20 years, but it is only in the last few years that I have been frequently upon the river.

11,332. (*Chairman.*) Within what time?—I should say within the last five or six years I have been sailing occasionally upon it.

11,333. (*Sir John Coode.*) How near is your house to the river?—About a mile, or a mile and a half. I am in Erith parish, but not in the immediate neighbourhood of the river.

11,334. (*Mr. Lumley Smith.*) Now I will ask you generally, have you at any time found anything unpleasant in the condition of the river?—Yes, I have observed disagreeable smells.

11,335. Is that at any particular time, or all the year round?—In hot weather only.

11,336. Where do the smells come from?—I have distinctly smelt a disagreeable smell from the river, but still more frequently from the mud; and certainly from both in hot weather.

11,337. Have you found that increase or decrease of late years?—I cannot say for certain upon that point. I believe Professor Tuson is more experienced than I am upon the river, and he will be able to speak to that.

11,338. In cold weather can you at any time detect smells?—Yes, when very near the outfalls.

11,339. How far off from the outfall?—I have smelt it even in cold weather I think I may say safely at a distance of one mile when the wind has been from that direction.

11,340. But in very hot weather how far have you detected the smell?—In very hot weather I have smelt the smell of the water miles away. It has come down upon the wind.

11,341. It is not a smell perceptible upon the water only, but a smell that has come down upon the wind itself?—Yes.

11,342. (*Sir John Coode.*) Did you smell it last summer?—I smelt it very slightly.

11,343. Was that on account of the wetness of the weather and the cold?—Yes.

11,344. (*Mr. Lumley Smith.*) Now you smell these smells in cold weather?—Yes, upon the river.

11,345. Do you detect them upon the shore?—No, I cannot say that I can detect them there.

11,346. (*Mr. Bidder.*) When you say you smelt the river miles away, what do you mean; do you mean miles away from the river?—No, I mean miles from the outfall.

11,347. (*Mr. Lumley Smith.*) What are the prevailing winds at Erith that would carry the smells from the outfall itself?—The winds that would carry the smell you would see, I think, by the map, are north, north-west, and north-east, but not the southerly winds, or the south-westerly winds.

11,348. The former are usually cold winds?—Yes, I think they are.

11,349. So that at the time when the smell would come from the outfall would be the time when the weather is cool and the winds are cold?—I think so.

11,350. Those winds which prevail in the summer months would mostly blow the other way. Now you have not only given attention generally in this way to the water, but you have made a series of experiments upon the water?—Yes, with Professor Tuson.

11,351. I believe he also lives near Erith, does he not?—Yes, he does.

11,352. Will you tell us generally, before I come to details, the nature of the experiments you have made with the water?—We have made a certain number of analyses of the water, taking special points which seemed to us to be likely to be valuable. Of course our experiments have been by no means so extensive as those of the chemists who have given evidence, but we tender them because we think there have been some points of importance proved by them.

11,353. (*Sir John Coode.*) When you say "of "importance," you mean with regard to the composition of the water?—Yes, I think so.

11,354. (*Mr. Lumley Smith.*) You have taken samples, as I understand?—Yes, we have taken samples ourselves.

11,355. And you have tested the samples?—Yes.

11,356. For what purposes, and in what way have you tested the samples; first of all have you tested them for the purpose of finding out what component parts there are in them, what are the things you have tested for?—We have tested for certain constituents.

11,357. Will you tell us the particular constituents for which you tested?—Those which appeared to us to be most important are two in number, first the examination of what is called albumenoid ammonia, and, secondly, the determination of dissolved oxygen.

11,358. Those are the two important ones?—I do not say that they are the only important ones, but we regarded them as very important for our special purpose.

11,359. You have tested for those two things, have you tested for anything else?—Yes for certain other constituents; we have made a certain number of determinations of nitrates on special occasions.

11,360. Will you tell us, first of all generally, between what dates you made your experiments?—The experiments began in July, and were made at intervals as the time at our command allowed through the greater part of the rest of the year.

11,361. I believe you have prepared some tables of which you have a copy before you?—Yes, this is a table (*producing the same*), giving three constituents only, and of those only one appears to me to be of special importance to the Commission, one of them is a determination of the free ammonia. You have heard so much about free ammonia, that I apprehend the Commission would scarcely care to have more evidence upon that matter: there is ammonia in the river, and I daresay you do not care to hear more about it, the figures are very irregular, and I do not profess to found much upon them; they tend to show that the river is polluted, and polluted with sewage, but I do not apprehend that that will be doubted.

11,362. (*Sir John Coode.*) It is a question of extent?—Yes, I do not pretend to be able to speak to the extent of the pollution from ammonia. I think our determinations about the albumenoid ammonia do give results of some interest. This table, which I will hand in, shows the parts per 100,000 of free ammonia, oxygen absorbed, and albumenoid ammonia.

(*The same were handed in, and were as follows.*)

*Prof. C. W. Heaton, F.I.C., F.C.S.*

7 March 1883.

## THAMES POLLUTION.

| Number of Sample. | Date (1882.) | Where taken. | I. Parts of Free Ammonia in 100,000 of Water. | | | | II. Parts of Oxygen absorbed in 100,000 of Water. | | | | III. Parts of Albumenoid Ammonia in 100,000 of Water. | | | | Remarks. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | High Water. | Low Water. | Flood. | Ebb. | High Water. | Low Water. | Flood. | Ebb. | High Water. | Low Water. | Flood. | Ebb. | |
| 1 | July 8 | Off Purfleet: in tideway. | — | — | ·0264 | — | — | — | ·6280 | — | — | — | ·0921 | — | Water very black. |
| 2 | Do. | About half a mile below Crossness: in tideway. | ·0534 | — | — | — | ·3000 | — | — | — | ·0434 | — | — | — | Much seaweed. |
| 3 | Do. | Twenty yards above Crossness Outfall; half an hour before high water: close to South Shore. | ·2789 (Not included in average.) | — | — | — | 2·200 (Not included in average.) | — | — | — | ·2785 (Not included in average.) | — | — | — | Sewage distinctly seen to be flowing up stream; bad smell in air; one engine at work at pumping station. |
| 4 | July 17 | Off Crossness: midstream. | ·0494 | — | — | — | ·3160 | — | — | — | ·0538 | — | — | — | Engine at pumping station not at work. |
| 5 | Do. | One mile above Barking Outfall: midstream | ·0680 | — | — | — | ·3640 | — | — | — | ·0688 | — | — | — | |
| 6 | Do. | Off Crossness: same place as No. 4, but about two hours later. | — | — | — | ·0549 | — | — | — | ·5320 | — | — | — | ·1183 | In full stream of sewage from Barking, but not from Crossness; foul smell in air from north shore. |
| 7 | Do. | Between Crossfield's and Belvedere Guano Company's Works: midstream. | — | — | — | ·0070 | — | — | — | ·4800 | — | — | — | ·1140 | In line of Barking, but out of line of Crossness sewage. |
| 8 | Do. | Between Corinthian Yacht Club and Post on North Shore: midstream. | — | — | — | ·0324 | — | — | — | ·4880 | — | — | — | ·0800 | In line of sewage from both outfalls. |
| 9 | July 25 | Same as No. 8. - | — | — | — | ·0875 | — | — | — | ·3914 | — | — | — | ·0518 | |
| 10 | Do. | Off the "*Cornwall*": midstream. | — | — | — | ·0264 | — | — | — | ·3217 | — | — | — | ·0399 | |
| 11 | Do. | Off Greenhithe: between the "*Worcester*" and the "*Shaftesbury.*" | — | ·0320 | — | — | — | ·3280 | — | — | — | ·0462 | — | — | |
| 12 | Do. | Same as No. 11 - | — | — | ·0050 | — | — | — | ·4380 | — | — | — | ·0804 | — | |
| 13 | Do. | Same as No. 10 - | — | — | ·0180 | — | — | — | ·2800 | — | — | — | ·0319 | — | |
| 14 | Do. | Same as No. 8 - | — | — | ·0044 | — | — | — | ·3960 | — | — | — | ·0843 | — | |
| 15 | August 1 | Off Corinthian Yacht Club. | — | ·1955 | — | — | — | ·4400 | — | — | — | ·1039 | — | — | Middle of eddy, near South Shore-water of brown colour and smelt strongly of sewage. |
| 16 | Do. | Off Corinthian Yacht Club: between edge of eddy and North Shore. | — | ·1544 | — | — | — | ·4357 | — | — | — | ·0889 | — | — | Colour not quite so bad, and smelt similar to, but not nearly so bad, as No. 15. |
| 17 | Do. | Same as No. 16: in heart of tide. | — | — | ·1188 | — | — | — | ·4960 | — | — | — | ·1617 | — | Colour lighter than No. 16; odour slight, but distinctly offensive. |
| 18 | Do. | Same as No. 16: midstream. | ·0030 | — | — | — | ·4960 | — | — | — | ·1044 | — | — | — | Colour much better than last sample; no bad smell. |
| 19 | Do. | Same as No. 16: heart of tide. | — | — | — | ·0274 | — | — | — | ·2400 | — | — | — | ·0419 | Colour slight; no bad smell. |
| 20 | Do. | Same as No. 19 - | — | — | — | ·1272 | — | — | — | ·4800 | — | — | — | ·0949 | Colour dark brown; odour not bad. |
| 21 | Do. | Same as No. 19 - | — | — | — | ·0051 | — | — | — | ·4800 | — | — | — | ·1119 | Colour dark brown; odour sewage-like; rather bad. |
| 22 | August 7 | About 1 mile below Jenningtree Point, and about 200 yards from South Shore. | — | — | — | ·0219 | — | — | — | ·5360 | — | — | — | ·1487 | In strong eddy; smell of sewage in water. |
| 23 | Do. | Off Jenningtree Point: midstream: heart of tide. | — | — | — | ·1979 | — | — | — | ·4760 | — | — | — | ·1009 | Sewage smell in water. |
| 24 | Do. | Just below Little Cold Harbour Point: about 200 yards from North Shore. | — | — | — | ·0424 | — | — | — | ·5400 | — | — | — | ·1827 | Very dirty; sewage smell. |

| Number of Sample | Date (1882.) | Where taken. | I. Parts of Free Ammonia in 100,000 of Water. | | | | II. Parts of Oxygen absorbed in 100,000 of Water. | | | | III. Parts of Albumenoid Ammonia in 100,000 of Water. | | | | Remarks. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

* There is no evidence as to the collection of this sample.

11,363. Now passing to the subject of the albumenoid ammonia, have you any remarks to make with regard to the samples that you took?—Yes; may I explain why we use that particular method.

11,364. Will you proceed to do so?—We use that method because we think that it does give evidence with regard to the organic matter capable of putrefaction that is present in the water. The bad smells that we have observed are in our opinion due to the putrefaction of nitrogenous matter in the water, and for that purpose it was desirable to get some kind of measure of the quantity of such albumenoid matter. Now the organic nitrogen determination is of the greatest value, but it is to a certain extent reduced in value in an inquiry like this, by the fact that sea water contains much organic nitrogen. Now it is perfectly well known to us, as it is I believe to all other chemists, that the albumenoid ammonia estimation only represents some fraction of the nitrogenous putrefialbe organic matter.

11,365. (*Prof. Williamson.*) You mean the determination by permanganate?—Yes; but I believe it is pretty well agreed that in a river like the Thames albumenoid ammonia does come from nitrogenous organic matter of some kind. Certainly the experience of every chemist who has worked by this method is that you get much albumenoid ammonia from bad polluted water and very much less or none at all from unpolluted water.

11,366. (*Chairman.*) Why do you say in "a "river like the Thames"?—Because I can imagine that the test would have a different value if it applied to other rivers, as for instance, a river highly impregnated with peat. I have no experience of how it would happen elsewhere, because our experiment only applied to the Thames, and I should not like to give it as to other rivers. In the river Thames it appears to me that the albumenoid ammonia must come from nitrogenous organic matter capable of putrefaction.

11,367. (*Mr. Lumley Smith.*) Did you use for the purpose of your experiment filtered or unfiltered water?—Unfiltered water.

11,368. Will you explain why you did so?—Because

*Prof. C. W. Heaton, F.I.C., F.C.S.*

7 March 1883.

we believe that the river smell is due to putrefaction. Now, the nitrogenous organic matter in the water would be partly in solution and partly in suspension; it appeared to us that it did not matter in which condition it was; the question was whether it would putrefy and smell, and as the water was unfiltered we thought that it would be better to make our experiments in the water as it stood, so that they should represent, as far as they were able to do, the actual condition of the river. Whatever albumenoid ammonia we got must have been derived from some quantity of nitrogenous matter; we cannot say exactly how much.

11,369. What results have you got?—We got, in the first place, very considerable quantities of albumenoid ammonia throughout the area, which we particularly examined; that is to say, from Woolwich to Greenhithe, and we found considerable quantities—very considerable quantities, I may say—at all times of the tide; in fact, the mean results of our determinations in this way do not indicate any material difference between the composition of the water at different times of the tide except at high water, when there is distinctly less.

11,370. (*Chairman.*) For about how long before and after high water?—At various times; we have taken determinations at high water, low water, flood, and ebb; some exactly at high water and some exactly at low water; some taken at the flood, and some at various times in the ebb. I think we examined about 40 samples in that way.

11,371. (*Sir John Coode.*) You said you found the greatest difference at high water?—We found, as we expected, the least proportion at high water.

11,372. (*Chairman.*) But how much upon either side of the top of the tide?—The quantities found varied very much indeed, and I suppose that was due to a very great extent to our using unfiltered water; we found very great differences throughout the experiment.

11,373. (*Sir John Coode.*) But you would hardly use anything but unfiltered water, otherwise what would be the value of the experiment?—We thought it better to use unfiltered water, but other chemists we believe prefer to use filtered water.

11,374. (*Prof. Williamson.*) You use solely the permangate process for the determination of the albumenoid ammonia matter?—Yes; first distilling with sodium carbonate until the liquid was quite free from ammonia.

11,375. (*Mr. Lumley Smith.*) Upon the table you have handed in, Nos. 41 and 42 have been accidentally filtered?—Yes.

11,376. And therefore they are excluded from the average?—Yes; may we add that we excluded two other samples, one because the water was taken so near the outfall that it was more like sewage than water, and another, which contained a very large quantity of albumenoid ammonia, because it was taken in the wake of a very large steamer which stirred up the mud.

11,377. (*Sir John Coode.*) Where were the samples taken that were taken near the outfalls?—They were taken just off the outfalls.

11,378. That expression is rather vague?—Then I will say in the middle of the river just about opposite the outfall; but you will find that the variations in quantity are very great. I do not desire to overstate the evidence in any way, but we say we find very large quantities of albumenoid ammonia.

11,379. (*Mr. Lumley Smith.*) Will you read the averages?—I have taken them in parts per 100,000: high water, ·0645; low water, ·1050; at flood, ·1041, and at ebb, ·1012; those are taken after the exclusions which I have mentioned, which, for the reasons I have stated, it seemed unfair to include. The average of those numbers, including high water, is ·0937.

11,380. Can you compare that with observations made elsewhere, and will you give them?—Yes; there are very few; but we think it will hardly be denied that they represent the probabilities of the case.

11,381. (*Sir John Coode.*) By ·0937 you mean practically one millionth?—Yes; then we collected two samples in Sea Reach, one exactly at high water and the other at low water; the high water sample gave us ·0102 on the unfiltered water, and the low water sample gave us ·0154. We therefore succeeded in extracting from the water in our district about seven times the quantity of albumenoid ammonia that we could get from Sea Reach; that is what it comes to; but then we do not pin ourselves to those figures exactly. We made also another analysis of water at Charing Cross about the same time, which gave us at low water ·0233.

11,382. (*Mr. Lumley Smith.*) I understand you to say that you do not profess to get the quantity of putrescible nitrogenous matter by this process?—No.

11,383. What is the name of the process that you follow to get that?—We have not used any method; in fact, I believe there is no method of determining the quantity of organic matter of a putrescible kind present in water.

11,384. But what method did you follow for the albumenoid ammonia?—What is known as Wanklyn's process.

11,385. What you get is certainly less than what is in the water?—Certainly.

11,386. Will you just explain how that is—to what extent is that so?—When you distil nitrogenous matter with alkaline permanganate, you get a certain quantity of ammonia, as is universally agreed, by the destruction of this matter, the nitrogen is partly converted into ammonia, but we do not get the whole of the nitrogen in the form of ammonia, and there is no formula by which we know exactly how to multiply one to get the other; that is to say, we do not know what to multiply the albumenoid ammonia by in order to get at the quantity of organic matter.

11,387. Is it a matter of hypothesis as to the quantity of ammonia that you would get from any given quantity of nitrogenous matter?—Yes, there is no certain guide; I think that is universally known.

11,388. What have you taken?—We have made a kind of illustration which may, perhaps, illustrate the argument, and which I put in for what it is worth, and not with any attempt at definition. The quantities that we got were considerable, and if they were derived from a substance of the nature of albumen, it being supposed that these matters were obtained at first from albumenoid bodies, and if Mr. Wanklyn's original estimate were correct that you get two-thirds of the albumen in the form of ammonia—then I say (but it is a mere supposition obviously) that would give you ·7 parts by weight of nitrogenous organic matter, estimated as equal to albumen, per 100,000 of water. Now I say the experiments of most chemists would lead them to believe, as we believe, that the actual quantity of matter would be greater, and not less than that. I admit that it is a question of opinion, and I put the thing as an illustration, leaving it to the Commission to judge of its value; I found nothing upon it as fact.

11,389. Upon that assumption, what would be the weight in 100,000 parts of the average quantity of nitrogenous matter?—That would give about ·7 parts in 100,000, and I think it would have been greater, because I do not think you get so large a proportion of nitrogen as two-thirds in the form of albumenoid ammonia.

11,390. Is that all you have to tell us about the albumenoid ammonia?—Yes.

11,391. Now we pass to the nitrogen present as nitrates and nitrites; have you determined that in a number of cases?—In a few cases, not very many.

11,392. Does that appear upon tables you propose to hand in?—No; the determinations we have made ——.

11,393. Will you just tell us shortly what they amount to?—I can give you a series which appear to us to have a great value. In Sea Reach at high water ·1502 parts in 100,000 is nitrogen, as nitrates and nitrites both together, and at low water ·0760. Then, on another day, at Erith we got ·1190.

11,394. At what time of the tide?—At high water. Then there was one other experiment made, samples being taken at high water, at two hours ebb and at five hours ebb upon the same spot.

11,395. And I think you have a second series at Erith, have you not?—Yes; this which I am now giving is the first of these series. I have three determinations, which were made upon the same day upon the same spot at high water, two hours ebb and five hours ebb, and I am anxious to state these quantities, although I am quite aware that such a small number of analysis cannot have more than a certain value. The quantities were, at high water ·0975; at two hours ebb ·0580; at five hours ebb ·0270, showing a reduction in the quantity of the nitrates, which, as the Commission well know, is a matter of some importance. At Charing Cross, in the sample we collected, the nitrates were determined, and the quantity was ·2436 at low water, which is very much greater. Now, there is one remark that I should like to make with regard to these three experiments last quoted, that they seem to me to illustrate the reduction of nitrates by organic matter, which has been very fully and ably treated by Dr. Angus Smith in his last report on the Rivers Pollution Commission. Dr. Angus Smith has recently published a work upon the reduction of nitrates by excessive sewage matter, showing that the nitrogen is given off ultimately as nitrogen gas; that is in the report of the Local Government Board.

11,396. With regard to this reduction of the nitrates and nitrites, what conclusion do you draw; is that a reduction which might be due to the effect of sewage?—I think so.

11,397. Then the sewage has the effect of reducing the nitrates?—An excess of sewage has that effect. I must explain that I should not have asserted that upon these few experiments alone, but the very elaborate experiments of Dr. Angus Smith seem to be illustrated by these figures.

11,398. Now, we come to the oxidised nitrogen; what quantity did you find at Sea Reach at high-water?—We found ·1502 at high-water.

11,399. What is the next matter of importance that you come to?—The next matter is the dissolved oxygen; we made some experiments upon that.

11,400. This requires a little detail. First of all, what method did you adopt?—The Schützenberger process.

11,401. (*Prof. Williamson.*) How did you collect the water in which the dissolved oxygen was to be determined?—We found from some experiments which we made that the water absorbed oxygen very rapidly indeed, so rapidly that if we stoppered a bottle in the boat and took it to the club house and then tested it, we got more oxygen than if we made the same analysis in the boat.

11,402. (*Sir John Coode.*) Have you actually made an analysis in the boat?—Exactly; they were all made in the dingey; we rowed out in a dingey, and took a three-litre bottle, and immersed it a foot deep in the water, filled it at that depth, and took as much pains as possible by moving the bottle about to change the water several times, so as, as far as possible, to get the water of a fair sample, free from the air.

11,403. You mean you endeavoured to drive out from the bottle the water which first went in?—Yes.

11,404. So as to change the water?—Yes; we placed the bottle under the water, and moved it round and round, and we did all we possibly could to change the water underneath the surface. Then we raised the bottle up to the surface of the water, and one of us was ready with the burette with a cork at the top with the solution, and another poured a thick layer of paraffin oil upon the top, and then we syphoned it down to one litre, so as to get the minimum of exposure.

11,405. Are you quite sure that you did not get an undue proportion of the matter in suspension by that test?—I do not think it affected the oxygen test, which was the purpose of the experiment; we thought we should get in this way a fairer measure of the dissolved oxygen by doing it upon the spot than by taking it to the club house; if we carried it to the club house however carefully, even covered with petroleum, it gave a larger amount of oxygen; it absorbed oxygen during the journey.

11,406. (*Mr. Lumley Smith.*) Would you finish describing your process?—After that we applied the usual Schützenberger method, which is well known.

11,407. Do you consider it of importance to describe this method, or not?—No, I do not. I think the chemists among the Commissioners pretty well understand the details, I was then going to illustrate the method as to the absorption of oxygen. I can in some private notes, put in the experiments, if the Commission think it worth while. Upon a certain day we took some water, and determined it in the boat by the method I have described, and found ·1 cubic inch per gallon. We then repeated our collection precisely in the same way, but we carried the bottle to the club house, which was near, and did the analysis half an hour after the collection, and we got ·14, though there was a stoppered bottle and a thick layer of paraffin at the top. Then we let it stand four days, and repeated the experiment, and then we got ·38, which is nearly as high, I think, as in the quantities found by Dr. Tidy; and that, although the bottle was stoppered and covered with petroleum. There must have been a diffusion of oxygen, I presume.

11,408. (*Mr. Michael.*) Do you mean in the same sample?—In a sample taken at the same time and treated in the same way.

11,409. (*Sir John Coode.*) Did that happen more than once?—Yes, in every case. We always found that if we kept the samples a short time the quantity of oxygen rose, and we always found that we got the lowest indications by taking them in the boat upon the spot.

11,410. (*Mr. Michael.*) The four days retention gave you ·38?—Yes, the greatest quantity of oxygen.

11,411. And the simultaneous one ·1 and ·14?—Yes; the latter was after it went into the club house.

11,412. (*Mr. Lumley Smith.*) At what time of the year were your experiments made?—It was in cold wet weather in October.

11,413. Was that a kind of weather that was favourable to the water?—Decidely, because the solubility of the oxygen is greater in rough weather, there is more agitation in the water, and I should say the probability of aeration is greater decidedly.

11,414. I think you have a few results which you propose to give us of the amount of oxygen found, how have you taken them?—I have them in parts by weight per 100,000 parts, and also in cubic inches per gallon.

11,415. (*Dr. Stevenson.*) We have had the proportion given in cubic inches, and I think we will keep to that plan?—I will give it in that way. The reason we used parts by weight was that we were anxious to compare the parts by weight with the weight of the matter to be oxidised.

11,416. (*Mr. Michael.*) Have you the comparative results at the same time?—I can give you parts by weight in one column, and in the next, cubic inches to the gallon, the nearest I could go would be to give the average.

*The table was handed in, and was as follows:—*

| — | Parts by Weight in 100,000. | Cubic inches in one gallon |
|---|---|---|
| Water saturated with oxygen from air at 15° C., and 760 mm. P. | 0·85 | 1·74 |
| Erith, Oct. 11, 1882, high water | 0·11 | 0·22 |
| „ „ 29, „ „ (unusually high tide, rough water). | 0·20 | 0·41 |
| „ „ 15, „ flood | 0·11 | 0·22 |
| „ „ „ „ „ (near causeway) | 0·06 | 0·12 |
| „ „ 21, „ „ (heavy rain) | 0·12 | 0·24 |
| „ „ 11, „ ebb | 0·11 | 0·22 |
| „ „ 25, „ „ | 0·05 | 0·10 |
| Average, excluding Oct. 29 | 0·09 | 0·18 |
| Charing Cross, Oct. 13, 1882, low water | 0·66 | 1·35 |

*Prof. C. W. Heaton, F.I.C., F.C.S.*

7 March 1883.

11,417. (*Mr. Lumley Smith.*) What result do you draw from that?—The quantity of oxygen was so very small as to be practically nil; as far as the oxygen in the water went, there was next to none. If you find that you get a tenth of a cubic inch in a gallon of water, that quantity is very little. What I say about the matter is that the impurities in the water keep the dissolved oxygen very low in spite of its rapid absorption from the air.

11,418. You find very little oxygen, and you attribute that to the impurity of the water?—Yes, because the experiment made at about the same time at Charing Cross, though not upon the same day, gave us a very fair quantity of oxygen. I saw yesterday from Dr. Tidy's result that our determination of oxygen at Charing Cross was almost the same as his, ours being 1·35 cubic inches.

11,419. I see that the sample you have there containing the lowest amount of oxygen is the one that gives ·05 of a part?—The ·05 is by weight, but that is almost an exact equivalent to ·1 of a cubic inch, it happens that the cubic inches to the gallon are almost exactly twice the parts by weight per 100,000; you get, for instance, ·11 by weight, and ·22 by volume.

11,420. Now you say that those samples were taken in October when the weather was cool?—Yes.

11,421. Have you any opinion as to what would be the amount of oxygen in the summer?—We have no experiments unfortunately. I wish we had, but it seems reasonable to suppose that the quantity we have in the summer will not be greater than the smallest quantity; my opinion is that we should find that that would be representative of the summer condition of the Thames at that place, at the various states of the tide there is no important difference.

11,422. Have you formed any opinion as to the amount of oxygen that is required for the respiration of fishes?—I have hardly formed an opinion upon that matter, but I would suggest that the quantity found by our experiments would be absolutely insufficient, it seems to me that this quantity of oxygen would make it impossible for fish to breathe.

Adjourned to Tuesday next, at half past 12 'clock.

# TWENTY-NINTH DAY.

## Tuesday, 13th March 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
PROFESSOR WILLIAMSON, F.R.S.

FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, Esq., F.R.S., *Secretary.*

(*Mr. Michael.*) The Erith local authority and ourselves have discussed as to the admission of certain documents. We have now the opportunity of going over those documents with the Erith local authority, and they are here signed by myself and Mr. Morice, and I propose that they should be put in.

(*Mr. Morice.*) I went through the documents with my learned friend Mr. Michael (*the same were handed in. See Appendix AJ*).

Professor CHARLES WM. HEATON called again.

13 March 1883.

11,423. (*Mr. Lumley Smith.*) I think you heard the evidence given by Dr. Tidy with regard to the amount of free oxygen?—Yes, I did.

11,424. Your figures are rather lower than Dr. Tidy's, are they not?—In Erith district our figures are rather lower; in other districts in the few experiments we made they agree very closely.

11,425. Could you give any reason which would explain the apparent difference?—The determinations that we made were made in a boat upon the spot, and in that way we avoided the small absorption of oxygen from the atmosphere which is apt to take place in the journey from the boat to another place.

11,426. In the journey from the boat the samples would acquire fresh oxygen from the air?—Yes; the difference is not a very considerable one, but I believe that would account for the little difference that there is.

11,427. Now with regard to the conclusion to be drawn from the amount of the albumenoid ammonia as to the quantity of oxygen in the water; you wish, I believe, to make an observation with regard to that for the purpose of illustrating your table?—The members of the Commission will remember that I said the results of our experiments had been to show that the quantity of albumenoid ammonia, that is, ammonia which is believed to be derived from putrescible animal matters, was considerable throughout the area examined, and that it did not appear to differ very much with the states of the tide. We found in flood tide quantities that were frequently as great as in the ebb tide when the sewage was coming down. The inference that we found upon that is that the quantity of oxygen in the water being kept constantly very low by the sewage, there is not time in the course of a single tide for the destruction of these nitrogenous matters, and also that these matters appear to undergo putrefaction before oxidation; they are, as a rule, putrefied first and oxidised afterwards.

11,428. (*Sir John Coode.*) I thought you said upon the last occasion that the oxidation was immediate?—Not with regard to these particular kinds of matters; such a substance as pure albumen, for instance.

11,429. You were speaking of the general body of sewage, and stated that it would absorb the oxygen?—Yes. Our experiments were only directed to get some evidence with regard to those bodies capable of putrefaction, not so much as to the bodies already putrefied. We wished to account for a smell which was found upon the river, and that smell appeared to us to come from putrefaction; so we used this method, thinking that that would give us the best evidence in regard to it. I should like to draw the attention of the Commissioners to Dr. Angus Smith's Report to which I have previously alluded. There are two or three passages in that report which seemed to confirm our conclusions in a very remarkable way. The report I am referring to is the report of Dr. Angus

Smith, the Chief Commissioner under the Rivers Pollution Act, pages 45 and 46 (*handing in the same*). Dr. Angus Smith made experiments upon the artificial aeration of sewage, that is to say, aerating it by forcing air through it to observe the effect of aeration, and he records those results, and they, are very interesting indeed. He makes this remark to begin with: "I must, however, add that in the following experi- "ments the amount of air supplied is greater than "that usually given to sewage water in nature." Then on the following page, page 46, he remarks: "The albumenoid ammonia is not much changed in "any of the aerated specimens." That is exactly what we found working in a different way upon the Thames, and then he says, "and this we might expect "from the absence of putrefaction." I only saw this a few days ago; he attributes the slow disappearance of the albumenoid ammonia in his experiments to the absence of putrefaction; the numbers are 10·6, 10·4, and 10·2.

11,430. (*Mr. Lumley Smith.*) Practically, with regard to your conclusion, as I understand, in warm weather putrefaction takes place tolerably fast?—Yes.

11,431. And during that time the sewage changes its character, does it not?—It does; it smells.

11,432. You have it accompanied by a great smell, and there is a disintegration and destruction of the sewage?—Yes.

11,433. But in cold weather is there putrefaction going on as fast as in hot weather, or does it go on at all?—It goes on much more slowly, so that there is a better chance for the oxygen to destroy it. When the putrefaction of a large quantity of matter is going on and the oxygen is being rapidly absorbed there is a smell, but when the putrefaction is very slow there would be no smell. You will have fæcal matter in the water unoxidized, but not smelling very much; it is only when putrefaction with insufficient oxidation takes place, in our opinion, that you have a smell.

11,434. (*Sir John Coode.*) Are the injurious effects of sewage, in your opinion, in proportion to the noxious smell?—That is more than I can say with safety.

11,435. There is no rule laid down upon that point?—Not amongst chemists certainly. I do not know whether physicians can answer the question in any way.

11,436. (*Chairman.*) With regard to the question whether sewage is injurious or not, can you answer any questions upon that point?—I cannot give any evidence upon that point.

(*Chairman.*) I mention it because I have heard, though I do not know what truth there is in it, that the men who go down the sewers are the healthiest men in London.

11,437. (*Mr. Lumley Smith.*) I asked you a question about the hot weather, but I did not ask you the corresponding question about the cold weather. In the cold weather does the sewage remain for some time in the water without changing its character?—It does.

11,438. Does that appear from your experiments with the albumeniod ammonia?—Yes.

11,439. In hot weather it changes character very rapidly, and is accompanied by a great smell; in cold weather it does not change its character so rapidly, but remains a longer time in the water?—Yes, and probably over a larger area.

11,440. You have some figures which you wish to give the Commission with regard to the quantity of oxygen in the water; will you mention them?—I gave a sort of suppositious case, that the albumenoid ammonia was derived from something analogous to albumen itself in order to get a number to work upon, and in that case I said the lowest quantity indicated by our figures would be ·7 of a part of nitrogenous organic matter in 100,000. On that assumption I calculated the weight of oxygen that would be required to destroy it; supposing the nitrogen were given off as gas and that the carbon were converted into carbonic acid gas, it would require 1¼ parts by weight of oxygen in 100,000 parts to destroy the albumenoids only; taking no account of other matter in the water which also requires oxygen. This I give as no more than an illustration of the very great quantity of oxygen that is required to destroy this organic matter, and when you compare that with the very small quantity of oxygen which we actually find, the matter seems to have a certain weight and value to me.

11,441. (*Dr. de Chaumont.*) Do you agree that the power of oxygen diminishes with the dilution, that is to say, with the smallness of the quantity of it?—I have no evidence to give to the Commission upon that point.

11,442. For instance, if the oxygen stands at 2 per 100,000 parts, its power is very much more in proportion than if it stood at 1½?—I know nothing upon that matter.

11,443. (*Dr. Stevenson.*) You gave some evidence to show that the amount of oxygen in the water at Erith was very low?—Yes.

11,444. And that it was very rapidly absorbed from the air?—Yes.

11,445. Would that tend to show that the oxidation was going on rapidly or slowly in the water?—It would show that the absorption of the oxygen by the water was rapid. I should consider that water nearly destitute of oxygen would absorb it more rapidly than if it were well aerated.

11,446. What inference would you draw from the rapid disappearance of the oxygen?—I should have thought the fact of itself no very convincing proof, but that the nitrogenous matter remained unchanged. I am not aware whether we have any experiments to show the rate at which oxygen is absorbed from the air, but whether it be slow or rapid, the nitrogenous matters do not get readily oxidized; that is all we can get.

11,447. (*Sir John Coode.*) If the absorption of oxygen is so extremely rapid in a bottle, would it not be equally rapid in the river?—There is no doubt it would.

11,448. The absorption of oxygen would not go on more rapidly in bottles than in the river?—No; undoubtedly the absorption of oxygen in the river must be very rapid.

11,449. If the quantity keeps very low and the absorption is so rapid as you say, what becomes of the oxygen which is absorbed?—That is absorbed by the sewage bodies. We find so much putrescible matter in a flood tide, that it is plain the oxygen does not destroy the whole or even any very large portion of it in the Thames.

11,450. Does it not come to this, that the oxygen in the water is not enough to oxidize the sewage?—Certain matters in the sewage are not eaten up; these nitrogenous matters, one would say, were tougher, and resisted the action of the oxygen.

11,451. (*Dr. de Chaumont.*) Is it not the fact that the nitrogenous matter putrifies more rapidly than non-nitrogenous matter?—Yes, but it does not oxidize to any extent until it is putrified. I think the cold arrests putrefaction, and so indirectly the oxidation, and also that there is a very large quantity of oxygen required; however rapid the absorption of oxygen from the air may be there is plenty for it to do.

11,452. (*Mr. Lumley Smith.*) Do you consider that you find oxygen enough at present in the water to oxidise the nitrogenous matter which is found there?—It would be a question of space I think.

11,453. Taking it where you have sampled the water and have ascertained the amount of oxygen, and have either ascertained or estimated the nitrogenous matter, do you find oxygen enough to oxidize what is there?—No; from Woolwich down to Greenhithe we find the water polluted at all times of the tide with nitrogenous organic matter, and we find very little oxygen.

11,454. Do you consider that there is oxygen enough there for the respiration of fishes?—That is more a physiological question than a chemical one; but I should like to draw the attention of the scientific members of this Commission to the very

*Prof. C. W. Heaton.*

13 March 1883.

small quantity of oxygen that we find present, and I will leave it to them to decide whether it is sufficient. I say as a chemist, however, that I should think the quantity of oxygen which I found in this district was insufficient for the breathing of fishes; but as it is a physiological point, I should prefer not to give a further opinion than that upon the question.

11,455. (*Dr. Stevenson.*) You have paid attention to the subject of physiological chemistry, I presume; you lecture at some schools, I believe?—I have done so, but not completely. I could not say what quantity of oxygen a fish would require for its respiration.

11,456. (*Mr. Lumley Smith.*) I believe you have taken some samples of mud, have you not, at Erith?—Yes.

11,457. And you kept them in your laboratory for some time?—Yes.

11,458. Could you tell us what happened to them; did they change their character?—Our examinations of the mud were unfortunately commenced very late in the year. We did not make very many observations, and I cannot say that I think they are very conclusive.

*The Chairman* intimated that the evidence of the witness appeared to be largely of a hypothetical character, whereas the question before the Commission was one of fact.

(*Witness.*) I can only of course venture to suggest an explanation of the facts observed.

11,459. (*Mr. Lumley Smith.*) Did you take some of this Erith mud into your laboratory?—Yes.

11,460. What happened to it when you kept it in the laboratory?—In a few days it smelt most offensively, and was full of large red worms.

11,461. Which you had not seen before?—Which I had not noticed before.

11,462. Not in the specimen which you took?—They were certainly not there when we took the specimen; they were observed in a few days.

11,463. (*Chairman.*) They must have been hatched, I presume?—There they were.

11,464. (*Dr. Stevenson.*) Do you think that those worms are characteristic of sewage?—I do not know that at all.

11,465. I suppose in a pond on Hampstead Heath at the top of a hill there is not much sewage?—I presume not.

11,466. Do you know that mud worms exist there?—I give no opinion upon that. I know only that the mud smelt badly, and that there were worms in it.

Cross-examined by Mr. Michael.

11,467. We have heard from some witnesses that the presence of sewage was determined because there were no worms in the mud. Do you mean to say that this mud contained sewage because there were worms in it?—No.

11,468. If I followed you rightly, you found a very small quantity of oxygen in the water?—In the water at Erith.

11,469. Will you state the mode in which you proceeded in making your determination?—I collected the water in a bottle, and in drawing it out of the river we covered it with a layer of paraffin oil as it came out, so that the bottle should be completely full; then we syphoned it off carefully down to one litre, and then immediately added from an alkalimeter which was standing ready in the boat the Schützenberger solution, and then having got the number of measures required to destroy the blue colour of the re-agent we drew off another litre from the same bottle, aerated it by violent and repeated shaking, and then repeated the determination, the whole thing being done in a very short time.

11,470. After keeping this water three or four days with a cover of paraffin oil, did I rightly apprehend you to say that there was three times the quantity of oxygen that there was previously to be found in the water?—Yes, just about that.

11,471. Where do you tell the Commission that the oxygen comes from?—I have no doubt it came from the air.

11,472. In spite of being covered with the paraffin oil?—Yes.

11,473. Now I will ask you this: if it is so impossible to prevent oxygen from getting to the water in a bottle under those circumstances, must not the water in the river itself, exposed as it is to the air, much more rapidly absorb oxygen?—Yes, undoubtedly.

11,474. Is it not the fact that the sewage is being constantly subjected to fresh accesses of oxygen brought into it from the air, the effect of which is to decompose it?—Undoubtedly.

11,475. Therefore, your finding at that particular moment only a certain quantity of oxygen, and in four days three times the quantity, shows, first, that a certain amount has been taken away to decompose the sewage, and, secondly, that fresh accesses of oxygen are continually coming into the water?—Certainly. Upon the last occasion I gave evidence as to the reduction of the nitrates in the water by sewage; now the fact that the nitrates are reduced is in itself, I hold, a strong evidence of the insufficiency of the oxygen; the sewage draws upon the nitrates, not only upon the dissolved oxygen of the water.

11,476. Now a word more with respect to Dr. Angus Smith and his report. I will not trouble the Commission by reading it. Is it not the fact that he makes these two propositions: first, that sewage running in water under ordinary circumstances, and not in sewers, is not deleterious to the public health?—I cannot answer that question.

11,477. But you quoted Dr. Angus Smith's Report. Is not that one of the conclusions at which he arrives?—Possibly; but honestly I have not read it. I found this report only a few days ago, and the passages I have quoted struck me as a valuable illustration of the evidence I had to bring forward.

11,478. I will quote one passage from the report.

*Mr. Lumley Smith* objected to the question.

*The Chairman* stated that the question might be put.

11,479. (*Mr. Michael.*) I will refer you to page 34 of the report, where Dr. Angus Smith is justifying his former report; he says, "This raises a question to be solved, but the fact is certain that fevers have not been traced to the escape of gases of putrefaction when there has been a large amount of water and exposure to the air. But they have been found when the water is not very great in amount, and the decomposition is made under cover as in sewers." Is not that from your experience the real distinction between sewage in sewers and sewage exposed to the air in running water?—I cannot say yes or no to that question. The fact is, I should not like to answer the question without studying the passage, and carefully considering it. I am not a medical man. I know nothing of its influence upon health.

11,479*a*. You know nothing of the application of this matter to health, or of physiological chemistry?—No, not as enabling me to answer your question.

11,480. Now a word or two further with respect to your analyses. Am I right in saying that nearly all of them were conducted upon water containing suspended matter?—Undoubtedly.

11,481. In some cases, if I rightly apprehended you, you took the water when the bottom was stirred up, as in the wake of a steamer?—That happened in one case; but if you turn to the table, I think you will find that that is excluded. We thought that in two samples the albumenoid ammonia was very high indeed, and we struck them both out because we thought the conditions of the river at the moment were unfair.

11,482. Am I right in saying that the river varies

in suspended matter in proportion to the depth, and that unless you had a very large number of analyses you could not draw a fair average?—I should be very sorry to make anything much of that average. I have been most careful not to overstate our case to the Commission. In that particular we found large quantities, but very variable quantities.

11,483. What is the result which you would wish the Commission to understand as to the difference between free ammonia and albumenoid ammonia? Where you find a small quantity of saline ammonia and a large quantity of albumenoid ammonia, what is the conclusion you would draw?—I should draw no conclusion from it in the conditions of our experiment with suspended matter in water.

11,484. Therefore, you have no means of guiding the Commission as to anything that is to be drawn from the great mass of your experiments?—I think, as regards the free ammonia, very little will be deduced from them, except that there is general sewage pollution; but that, I presume, will not be doubted.

11,485. Then the quantity of saline ammonia, if I rightly understand what you say, would furnish no indication as to pollution?—I would not say that; I would only say that for the purpose of the argument that I wish to bring out, the free ammonia does not bring out results which are useful to me.

11,486. Now you have made two analyses of filtered water?—Yes, I have.

11,487. Is it not the fact that with regard to those analyses the quantity of matter found was very nearly the same at Kingston as at the Corinthian Yacht Club at Erith, the point you have taken as showing pollution?—If you are referring to samples 41 and 42 there is not much difference.

11,488. Therefore, as far as we are to be governed by those two analyses, the point you have selected, namely, at the Corinthian Yacht Club, shows the same amount of impurity by the albumenoid ammonia test as you find at Kingston?—But you must not overlook the fact that those were filtered samples, whilst the Kingston water was unfiltered.

11,489. But the Kingston water is in a state fit to be drunk, is it not?—I do not know that.

11,490. Was there any suspended matter in the filtered water?—That I cannot say; but that sample was struck out of our table, and was struck out because we had nobody here to give evidence as to who took it or how it was taken.

11,491. Had you any means of determining the quantity of suspended matter at varying depths in the river?—No.

11,492. Would your analyses make any discrimination between the organic matter alive and dead?—No.

11,493. If there were a great number of microscopic animals or microscopic vegetables, algæ or confervoids, you would have had the same means by analysis as you would by chemistry of ascertaining the amount of albumenoid ammonia?—I think not.

11,494. Will you explain why not?—Because we know, as a matter of fact, that certain sewage matters which are thrown into the river—the common sewage of the river—does yield a large quantity of albumenoid ammonia. I quite admit the weaknesses of the method in many particulars. All these things are well known to every chemist; but it is generally agreed amongst chemists, I think, that the albumenoid ammonia in a sewage polluted river does come from the sewage.

11,495. With regard to dead animal and vegetable matter, is that composed of any gases different from the gases which make up sewage matter?—No.

11,496. Therefore, as far as chemistry is concerned, can you discriminate between organic, animal, and vegetable matter which is dead in the water, and animal and vegetable matter which has come out of the sewage?—I think we can in this way: the sea-water contains much animal nitrogenous matter living and dead; the sample we took at night was when the water was covered with phosphorescence. Now that water, although it contains much nitrogen, does not yield albumenoid ammonia. I think the albumenoid ammonia is perhaps the best test we have in a water of this kind for sewage matter.

11,497. (*Sir P. Benson Maxwell.*) Laying aside the fact which seems to you to import that this is a water polluted with sewage, if you were given a sample of water, and were not told where it was drawn from, and you found there was albumenoid ammonia in it, would the inference be irresistible that it must come from the sewage; might it not also come from these confervoid and other organic substances, such as were suggested by Mr. Michael?—If I knew nothing of the history of the water I should draw a much more guarded inference than I should from the Thames, where I know that sewage is thrown in.

11,498. When you find albumenoid ammonia in the Thames, you say, "I know that comes from some "organic substance, and as I know the sewage is "thrown into the river I infer that it comes from the "sewage"?—Yes.

11,499. Supposing that you were supplied with a sample taken from a river in America, and you found this albumenoid ammonia in it, you would not necessarily come to the conclusion that the river was polluted with sewage, would you?—I could not go further than saying that it was polluted by nitrogenous organic matter.

11,500. (*Mr. Michael.*) All you say is, "I find a "certain quantity of nitrogenous organic matter "which I assume comes from sewage"?—I think you rather understate my case.

11,501. (*Chairman.*) It seems to me that you answered the point when you answered Sir Benson Maxwell's question. You say that all you know is that it proceeds from some nitrogenous matter, but whether it was sewage, or fæcal, or some other organic matter, you could not tell?—Yes. I leave the inference to be founded upon that, that the sewage is the cause of the very large quantity of albumenoid ammonia that we find there.

11,502. (*Dr. de Chaumont.*) Is it not the fact that no chemist founds his observations upon the presence of one particular ingredient; you would take into account the free ammonia and the amount of chlorine, and also you would desire to have the history of the water before you could arrive at the source of pollution?—Yes, quite so.

11,503. (*Mr. Michael.*) Therefore, chemical analysis does not enable you to say that there is so much pollution in the river?—No.

11,504. As far as your analyses have gone, may they not be taken to be merely analyses of the suspended matter in the water?—Not only that, but analyses of the matter both dissolved and suspended in the water when the sample was taken.

11,505. By the combustion process does not the same impossibility apply in discriminating between sewage matter and animal matter?—I think there is no impossibility in the matter we are dealing with; it seems to me certain that the albumenoid ammonia found in our experiments comes from nitrogenous organic matter capable of putrefaction.

11,506. So would the million animalculæ in 10 drops of water?—No, pardon me, they do not give so much life as the sea-water.

11,507. Assume sewage poured out into oxygenated water fed upon by animalculæ, and 10 drops of that water containing a million of those animals dead abstracted from the water, and you as a chemist analysing those 10 drops of water, could you tell whether the carbon or the nitrogen, or the results obtained by the albumenoid ammonia test, were really due to sewage, or to the decaying bodies of those animals?—I could not say with certainty.

(*Sir John Coode.*) I think I understand the witness to say that he does not put it so high as absolute proof, but that it is a very strong inference.

(*Witness.*) Yes, that is what I mean.

11,508–9. (*Chairman.*) As I understand, a sufficient number of dead dogs would produce that effect?—Yes.

*Prof. C. W. Heaton.*

13 March 1883.

11,510. But there not being that sufficient number of dead dogs there, but you knowing sewage to be there have attributed that to the sewage?—Yes, that is so.

11,511. (*Mr. Michael.*) Now, passing from that, I think you have resided, have you not, at Erith for some time?—Yes.

11,512. What do you say with respect to the noxious trades which are conducted on both sides of the river there?—Those noxious trades are very disagreeable.

11,513. Have you had to complain constantly on the vapours which issue from those manufactories of both sides of the river?—Undoubtedly. I am very familiar with them all. I gave evidence before the Royal Commission with regard to them.

11,514. Do they exist at the present time?—They do.

The witness withdrew.

Professor Richard V. Tuson, F.I.C., Professor of Chemistry in the Royal Veterinary College; Associate of the Society of Medical Officers of Health, examined.

*Prof. R. V. Tuson, F.I.C.*

11,515. (*Mr. Balfour Browne.*) You made all the experiments which have been spoken to by Professor Heaton?—Quite so.

11,516. You were with him, were you not?—Yes.

11,517. And as far as scientific matters are concerned you have nothing to add to his evidence?—I have nothing to add.

11,518. (*Chairman.*) Do you concur in what has been said by him in answer to questions put by Mr. Michael in cross-examination?—Quite so.

11,519. (*Mr. Balfour Browne.*) Have you been acquainted with the river for a much longer period than Professor Heaton has?—I believe so, for the last 22 or 23 years.

11,520. How is that; have you been a yachtsman?—I have been yachting all the time constantly upon the river.

11,521. I think for a considerable number of years you have been resident at Erith?—I have been resident at Erith for 11 years.

11,522. And have you been during those 11 years frequently upon the river?—Yes, at all times of the day, and frequently at night.

11,523. And you have constantly been at the yacht club which is upon the side of the river?—Yes.

11,524. Are you able, apart from chemical analyses, to judge of the river from the condition of the river itself?—I consider myself fully qualified from personal knowledge to judge of the general condition and appearance of the river.

11,525. Is it getting better or worse, speaking from what you know of the condition of the river?—I should say it is steadily getting worse and worse from year to year.

11,526. (*Chairman.*) Would you give the Commission the boundaries between which it is getting worse?—I would take it, say, from Woolwich Piér as far as Greenhithe.

11,527. (*Mr. Balfour Browne.*) Is it true that for the last 10 years the river has been getting worse?—Undoubtedly, judging from the appearance of the river, the blackness of the river, and the stench arising from it, and its turbidity.

11,528. In all those respects you say it is getting worse?—Yes.

11,529. And within the limits which you have mentioned to my Lord Bramwell?—Yes.

11,530. Do you know the middle of Long Reach?—Yes.

11,531. Is the river in that condition so far down as Long Reach?—Yes.

11,532. Is it turbid, black, and sewage like?—Yes, turbid, black, and sewage like, with innumerable bubbles slowly or sluggishly rising and discharging gas, and in hot weather this is accompanied by a most fearful stench.

11,533. (*Sir John Coode.*) Do you see that gas rising at this period of the year?—No; for the reason that I am not so frequently upon the river at this period of the year.

11,534. (*Mr. Balfour Browne.*) Can you tell the Commission whether the bottoms of boats and yachts have to be scraped more frequently than was formerly required there?—Yes.

11,535. (*Sir P. Benson Maxwell.*) I suppose you mean that a quantity of stuff collects upon the bottoms of the boats?—Yes.

11,536. What kind of stuff is it?—A blackish kind of mud, followed very often by a vegetable growth; and when it is scraped off the stench from it is very bad.

11,537. What kind of smell is it?—It is like the smell of fæcal matter decomposing.

11,538. (*Mr. Balfour Browne.*) Have you any knowledge of bathing at Erith?—When I first went to live there, 11 years ago next June, bathing from the dummy at the end of the pier used to take place nearly every day, whereas I never now see any bathing taking place there except by mud-larks, such as you would see bathing off a place like this; but the gentlemen of the place never bathe there now.

11,539. You know the Corinthian Club; do you know whether the stench there is much worse than it used to be?—Yes, at low water in hot weather the stench is exceedingly bad.

11,540. Does this evidence which you have been giving to the Commission bear out the results of the scientific examinations which you made with Professor Heaton?—Yes, I think so.

Cross-examined by Mr. Michael.

11,541. Did I understand you to wish the Commission to regard what you said with reference to gas as being an inevitable test of sewage in water; if sewage is poured into a running stream is there a large quantity of gas given off in it?—Yes, I look upon that abundant and general evolution of gas accompanied by a bad smell and accompanied by black turbidity in the water as evidence of sewage, because I have seen immense volumes of sewage matter vomited forth from the northern outfall having exactly the same appearance.

11,542. But is the presence of gas in water to be taken as indisputable evidence of the existence of sewage in the water?—I should say that fœtid gas was.

11,543. Did you ever analyse what the mud was?—Never; I simply smelt it.

11,544. Now, with regard to the mud at Erith, has that in your opinion increased or decreased in quantity?—My opinion of it is that it has increased especially by the causeway.

11,545. Are you aware where the outfalls of the sewage at Erith are?—I know one small pipe coming down just below Erith Pier.

11,546. Is that the place where the bathing used to take place?—No, it is above it, and at high water.

11,547. What do you say with respect to the noxious smells which are given off by the manufactories upon the banks of the river?—I say that as the result of many years experience I am able to distinguish five distinct bad smells, four of them arising from chemical works upon the banks of the river, and one of them from the river itself.

11,548. Are they particularly disagreeable and noxious in your opinion?—As to their being noxious I can offer no opinion; but as to their being obnoxious or offensive, I am very strongly of opinion that they are.

*Prof. R. V. Tuson, F.I.C.*

13 March 1883.

11,549. (*Chairman.*) Do you mean that you can distinguish them all at the same time?—I will not go so far as that; but I am living, as the crow flies, about three-quarters of a mile from the river, and when the wind sets in a certain direction towards my house I can smell Calenders'. I can smell another place which is known there as Rose Cottage, where they make scutch and glue, and things of that sort. Then there is another work which I can distinguish.

11,550. (*Sir John Coode.*) Which predominates, you mean?—Yes.

11,551. (*Mr. Michael.*) Is not it the fact that at the Corinthian Club House there is an eddy of the river, that the river does not run as it does upon the other side, but that there is an eddy which comes right back?—Yes.

11,552. So that whatever is in the stream is brought back to this particular spot?—Yes.

11,553. (*Sir John Coode.*) You said that the river was getting steadily worse year by year. Would you say it was worse last year than in the summer previously?—No, I would not say that, because the weather was cold last year.

11,554. What you mean is, that there is a steady growth for the worse, setting aside exceptional seasons?—Yes.

11,555. (*Dr. Stevenson.*) With regard to the table that Professor Heaton put in, showing the parts of oxygen absorbed, does that mean absorbed by the permanganate test?—Yes.

*Mr. Balfour Browne* stated that he had no questions to ask the witness in re-examination.

Dr. Charles Meymott Tidy recalled and further examined.

*Dr. C. M. Tidy.*

11,556. (*Mr. Balfour Browne.*) I think you wish to explain a little further your experiments on the oxidation of sewage?—Yes. I beg to hand in a photograph of the apparatus used by me in my oxidation experiments. Dr. Frankland raised some question about this apparatus; this apparatus was a series of troughs put up in the garden of a house which I specially took, for the experiment, in the north of London. The series of experiments which were made upon the oxidation in running water occupied about five months with this apparatus, and in all 118 experiments were made with it. Dr. Frankland, in answer to these experiments, referred to the circumstances that I had said in my paper that, in the first instance, all my results showed absolutely against my views of oxidation. I should like to say that the conclusion of the sentence was that "the reasons were manifest." The reasons why my results did show against oxidation were these:—First, that "blacks" would keep getting into the water from the chimneys, which increased the organic carbon very largely; and, secondly, that at first the troughs were simply made of wood, to which various matters would be apt to adhere. In order to meet that objection I had to adopt a very large number of contrivances; the first was the lining of the trough with glass, which was cemented to the wood, and which was distinctly noticed as being cemented to the wood; that was in order to prevent the blacks and other matters being caught in the wood; the second was that the outside was covered with cotton-wool in a most elaborate method to allow the free access of air, but to prevent the increase of organic carbon from the blacks. After I had completed this work I never failed once in proving a decrease of organic carbon. The sewage was filtered and mixed with New River water, and every trough was washed out at the termination of every experiment; it was pumped. You will see the pump at one side; there was a little cistern at the top and a little cistern at the bottom in order that it should go through the trough again. Then I answered a question about bacteria on the last occasion. I have no record of any bacteria being noted, but I cannot say but what bacteria were formed, but if they were they would occur in the river just as they would in these troughs; and if they assisted oxidation they would assist it in the river just as they would in these troughs. I trust the Commission will excuse my mentioning these experiments of mine, but they cost a great deal of labour, and to my mind those experiments have never been answered. Then there was another thing referred to as one of my arguments in favour of oxidation, that I had spoken of having seen the River Irwell loaded with black matter; and Dr. Frankland, I think, quoted me as having said that when it passed through Warrington it was perfectly clear, whereupon, Dr. Frankland said that the River Irwell did not pass through Warrington. I did not say it did. What I said in my pamphlet was perfectly distinct upon that point, and I think it is necessary that I should just put it right. I did not call it the River Irwell, because I was perfectly aware that the Mersey joined it. I called it "the stream"; I did not call it the Irwell at all. What I stated was, "I have seen the River Irwell at "Manchester polluted with every form of filth, per-"sonal and manufacturing; at Warrington, after a "flow of 9 miles, the offensive character of the stream "had entirely disappeared." Then I give the figures to show that, as a matter of fact, the Irwell was a little better than the Mersey.

11,557. (*Sir John Coode.*) During the experiments the apparatus was entirely encased in the cotton wool?—Entirely; indeed I think the amount of care taken in carrying out these experiments can hardly be imagined.

The witness withdrew.

Mr. Lionel S. Beale, M.B., F.R.S., examined.

*Mr. L. S. Beale, M.B., F.R.S.*

11,558. (*Mr. Lumley Smith.*) My Lord, this evidence is to show how far any information can be got from the microscope. (*To the witness.*) I believe you are a Fellow of the Royal Society?—I am.

11,559. (*Chairman.*) And of the Royal Microscopical Society?—Yes.

11,560. (*Mr. Lumley Smith.*) Now, I believe you received, did you not, from Dr. Collingridge, various samples of mud from different banks between Gravesend and Chelsea?—I received 25 of them.

11,561. And you received them for the purpose, did you not, of investigating them with the miscroscope?—I did.

11,562. Have you examined them, and are you able to tell us to what extent they show signs of sewage?—Principally from the presence of matter which looks like fæcal matter, and from the presence of many substances which have passed through the alimentary canal.

11,563. Will you allow me to interrupt you, you have examined them for that purpose, have you not?—Yes for that purpose.

11,564. I think it would be convenient, before you state what you found, to ask you to say one word upon the method you adopted. If a portion of the mud is placed upon a glass slide immediately, are you able to examine it with facility?—You cannot do so, because the particles of sand are so large as to prevent you from getting a sufficiently thin layer to see the more important structures.

11,565. Then there is a practical difficulty in getting a sufficiently thin layer of mud if you place the mud immediately upon the slide?—Yes, there is a practical difficulty.

11,566. I believe you then tried, did you not, putting it into the water and stirring it up and letting it settle?—In this way you can get the light particles, but you can form under those circumstances no idea of the proportion which the organic materials bear to the sand.

*Mr. L. S. Beale, M.B., F.R.S.*

13 March 1883.

11,567. Then that did not answer?—That did not do.

11,568. Then will you tell the Commission what was the mode that you found satisfactory?—I took a small piece of the mud, perhaps the size of a pea, and mixed it with an equal quantity of glycerine, and then, when the mixture was complete, I examined small portions from different parts of the mass under thin glass, taking care to separate the coarser particles of sand, so as to get a sufficiently thin layer.

11,569. Is that mode, in your judgment, satisfactory?—Yes, fairly satisfactory.

11,570. Has it any advantage with regard to the length of time that the mud will keep without undergoing change?—By this process one is enabled to keep specimens of different muds for almost any length of time, examine them at leisure, and compare one with the other. No change takes place; they may be kept for months, and I believe for many years, 15 or 20 years, without change.

11,571. Were you able by those means to see almost all the constituents of the mud?—I think so. I paid more attention to the organic than to the inorganic constituents. I paid little attention to the particular kind of sand.

11,572. Now with regard to what you do find under the microscope; first of all, does the microscope give you any information or not as to the quantity of each constituent that there is in the mud?—I am afraid only roughly.

11,573. Of course when you look through your microscope you see something which may have come from sewage, but in what way can you get roughly at the absolute quantities?—By noticing the number of particles in one field, and then shifting the specimen onwards a certain distance, and noticing whether, say in 20 fields, you meet with one, two, or more specimens of the same substance or kind of thing.

11,574. If in 20 fields you only find one specimen of one thing while in 20 other fields you find 20 specimens of another, you assume that there are 20 times as much of the one thing as of the other?—Quite so.

11,575. Have you identified in the mud any substances which had formed part of human excrement?—Yes, human excrement itself. I also found portions of muscle, of vegetable fibre, and starch granules.

11,576. Did you find any other?—I found yellow elastic tissue and various forms of vegetable tissue. The first is very striking, it is very indigestible, and is not dissolved by the juices of the intestines of the stomach.

11,577. (*Dr. Stevenson.*) Would you tell the Commission what yellow elastic tissue indicates?—One form of yellow elastic tissue comes from the ligament of the neck, pieces of it are taken off in a mutton chop, another form comes from the larger arteries of the body. It is hardly possible to eat a mutton chop without taking portions of the yellow elastic tissue from the ligament of the neck, which keeps the head of the animal raised. Not only so, but you can distinguish, I think, with tolerable certainty, the difference between the yellow elastic tissue from the artery and that from the ligament of the neck.

11,578. (*Mr. Lumley Smith.*) First of all, I will ask you generally; these matters are constituents of human food, are they not?—Undoubtedly.

11,579. Now, notwithstanding their having passed through the alimentary canal and through the sewer and been in the Thames, do you in fact find those elements in the mud?—Yes.

11,580. Have they well-marked characters which make them recognisable?—They have a very well-marked character; there is no doubt about them at all in many cases.

11,581. Now a word or two about each; first of all, with regard to the vegetable tissue; what has that proceeded from?—Many different forms of vegetable tissue are found, but notably common cabbage.

11,582. Common cabbage might, of course, have fallen into the river, or it might have got there in the way which is suggested by you; is there anything to distinguish between whether it has come to an untimely fate and been drowned, or whether it has passed through the alimentary canal?—In many of the muds near Crossness one finds a vast number of these spiral fibres in exactly the same state as those which may be obtained from the fæces of a person who has had a meal of cabbage some time before.

11,583. The spirals are a portion of the vegetable tissue?—Yes, the spiral is the least soluble portion.

11,584. Is there anything in the colour which shows that the spirals have passed through the alimentary canal?—Not in the spirals, but in the tissue close to the spiral; this gets stained with the yellow matter which is so characteristic of fæces.

(*The witness handed in drawings illustrative of his evidence.*)

11,585. You say that you find these spirals in large numbers in the mud from near the Crossness outfalls?—Yes.

11,586. Do you find them in the other muds that you have examined?—In a good many. Of spiral fibres from vegetable tissue in the mud from Crossness, two specimens were found, taken from different places; in the mud from Barking bank; in the mud from Erith; three specimens in the mud from Beckton; in the mud from 40 feet below Barking outfall; in the mud from the bank at the upper end of the jetty at Crossness; off the centre at Barking outfall; at the sewer by the steps just above Woolwich Pier; in mud taken at East Greenwich; in mud taken at Blackwall, and in mud taken at Chelsea.

11,587. And you find vegetable tissues in a form and condition which, in your judgment, shows that they passed through the alimentary canal?—Yes.

11,588. Have you angthing more to say with regard to the vegetable tissue?—With regard to the spiral fibre, I ought to say that there are different forms of vegetable spiral fibre.

11,589. Do they resist the gastric juice?—Very much so, and they resist decomposition.

11,590. The rest of the fibre dissolves away from it and leaves the spiral, does not it, so that you get the spiral separate?—Yes, and you get portions of the spiral vessel and also some spiral vessels from tea-leaves and cells from tea-leaves.

11,591. Do you find those at all in the mud on the banks?—Yes.

11,592. Are you able to tell us, with regard to each of these matters, where you found them?—I am able to do so with regard to the spiral vessels generally, but I have not separated the spiral vessels of different plants.

11,593. Do you find the spirals at Erith?—Yes.

11,594. And at East Greenwich?—I think so.

11,595. Now with regard to the starch granules—what are they?—They are probably from bread principally, but in some of the mud I have identified wheat-starch and rice-starch, and several specimens of starch, as to which I could not determine the plants from which they came.

11,596. They all seemed to have been through the alimentary canal?—One could not say that with certainty, but probably.

11,597. Where do you find them—in what muds?—I have found them in Crossness, Barking outfall, and Gravesend. I think they might be found probably in many other muds, but I did not look very carefully for them.

11,598. Did you find the wheat-starch looking as if it were partly digested?—Yes, from bread. I noted several granules of starch together, just as one sees them in bread.

11,599. Now, with regard to muscular fibres; those, I presume, come from meat?—Yes, from cooked meat.

11,600. Those are portions which have resisted digestion?—Yes.

11,601. Do you find them more especially from any

particular kind of meat?—I think mostly from beef which has been well cooked, the fibres being rendered hard, and undergoing very little change, probably remaining for months in the same state and often exhibiting delicate transverse markings which are so characteristic that you can distinguish this tissue from anything else.

11,602. Are we to take it that well done beef is more indigestible than anything else?—I should hardly go so far as that.

11,603. (*Chairman.*) May we take that as a caution against eating the brown part of beef—the outside?—It is not so digestible.

11,604. (*Mr. Lumley Smith.*) Are you able to trace the change it has undergone from being in the river longer in some cases than in others?—Yes, some of the fibres are granular—broken up, while those obtained from the sewage itself, or from the banks near the outfall, have a yellow colour, and are very clear and distinct, many containing transverse markings, and several of them retaining the same appearance which they had when passed, and which depends upon partial digestion having taken place.

11,605. (*Sir John Coode.*) Would the length of time they had lain in the mud account for the characteristic markings having disappeared?—I am afraid I can hardly go so far as to say that, but some exhibit the markings and some do not; it is hard to say why, but in some of them, no markings could be seen at first, while by soaking these in glycerine for a time the markings came out.

11,606. (*Mr. Lumley Smith.*) I rather understood you to say that from the mud immediately near the outfalls you find this muscular fibre, in what I may call a more recent condition than you do further off; is that so?—I think it may be so.

11,607. Do you find the muscular tissue in other muds that you have examined?—In a great many; in two muds from Crossness, in three muds from Erith, one mud from Barking outfall, one from Gravesend—in one case very distinctly from sewage taken at the outfall just below Trinity Ballast office; also in a mud taken at East Greenwich, also in mud taken at Blackwall, and also in mud taken at Chelsea.

11,608. And you find this muscular fibre in various conditions of decay?—Yes; but it would be difficult to say, I think, whether that condition of decay depended upon the mere process of digestion, or whether it was due to being macerated for a long time upon the banks, owing to the slow action of the water.

11,609. However, there you found it?—Yes.

11,610. (*Chairman.*) Could you at all tell us this. Suppose you took a pint measure full of the stuff brought to you, could you say what proportion of the contents were fæcal matter?—No, but it would be a very small portion.

11,611. (*Mr. Michael.*) Have you made any quantitative determinations of these various matters?—No, it would be impossible.

11,612. (*Chairman.*) Would you say $\frac{1}{1000}$th part of bulk?—I should think more than that.

11,613. Could you tell us from what was brought to you, whether, as it was taken from the river, one part was lower than the other, that is to say, suppose you took a spade full and got up a quantity, could you tell from what was brought to you, that a part of what was brought to you was the lower part, and part the upper?—I do not think I could.

11,614. It was not brought to you in such a condition that you could tell?—No.

11,615. At all events you could not say how much more than $\frac{1}{1000}$ part was fæcal matter?—No.

11,616. But could you say of the other $\frac{999}{1000}$ parts that they were not fæcal?—I could; they were principally sand—the bulk of the fæcal matter would be very small.

11,617. I thought it possible that there might be a large part of the remainder that you could not attribute to any particular source.

11,618. (*Sir John Coode.*) But the sand would not surely be in the proportion of $\frac{999}{1000}$?—I have not examined it with that view, but I have been astonished at the small amount of organic matter in proportion to the amount of mineral matter.

11,619. (*Chairman.*) Was that because you expected to find more, or because the smell and appearance indicated more?—Because the smell and the appearance indicated a great deal.

11,620. (*Prof. Williamson.*) Where were your samples taken mostly, from what part of the river?—They were taken at several places between Gravesend and Chelsea; some upon the banks of the river and some at a distance from the bank.

11,621. (*Dr. Stevenson.*) You mentioned the smell and the look; have those muds much smell; what time of the year was this?—This was in November, December, and January. Some smelt; those from Crossness smelt very strongly, while others smelt hardly at all when I got them.

11,622. Did you observe any relation between the smell and the amount of organic matter?—Yes, I think so.

11,623. (*Mr. Lumley Smith.*) But do you get a great deal of smell with very little fæcal matter?—Certainly we do; there may be a small amount of organic matter, but the smell may be very bad.

11,624. (*Prof. Williamson.*) The Commission have been told that the banks of the river have been found in some places to be covered with slimy material, which appears to be of organic origin; have you had such material as that for the purpose of examination with the microscope?—I have not.

11,625. Round Erith it was stated that there was a great deal of slimy matter deposited upon the banks?—I have seen it myself.

11,626. But you did not examine it?—No; it was in the summer that I noticed it, but the samples I examined were taken in the winter.

*Sir John Coode* suggested that it was desirable the Commission should know the precise spots at which the samples were taken.

*Mr. Balfour Browne* stated that he would have that made out.

11,627. (*Mr. Lumley Smith.*) (*To the witness.*) Before we pass from this question of the degree with regard to the mud being offensive in smell, in your judgment, as I understand, it is not necessary for that purpose that the fæcal matter should be there in a large proportion compared to the sand and other matter?—No, a very small proportion may have a very strong smell indeed.

11,628. So with regard to its noxious character, the same observation would apply?—Certainly; the foot of a fly might carry poisonous matter enough to poison a number of people or animals.

11,629. Would the relative proportion vary at different times of the year; I think you told us that it would?—I think so.

11,630. Would it depend at all upon the rate at which putrefaction is going on?—That is to say, the offensive matter evolved during the decomposition of the organic matter in the sewage, certainly.

11,631. I think we have got you now as far as the yellow elastic tissue; is that a substance which resists decomposition very strongly?—Yes, very strongly.

11,632. For how long do you find it resisting decomposition; is it a matter of hours or days, or what?—It is a matter of months.

11,633. Then it will stand for months before it decomposes?—Yes.

11,634. (*Prof. Williamson.*) Even when immersed in such a mixture?—Even when immersed in water.

11,635. (*Mr. Lumley Smith.*) I think you told us that you could identify the fibres from the neck of a sheep, and so on?—Yes, different kinds of yellow elastic tissue, all animal.

11,636. Where do you find those?—At Crossness, Barking Bank, Erith, off the end of the Causeway, from mud in a line with the centre of of the "Cornwall," 50 feet or 60 feet from the edge of the bank: Barking Outfall, Crossness, at the upper outfall, in

*Mr. L. S. Beale, M.B., F.R.S.*

13 March 1883.

sewage taken from an outfall below Trinity Ballast Wharf, and in mud taken at East Greenwich.

11,637. (*Sir John Coode.*) Where is the ballast wharf; what relation does it bear to the sewage outfalls; is it above or below? *The spot was pointed out.*

11,638. (*Mr. Lumley Smith.*) What is the next thing you come to?—Yellow fæcal masses.

11,639. What are they?—They consist partly of fæcal matter with the remains of food not digested, often with particles of sand, which become mixed with them as they are moved up and down by the tide, I think.

11,640. Are they masses which would attract the floating mud of the river, and would be likely to combine with the floating mud in suspension in the river?—I think so; being viscid, sticky stuff, it would.

11,641. The natural suspended matter of the river sticks to those particles and they adhere?—Yes.

11,642. What becomes of them then?—I think the organic constituents gradually undergo disintegration and oxidation.

11,643. Then, I think you find, do you not, some fatty matter and oil globules?—Yes, a good deal of fatty matter, that is to say, a good deal, microscopically speaking. I have not estimated the quantity; you find the fatty matter partly as oil globules and partly as crystals, owing to decomposition.

11,644. Then, I believe, you also find in the mud particles of coal and soot, do you not?—Yes, many; also fibres of paper and white fibrous tissue.

11,645. Now, with regard to these specimens of mud, is there any general conclusions that you came to with regard to the characteristics of these muds and the different sources from which they were brought?—Those near the sewers seem to be the worst, and the very worst of all was taken from a sewer; that is to say, taken from an outfall just below an Trinity Ballast Wharf.

11,646. (*Mr. Michael.*) That is the West Ham sewer outfall, is it not?—That, I am afraid, I do not know. I have it "Next to Baldwin and Hugh, London wharf."

11,647. (*Mr. Lumley Smith.*) I may ask you generally with regard to the 25 specimens that you have examined, do you find the products of sewage in all of them?—I think in all, more or less.

11,648. Those are worst that are nearest to the outfalls, but you do find indications of sewage everywhere?—Yes, even at Gravesend and Chelsea.

11,649. Now I want to ask you a question or two upon other points. What is a diatom?—A diatom is a low vegetable organism.

11,650. It is something that is alive, is it?—It is something which is alive, but it has scales composed of silica, which resist decomposition for any conceivable length of time.

11,651. Have you found fragments of diatoms in the mud?—In every specimen of mud.

11,652. I believe a gentleman of the name of Roper wrote a book upon them, did he not?—He wrote a paper upon them in the Transactions of the Royal Microscopical Society, new series, volume 2, page 567.

11,653. What I want to ask you is this; there are certain diatoms which are found in fresh water, are there not?—There are.

11,654. And some in brackish water?—Yes.

11,655. And some in sea water?—Yes.

11,656. If you get fragments of diatom you can tell whether they have come from sea water, or brackish water, or fresh water?—In many instances.

11,657. I believe Mr. Roper gives 104 species from mud off the Isle of Dogs?—Yes, 30 being marine, 29 from brackish water, and the remaining 45 being of the fresh water species.

11,658. Are you able to give us any examples of marine diatom refuse being found in the fresh water districts, and *vice versâ*?—Yes, that has been done. Mr. Roper himself makes a statement to that effect.

11,659. What is the conclusion he comes to?—At Hammersmith 29 were fresh water species out of 43, the remainder being sea water.

11,660. What were found at Gravesend?—Out of 47 specimens only eight were peculiar to fresh water.

11,661. So that they are mostly either diatoms of brackish water, or of the sea?—Yes.

11,662. The figures show that the water is of a decided salt water character up as high as Hammersmith?—Yes, 14 of them being salt water specimens.

11,663. (*Chairman.*) What is the conclusion which you draw from that?—That sea water gets up to Hammersmith, or even farther than that, to Teddington, I believe.

11,664. (*Mr. Lumley Smith.*) So that from the actual diatomaceæ you can see that the sea water has a decided effect up as far as Hammersmith, or farther?—Farther than Hammersmith, I believe.*

11,665. These creatures have silicious shells, have they not?—Yes, they have.

11,666. And they are very light?—Yes.

11,667. What becomes of them when they die?—The organic part is dissolved out; it is decomposed. The siliceous shells remain.

11,668. Do they go in any considerable amount to form the mud of the Thames?—Not to form the mud of the Thames in any considerable amount, but you would find fragments of them in any mud.

11,669. We have had some evidence given about bacteria, and questions were asked as to whether the sewage would be in any way destroyed by the bacteria. Now bacteria are not large creatures, I believe?—They are the hundred thousandth part of an inch in diameter, or less.

11,670. Are they peculiar to sewage?—By no means, they are everywhere.

11,671. With regard to human beings, are they subject to bacteria?—Everywhere; in every tissue; in the blood; in every part of the body in health and in disease.

11,672. Do you suggest that we are all full of bacteria?—I do.

11,673. Are those creatures alive?—They are, or their germs.

11,674. They are found everywhere, in the air, and in the water?—They are found everywhere, and on everything.

11,675. Then I suppose you find them in sewage, and in water, and everywhere?—Undoubtedly.

11,676. When the sewage is poured out into the Thames, I presume, from what you have said, that to a certain extent its putrefying or its decomposition is assisted by bacteria—what is your view about it—to what extent do the bacteria have any effect upon the sewage, because it is suggested that the bacteria would eat up all the sewage?—I am afraid they will not grow fast enough, particularly at this time of the year. If time were allowed, and if the temperature were sufficient for them to grow very rapidly indeed, they would decompose the sewage, and reduce it to something perfectly innocuous, but that would involve an enormous number and enormous time, and a very thin layer of the organic material spread over an enormous surface.

11,677. It is not likely to take place, as the sewage is thrown into the river now?—No; certainly not.

11,678. (*Sir John Coode.*) It is not sufficient to have any practical effect upon the sewage, as it is thrown into the river day by day?—Not practically.

(*Mr. Michael.*) I may say that there has been no suggestion of the kind upon this side of the table.

* See table at the end of Evidence.

Cross-examined by Mr. Michael.

11,679. As I understand you, your investigation has been confined to these 25 specimens of mud?—It has.

11,680. You have not examined, have you, the suspended matter in the Thames water?—I have not.

11,681. Therefore you are unable to speak to what are the living agencies at work eating up the sewage?—Except as regards the bacteria.

11,682. I do not mean bacteria—you are perfectly aware that there are much larger organisms developed in matter of an organic character, which tend to destroy it?—I was not aware of any organisms which would go up and down the Thames and destroy the sewage; but I have examined water with mud in suspension many times, and I never saw any organic beings existing in water that would be likely to destroy the suspended matter of sewage.

11,683. Did you find a large number of desmids and diatoms in the mud?—I did.

11,684. Did you find a large quantity of algæ present?—I did not find a large quantity of algæ, but some algæ.

11,685. Did you take the trouble to discover what is the nature of the superficial matter to be found on the mud?—No, the mud was brought to me in bottles, so I had not the opportunity of examining the surface.

11,686. You had not the means of examining the mud at varying depths?—No, not in this inquiry.

11,687. You made no quantitative examination at all?—No.

11,688. Did you find in your examination the hairs of oats?—Yes.

11,689. Now, a number of these vegetable matters would be found in the detritus washed into the Thames?—Yes.

11,690. For instance, the spiral vessels and the hairs of oats would be washed into the Thames along with the road detritus?—Yes, but one finds the spiral vessels and certain very stable, vegetable, and animal tissues most abundant in the sewage in the mud banks near the openings of the sewers, and no vegetables will grow there.

11,691. But there are vegetables to be found, are there not, in every specimen, that is to say, salt water and fresh water algæ?—Yes, but not of the class of algæ one finds in very fresh water streams.

11,692. Shall I put it "brackish"?—I think not.

11,693. Have you, or have you not, found algæ in the various specimens you have examined?—I found algæ, but extremely few; not nearly so many as you would find in an ordinary stream in the country.

11,694. Have you looked at the character of the mud itself in situ?—No, not upon the Thames.

11,695. Then you have not observed the slimy appearance of which we have heard?—I have not inquired into that at all.

11,696. Is it not the fact, with regard to the envelope of these spirals, that they are likely to be turned yellow through a great many other causes than passing through the intestinal canal?—I think not.

11,697. Have you ever seen spiral vessels in peaty water?—Yes. I have.

11,698. Is it not the fact that where any such pass through peaty water they become coloured in the way you describe?—Yes, but the spiral vessels found in peaty water are entirely different from those found in the mud of the Thames; many of the spiral vessels here are from the common cabbage, and they are very much larger than those found in peaty water.

11,699. You would expect that ordinary detritus would contain a very large quantity of spirals, would you not?—I should not.

11,700. Have you examined ordinary detritus?—I have, but not recently. You find some in it; there are some in straw; but the spiral vessels of straw are totally different from those of cabbage.

11,701. Have you examined the spiral vessels brought down with the sewage from the storm overflows?—No, I have not.

11,702. Are you able to say that the whole of the spiral vessels which you found in the mud were the production of sewage matter being deposited upon the banks?—I am able to say that many of the spirals I found in the mud banks came either from cabbage or from plants closely resembling cabbage, or from turnips, or from carrots, or from tea-leaves; those may be, I think, identified.

11,703. But you have no idea either how much the organic matter formed of the whole, or how much the spirals formed of the matter that you examined?—That I cannot say.

11,704. (*Sir Benson Maxwell.*) From the appearance of the spirals, could you say whether they had passed through the alimentary canal or not?—No; they may have been boiled.

11,705. We had some evidence that the spirals in passing through the alimentary canal, lose the outer envelope?—That is so.

11,706. Is it only by passing through the alimentary canal that they lose the outer envelope?—By prolonged boiling you get the same effect.

11,707. (*Dr. Stevenson.*) What would be the effect of prolonged maceration in cold water?—I think it would be the same as of passing through the alimentary canal.

11,708. (*Dr. de Chaumont.*) How do you recognise the yellow masses as being from sewage?—They have this distinctive character, that they can be broken up and squeezed between glass, and the yellow matter squeezed out, whereas the yellow matter from vegetables is usually hard and cannot be squeezed, and the yellow matter is distinct. I have frequently seen yellow matter, which I should not put down as fæcal.

11,709. Is there any chemical re-action?—No, I have not been able to get any chemical re-action, but you can tell by the eye.

11,710. If you met with iron in the form of oxide suspended, do you think that would be liable to lead you to error in respect of the colour?—I think it would be quite impossible to make any mistake of that kind, even without the chemical re-agent, because the colour and the appearance would be different, and the hardness of the material would be different. I have compared those which one calls fæcal masses in sewage with actual fæcal masses, and they look exactly alike.

11,711. (*Sir John Coode.*) You think you can detect, without any doubt or question, those vessels which have actually passed through the human body?—Musular fibre, without doubt or question, and yellow elastic tissue, without doubt or question; the other things I think not without some doubt.

Re-examined by Mr. Lumley Smith.

11,712. Although you are unable to say whether those spirals have passed or not through the alimentary canal, they have been certainly cooked?—They have been certainly cooked. Prolonged boiling would produce the same effect.

11,713. (*Dr. Stevenson.*) But you said something about maceration; would simple maceration in cold water have the same effect?—I think that the soft spiral vessels, if they were macerated a sufficiently long time in cold water, would have the spirals separated.

11,714. (*Mr. Lumley Smith.*) I think you stated you had not examined the slimy mud for the purpose of microscopic investigation?—I have not.

11,715. But you have seen the black mud?—Yes.

11,716. And you have seen it in the summer?—Yes.

*Mr. L. S. Beale, M.B., F.R.S.*

13 March 1883.

*(The witness handed in the following list of stations where the mud was taken from.)*

November 16th 1882.

Present:
W. Collingridge, Inspector Lewis, } Wind N. by E.

High water, London Bridge, 4.52.
Snow.

SAMPLE MUD.

SAMPLE of MUD taken fron Bed of RIVER.

| No. | REMARKS. |
|---|---|
| 1 | Centre of Southern Outfalls Station, Crossness, in a line with the end of the Jetties. Time. 12.45 a.m. |
| 2 | Off Crossness, about 20 feet from wall, midway between upper Jetty and upper end of River Wall. Time 12.50 a.m. |
| 3 | 100 feet above house above Powder Magazine, Half-way Point, a few yards from the shore, lower edge of the so-called Barking Bank. |

These were taken by Dr. Collingridge.
Taken to Dr. Beale.
INSPECTOR LEWIS.

November 24th 1882.

Present:
W. Collingridge, Inspector Lewis, } Wind fresh, N.W.
High water, London Bridge, 1 p.m.

SAMPLE MUD.

SAMPLES of MUD taken for DR. BEALE by W. COLLINGRIDGE.

| No. | REMARKS. |
|---|---|
| 4 | Off Erith.—Off Causeway Corinthian Yatch Club, 20 yards from shore. Time 1.26 p.m. |
| 5 | Erith.—Off Town Causeway about 30 yards from River walls. Time 1.37 p.m. |
| 6 | Erith.—Opposite Easton and Anderson's Works, about 70 feet from shore. Time 1.44 p.m. |

Taken to Dr. Beale.
INSPECTOR LEWIS.

4th December 1882.

Wind, west. Fresh. Cloudy.
High water, London Bridge, 8.30.

SAMPLES OF MUD.

Taken for DR. BEALE by INSPECTOR LEWIS.

| No. | Time. | REMARKS. |
|---|---|---|
| 7 | 2.15 | In a line of the stern of the "Cornwall" off the shore about 90 feet from edge of bank. |
| 8 | 2.25 | In a line with centre of the "Cornwall" about 50 feet or 60 feet from the edge of bank. |
| 9 | 1.15 | About 100 feet below Conservancy Causeway, Greenhithe, and about 100 feet from the shore. |
| 10 | 1.30 | About 100 feet from the Quay Centre of Ballast Wharf, by the Arethusa. |

Removed to Dr. Beale's, 5th December.

15th December 1882.

Wind, east. Very foggy.
High water London Bridge, 4.43.

SAMPLES OF MUD.

Taken for DR. BEALE by INSPECTOR LEWIS.

| No. | Time. | REMARKS. |
|---|---|---|
| 11 | 1.25 | Beckton, in a line with the Clock Tower, about 80 to 90 feet from Quay. |
| 12 | 1.35 | Barking Outfall, about 40 feet below outfall in a line with the lower corner of the station off the shelve piece. |
| 13 | 1.45 | Barking. At the lower end of the Metropolitan Board of Works Grounds, and about 100 feet from the Bank. |

Removed to Dr. Beale's 16th instant.

4th January 1883.

Wind, S.E., light.
High water, London Bridge, 9.22.

SAMPLE MUD.

Taken at GRAVESEND for DR. BEALE.

| No. | Time. | REMARKS. |
|---|---|---|
| 14 | 1.50 | Midway between the Customs Causeway and the Conservancy, about 30 feet from the River end of Causeway, nearly low water (Causeway is 160–180 feet in length). |
| 15 | 2.15 | Opposite the lower end of the "Clarendon" Hotel, in a line with the Terrace Pier Head. |
| 16 | 2.35 | Just below the Club House, about 80 feet from Coal Wharf Quay, and in a line with the end of that Quay. |

INSPECTOR LEWIS.

10th January 1883.

Wind moderate, Easterly.
High water, London Bridge, 2.27 a.m.

SAMPLE MUD.

Taken for DR. BEALE by INSPECTOR LEWIS.

| No. | Time. | REMARKS. |
|---|---|---|
| 17 | 8.0 | Crossness. At the Upper Outfall taken from the bed of the River. |
| 18 | — | From a bank at the upper end of the Upper Jetty at Crossness. |
| 19 | 9.0 | Right off the centre of Barking Outfall, about 120 feet from the arches. |
| 20 | 10.0 | At a sewer by the steps just above Woolwich Pier. |

INSPECTOR LEWIS.
Sent to Dr. Beale 10th January 1883.

11th January 1883.

Wind, S.E., light.
High Water, London Bridge, 3.?.

SAMPLE MUD.

| No. | Time. | REMARKS. |
|---|---|---|
| 21 | 11 a.m. | Taken from an outfall just below the Trinity Ballast Office, Limehouse, and next to Baldwin and Hugh London Wharf. |

INSPECTOR LEWIS.
Taken to Dr. Beale.

17th January 1883.

Wind, W., light, dull. Rain early morning.
High Water, London Bridge, 7.44.
SAMPLE MUD.

| No. | Time. | Remarks. |
|---|---|---|
| 22 | 11.40 | Taken at East Greenwich off Messrs. Rowton and Whiteway's Wharf, about 100 feet below the Harbour Master's Causeway, and about 40 to 50 feet from the Quay. |
| 23 | 2.50 | Blackwall.—At the lower side of the Upper Pier Head of the South West India Dock Blackwall entrance, about 4 feet from the pier and about 40 feet from the pier head. |

18 January 1883.

Wind, moderate, S.W., with Rain.
High Water, London Bridge, 8.53.
SAMPLE MUD.

Taken near Waterloo and Chelsea.

| No. | Time. | Remarks. |
|---|---|---|
| 24 | 1.15 | (South Shore) opposite the Saw Planing Works, about 200 or 250 feet above Charing Cross Railway Bridge, and about 100 feet off the Quay. |
| 25 | 2.15 | Chelsea, North Shore, opposite the Aquatic Stores, and about 70 feet off the Quay, and about 400 or 500 feet below Randall's Coal Wharf (near midway between Battersea Old Bridge and the Wharves Creek, Cremorne Wharf. |

Inspector Lewis.
Taken to Dr. Beal

*Mr. L. S. Beale, M.B., F.R.S.*

13 March 1883.

The witness withdrew.

*Dr. Beale* subsequently put in the following list of Diatoms found in the mud of the Thames; it is taken from a paper by Dr. Bossey, of Red Hill, and published in the proceedings of the Holmesdale Natural History Club:

A List of Fresh and Salt Water Diatoms found in Mud Banks in the River Thames, compiled for the purpose of showing the influence of the Flood and Ebb Tides in forming those Banks.

| Marine Diatoms in small capitals. Fresh Water Diatoms in ordinary type. | Half a Mile above Teddington Lock. | Teddington Cut. | One Mile below Teddington Lock. | Kew. | Blackwall. | Estuary of the Thames, Sheerness. |
|---|---|---|---|---|---|---|

SUMMARY.

| | Half a Mile above Teddington Lock. | In Teddington Cut. | One Mile below Teddington Lock. | Between Richmond and Twickenham.† | Kew. | Blackwall. | Estuary of the Thames. |
|---|---|---|---|---|---|---|---|
| Ebb Tide runs ⟩⟩⟩

where you took the samples, and how it was done?—Yes.

11,737. (*Mr. Michael.*) Did you take them in the same manner as the last witness?—Yes.

11,738. (*Mr. Balfour Browne.*) Did you take them in exactly the same way?—Yes.

11,739. This diagram corresponds with Professor Way's description.

*Mr. F. J. Short.*
13 March 1883.

Cross-examined by Mr. Michael.

11,740. This sample was taken at high water, was it not?—They were taken at high water, and low water.

11,741. How did you manage at low water?—They were taken in the same positions as they are shown there, the river was divided into four parts.

11,742. (*Sir Benson Maxwell.*) How did you know when it was high water, or low water when you took the samples?—We moored the boat to a dolphin of the pier, and scratched marks upon one of the piles until the water lowered no more in the case of low water, and rose no more in the case of high water. There was then slack water for a short time, and it was during that time the samples were taken.

11,743. (*Mr. Michael.*) What was the depth at which you took the samples at low water?—At 20 feet, in the middle of the river.

11,744. Was that 20 feet at each of these points?—No, only in the middle of the river. I do not know what the depth at the other places was, but they were taken about a foot from the bottom.

11,745. How do you know where the samples were taken as regards the bottom of the river?—Because I had a heavy weight which I lowered to the bottom.

11,746. Until it touched the bottom?—Yes.

11,747. How long afterwards did you take the sample?—The sample was taken at the same time; the bottle was lowered upon the string, with a cord tied to the stopper.

11,748. (*Sir Benson Maxwell.*) You would strike the bottom with the lead?—It did not *strike* the bottom; it was lowered quietly on to it.

11,749. And that would disturb the mud, would it not?—I do not know whether it would.

11,750. That would depend upon the solidity of the mud?—But the bottle being a foot, or a foot and a half above the surface of the mud, I do not know whether it would in any way affect the samples.

11,751. (*Mr. Michael.*) How long did it take to take the samples?—They were taken in a quarter of an hour.

*Mr. Michael* stated that he wished to have evidence about the taking of samples at Gravesend and Southend, and that he only wished to know how the water was collected, the absolute position from which the water was taken, and the time occupied in taking the samples.

The witness withdrew.

Dr. Collingridge called in and examined.

11,752. (*Mr. Michael.*) What interval elapsed between the various times of taking the waters?—In no case except Southend more than a quarter of an hour between the first samples, and the last.

11,753. But how many samples were taken at Gravesend?—At Gravesend there were three samples taken.

11,754. (*Sir John Coode.*) Were you present when they were taken?—I was not.

11,755. (*Mr. Lumley Smith.*) You are speaking from each label which had the time upon it, at which it was taken, so that a comparison of the labels would enable you to judge of the interval of time between taking the first sample, and the last of the section?—Yes, I can speak to that, and in no case with the exception of Southend was the time occupied in taking the samples, more than 15 minutes in each place.

11,756. (*Mr. Michael.*) How many boats were there employed at Gravesend?—There was one boat manned by two men.

*Dr. Collingridge.*

11,757. Is it possible that those specimens could have been taken in 15 minutes?—Yes, because the men only had to row half across the river.

(*Sir John Coode.*) How many specimens were taken?

(*Mr. Michael.*) Six specimens, three were taken at 20 feet below the surface, and three at the surface.

(*Witness.*) The river is divided into four different divisions, so that there are three spaces.

*The witness explained to the Commissioners upon the diagram that it would be exactly half of the river that would have to be crossed.*

The witness withdrew.

Mr. Baldwin Latham, Mem. Inst. C.E., re-called and further examined.

11,758. (*Mr. Lumley Smith.*) Will you refer to that part of your examination at which certain tables were promised?—It was put to me in cross-examination that instead of there being 10 parts of chlorine in 100,000 parts in sewage there were 20, and I then stated that it would make very little difference indeed with regard to the mixing action; but I promised to work out the result at 20 parts and put the tables in. I have prepared them in the same form, and beg to hand them in. Practically in the way in which I have dealt with it (I have put the results into two small tables, A. and B.) (*These were handed in, and are as follows.*)

*Mr. B. Latham, M. Inst. C.E.*

*Mr. B. Latham, M. Inst. C.E.*

13 March 1883.

## A.

TABLE showing the EFFECT of the MIXING ACTION in the RIVER THAMES.

Time occupied by Fresh Water and Sewage in traversing River.

The results are obtained by taking sewage as containing 10, river water 1·7, and sea water 1961 parts of chlorine in 100,000 parts. In this case the upland water is apportioned to every section of the river which it enters.

| Deptford to N. Woolwich | 6·52 | 3·37 | 4·94 | 4·19 | 2·78 | 3·48 | 1·50 | ·64 | 1·07 |
| N. Woolwich to Barking | 2·47 | 1·38 | 1·93 | 1·61 | 1·15 | 1·38 | ·61 | ·28 | ·44 |
| Barking to Crossness | 3·78 | 2·14 | 2·96 | 2·64 | 1·86 | 2·25 | 1·08 | ·52 | ·80 |
| Crossness to Erith | 3·88 | 2·60 | 3·24 | 2·89 | 2·23 | 2·56 | 1·29 | ·70 | 1·00 |
| Erith to Gravesend | 12·70 | 11·34 | 12·02 | 10·37 | 9·48 | 9·93 | No samples taken at Gravesend. | | |
| Gravesend to Southend | 12·04 | 20·16 | 16·10 | 12·71 | 14·47 | 13·59 | 12·57 | 11·75 | 12·16 |
| Total | 53·94 | 45·44 | 49·69 | 41·66 | 35·56 | 38·61 | 12·40 | 14·84 | 17·12 |
| Deptford to Southend | 41·39 | 40·99 | 41·19 | 34·41 | 31·97 | 33·19 | 17·05 | 13·89 | 15·47 |

I find, taking the number of days required for the sewage to pass out of the river, that it only makes a difference in some instances in the second place of decimals. Upon the 14ih of September at high water, taking the whole distance from Deptford to Southend with 10 parts, it would be 41·38 days and with 20 parts it would be 41·39 days. And the same at low water, you have a result of 40·97, which becomes 40·99, that is taking the 14th of September; and so with regard to all the rest of the days. There is another point I should like to mention, which I omitted at the time, and that is with regard to the solid matter. I am referring now to my answer to question 8064. All I wish to state is this, that the solid matter which I was speaking of with regard to the sewage, the 200,000 tons a year passing into the Thames is absolutely dry matter. But that is compared with the saltings of the river which are taken out in cube yards, and calculated that a cube yard in its natural state would weigh a ton. We are here comparing dry matter with matter which contains 40 per cent. of water; so that the absolute dry matter in the saltings would be very much less than 41,417 tons, and the ratio of the dry matter of the sewage would be very much greater; and would be more than six times as much as the dry matter of the saltings.

The witness withdrew.

SIR P. BENSON MAXWELL TOOK THE CHAIR.

Professor W. H. CORFIELD, M.D., called in and examined.

11,759. (*Mr. Balfour Browne.*) You are Professor of Hygiene at University College?—I am.

11,760. And you are Doctor of Medicine of Oxford and an Examiner at Cambridge?—Yes.

11,761. Have you examined the condition of the lower Thames and the outfalls of the metropolitan sewers?—I have.

11,762. Do you remember the date when you made your examination?—It was in 1878, on October 16th, I think.

11,763. It was shortly, I think, after the sinking of the "Princess Alice"?—Yes, the "Princess Alice" went down upon the 3rd September.

11,764. The sewer outfalls at the time of your inspection were discharging, were they not, into the river?—Yes.

11,765. Both at Barking and Crossness?—Yes, at both places.

11,766. And on those occasions when you inspected, which way was the sewage flowing?—The sewage was flowing up stream.

11,767. Both from Barking and Crossness?—Yes.

11,768. From Crossness did you follow the stream of sewage?—Yes, I followed it in a boat for about three quarters of a mile.

11,769. Was the sewage marked distinctly upon the surface of the river?—It was.

11,770. What by?—By the floating material upon the surface of the water.

11,771. Was the stench bad at either of the outfalls upon that day?—It was very bad indeed at both the outfalls.

11,772. Did you take samples and specimens in several parts of the river near the outfalls?—Yes, those samples are deposited in the Parkes Museum of Hygiene in Margaret Street, Regent Street.

11,773. As a matter of fact the Museum is not opened to the public at present, but it is to be?—It is to be.

11,774. Did you also take a sample in mid-stream off Woolwich?—I took one sample in mid-stream off South Woolwich.

11,775. Do you remember the time at which the water was collected?—At a little after 12 o'clock, I think.

11,776. You took another sample at Barking?—Yes, I took another sample 100 yards above the Barking outfall at about 5 o'clock in the afternoon.

11,777. Do you recollect the character of the sample collected off Woolwich which you have just spoken about?—It was a highly polluted water.

11,778. Generally, do you recollect how many parts of albumenoid ammonia per 100,000 parts?—0·2, that is to say, a tenth of what there is in sewage.

11,779. Then with reference to the sample that was collected at the Northern outfall, did that consist largely of sewage?—Yes, that contained, if I remember rightly, about 4½ parts of ammonia per 100,000 parts; that is to say, of saline ammonia, not albumenoid ammonia.

11,780. Going back to the South Woolwich specimen, how much suspended matter did that contain?—It contained seven parts per 100,000 of suspended matter, of which 80 per cent. were fixed and 20 per cent. volatile.

11,781. (*Prof. Williamson.*) When you say "fixed" do you mean at 100° centigrade, or do you mean not combustible?—I mean, that on incineration, 80 parts remained that were not volatile. The Barking specimen contained 14·65 parts of suspended matters, of which 40 per cent. were fixed and 60 per cent. volatile.

11,782. (*Mr. Balfour Browne.*) The comparison of the South Woolwich sample with the Barking sample gives you an idea of the condition of the river there as compared with it at Barking where the sewage was being poured in?—Yes.

11,783. Have you taken up samples of mud from various parts?—I inspected the mud at various points. I did not take any away with me.

11,784. What was its character?—It was in most places black, and very foul.

11,785. (*Prof. Williamson.*) Did you notice any sliminess in the mud which you raised from the bottom, or was it loose particles?—Most of it was very slimy.

11,786. (*Mr. Balfour Browne.*) Did you also inquire into the circumstances of some cases of illness?—I did.

11,787. What were they due to?—They were due to the immersion in the water of the Thames at the time of the accident to the "Princess Alice."

11,788. What did you make out of your inquiries into those cases?—

11,789. (*Chairman.*) Did you see the patients yourself?—I did not in either instance.

11,790. (*Sir John Coode.*) Nor the clothing, because we have heard much about the clothes?—I did not; those were cases that came under my notice, and I inquired into the circumstances from their friends and from the medical men who attended them; in one case seven persons were immersed, of whom three were saved, and of these two were taken ill, one, the father, slightly, the other, a boy, five years of age, badly, with what was considered to be a form of pneumonia accompanied with a little diarrhœa, but was believed from the symptoms not to be typhoid fever. The doctor who was attending the case thought that it was not a case of typhoid fever, but the fact was that the nurse who was attending the patient contracted typhoid fever, and died of it. Another case was that of a young lady who was in the water about four or five minutes, when she was rescued by a boat, and then taken to a cottage and put to bed while her clothes were dried. On the 4th September, the day after the accident, she went home and went to bed, suffering from great exhaustion; she remained in bed until about October the 7th, suffering from a form of pneumonia. At the end of the first week of her illness, her temperature rose to 103, and remained at this height continuously for a week, going occasionally up to 105; and she was attacked with severe diarrhœa and became delirious. Those are very obvious symptoms of typhoid fever, Altogether she was in bed about a month. Although the eruption was not observed either in this or in the previous case, I am of opinion that they were both cases of typhoid fever, produced by the water swallowed at the time of immersion; indeed, the description of the latter case is very characteristic of a large number of cases of typhoid fever, accompanied with pneumonia, and in the former case, although the symptoms of pneumonia were most prominent, the fact that the nurse who attended it took typhoid fever, and died of it, is at least a very significant one.

11,791. (*Mr. Balfour Browne.*) The latter case has evidently been very carefully observed by medical men, because the temperature has been observed by them?—Yes; the medical man who attended the latter case is of opinion that it was typhoid fever.

11,792. (*Chairman.*) Who was the medical man who gave you that information?—The medical man was a doctor in Exeter; this lady went home to Exeter, and was attended there.

11,793. (*Mr. Balfour Browne.*) Have you, with the view of ascertaining whether the state of the river produces any effect upon the health of the population upon the banks of the lower Thames, examined the quarterly returns of the Registrar-General?—Yes, I have.

11,794. For how many years?—For 11 years.

11,795. Which years are those?—Those are from 1871 to 1881 inclusive.

11,796. For what district?—For certain sub-districts

*Prof. W. H. Corfield, M.D.*

13 March 1883.

or parts of sub-districts from London Bridge downwards to the Medway, on opposite sides.

11,797. Have you made out tables which you are now going to submit to the Commission?—Yes. (*See Appendix* B.U.)

11,798. You have compiled those tables from the Registrar-General's returns?—Yes, I have.

11,799. What does Table I. show?—That consists of 8 sheets, and it gives the deaths every quarter; it shows the mortality statistics, generally speaking, especially from zymotic diseases, for each quarter during the 11 years in each of the eight districts or sub-districts on the north side of the Thames.

11,800. (*Mr. Michael.*) Will you read the names of the districts?—Beginning with London Bridge upon the north, the districts are a part of Whitechapel, called Aldgate; that includes part of Whitechapel, East Smithfield, Old Tower, Tower Without, and the Tower of London.

11,801. (*Chairman.*) Then there are Limehouse, Poplar, West Ham, East Ham, Barking, Romford, Rainham, Grays, and Thurrock?—Whitechapel is the first; the second is St. George's-in-the-East.

11,802. (*Mr. Balfour Browne.*) What you have read, sir, are the Local Board districts. (*To the witness.*) Your districts are Aldgate, St. Paul, Stepney, Poplar, West Ham, Barking Town, Hornchurch, and Orsett?—Yes, some of those are the Registrar-General's sub-districts, and some of them are the parts of those sub-districts near the river.

11,803. You are trying to find out whether this condition of the river has any effect upon health?—Yes.

11,804. Table II. gives similar results for the south side of the river, does it not?—Yes. That table includes the sub-districts or parts of sub-districts of St. Olave's Southwark, Greenwich, Woolwich, Bexley, Dartford, Northfleet, Gravesend, and Hoo.

11,805. What do Tables Nos. 3 and 4 show?—Tables Nos. 3 and 4 show the annual results for the same districts. (*These are incorporated in the foregoing.*)

11,806. Table No. 3 corresponding with the northern districts, and Table No. 4 with the southern districts?—Yes.

11,807. What do Tables Nos. 5 and 6 show?—Tables Nos. 5 and 6 show the average annual number of deaths from zymotic diseases in each of those sub-districts for the 10 years 1871 to 1880.

11,808. That is both for the north and for the south side of the Thames?—Table No. 5 is for the north, and Table No. 6 is for the south side of the Thames.

11,809. Your next Tables are Nos. 7 and 8?—Yes. (*These were handed in and are as follows*):

TABLE VII.

Zymotic Deaths, Average Annual Results for 10 years 1871–80. Proportions to 1,000 persons living.

North Side of the Thames.

| — | District. | Smallpox. | Measles. | Scarlet Fever. | Diphtheria. | Whooping Cough. | Fever. | Diarrhœa. | Cholera. | Zymotic Death Rate. |
|---|---|---|---|---|---|---|---|---|---|---|
| 1 | Aldgate | 0·42 | 0·46 | 0·66 | 0·04 | 0·82 | 0·40 | 1·27 | 0·04 | 4·11 |
| 2 | St. Paul | 0·17 | 0·73 | 0·58 | 0·10 | 1·17 | 0·37 | 1·12 | 0·03 | 4·27 |
| 3 | Stepney | 0·30 | 0·74 | 0·82 | 0·11 | 1·02 | 0·35 | 1·22 | 0·04 | 4·60 |
| 4 | Poplar | 0·46 | 0·68 | 0·85 | 0·08 | 0·91 | 0·37 | 1·06 | 0·04 | 4·45 |
| 5 | West Ham | 0·57 | 0·40 | 0·75 | 0·06 | 0·58 | 0·30 | 1·02 | 0·04 | 3·72 |

| | London | 0·46 | 0·51 | 0·60 | 0·12 | 0·82 | 0·37 | 0·92 | 0·04 | 3·84 |
| | Eastern Registration Division including the Counties of Essex, Suffolk, Norfolk | 0·18 | 0·17 | 0·40 | 0·11 | 0·43 | 0·35 | 0·72 | 0·02 | 2·38 |

*N.B.—This sub-district chiefly consists of places at a considerable distance from the river.

TABLE VIII.

Zymotic Deaths, Average Annual Results for 10 years 1871–80. Proportions to 1,000 persons living.

South Side of the Thames.

| — | District. | Smallpox. | Measles. | Scarlet Fever. | Diphtheria. | Whooping Cough. | Fever. | Diarrhœa. | Cholera. | Zymotic Death Rate. |
|---|---|---|---|---|---|---|---|---|---|---|
| 1 | St. Olave, Southwark | 0·26 | 0·59 | 0·81 | 0·18 | 1·08 | 0·40 | 1·07 | 0·07 | 4·46 |
| 2 | Greenwich | 0·57 | 0·48 | 0·53 | 0·11 | 0·65 | 0·43 | 0·89 | 0·03 | 3·69 |
| 3 | Woolwich | 0·12 | 0·55 | 0·61 | 0·19 | 0·61 | 0·36 | 0·73 | 0·50 | 3·22 |
| 4 | Bexley* | 0·08 | 0·25 | 0·55 | 0·08 | 0·36 | 0·31 | 0·54 | 0·03 | 2·20 |
| 5 | Dartford | 0·41 | 0·38 | 0·53 | 0·19 | 0·35 | 0·25 | 0·59 | 0·07 | 2·77 |
| 5 | Northfleet | 0·40 | 0·38 | 0·88 | 0·10 | 0·40 | 0·49 | 0·74 | 0·04 | 3·43 |
| 7 | Gravesend | 0·20 | 0·22 | 0·67 | 0·05 | 0·52 | 0·36 | 0·80 | 0·06 | 2·88 |
| 8 | Hoo | 0· | 0·09 | 0·12 | 0· | 0·37 | 0·98 | 0·92 | 0·15 | 2·63 |
| | London | 0·46 | 0·51 | 0·60 | 0·12 | 0·82 | 0·37 | 0·92 | 0·04 | 3·84 |
| | South-Eastern Registration Division, including the Counties of Surrey, Kent, Sussex, Hampshire, Berkshire | 0·10 | 0·24 | 0·31 | 0·14 | 0·37 | 0·33 | 0·62 | 0·02 | 2·13 |

*N.B.—This sub-district largely consists of places at a considerable distance from the river.

11,810. Do they give the average death rate from each of the zymotic diseases and from them altogether per 1,000 persons living in the same 10 years?—Yes.

11,811. Do they show anything else?—Yes, they also show a corresponding number for London and for the registration divisions of England in which the sub-districts or districts are.

11,812. So that now you have the means of comparing the death-rate of those places with London and with the registration divisions to which they belong respectively?—Yes, with the eastern registration division, including the counties of Essex, Suffolk, and Norfolk, and with the south-eastern registration division, including the counties of Surrey, Kent, Sussex, Hampshire and Berkshire.

11,813. Now with regard to Tables Nos. 9 and 10, what do they show?—They show the density of population in 1871 and in 1881 in each of those districts, on both sides of the Thames. (*These were handed in and are as follows*):—

TABLE IX.

DENSITY of POPULATION in 1871 and in 1881, NORTH SIDE of the THAMES.

| | District. | Area in Acres. | Population, 1871. | Population to each Acre, 1871. | Population, 1881. | Population to each Acre, 1881. |
|---|---|---|---|---|---|---|
| 1 | Aldgate - - | 87 | 9,224 | 106·0 | 6,092 | 70·0 |
| 2 | St. Paul - - | 84 | 21,350 | 254·1 | 20,620 | 245·4 |
| 3 | Stepney - - | 462 | 57,690 | 124·8 | 58,500 | 126·6 |
| 4 | Poplar - - | 2,335 | 116,376 | 49·8 | 156,525 | 67·0 |
| 5 | West Ham - | 7,051 | 44,642 | 6·3 | 101,024 | 14·3 |
| 6 | Barking Town - | 3,814 | 6,576 | 1·72 | 9,155 | 2·4 |
| 7 | Hornchurch - | 19,482 | 6,979 | 0·36 | 7,196 | 0·37 |
| 8 | Orsett - - | 41,167 | 13,172 | 0·32 | 16,356 | 0·40 |
| | London - - | 75,362 | 3,254,260 | 43·2 | 3,814,571 | 50·6 |
| | Eastern Registration Division. | 3,211,441 | 1,218,728 | 0·38 | 1,342,923 | 0·42 |

TABLE X.

DENSITY of POPULATION in 1871, and in 1881, SOUTH SIDE of the THAMES.

| | District. | Area in Acres. | Population, 1871. | Population to each Acre, 1871. | Population, 1881. | Population to each Acre, 1881. |
|---|---|---|---|---|---|---|
| 1 | St. Olave, Southwark. | 1,268 | 89,902 | 70·9 | 102,646 | 80·9 |
| 2 | Greenwich - | 3,426 | 100,600 | 29·4 | 131,264 | 38·3 |
| 3 | Woolwich - | 6,500 | 73,380 | 11·3 | 80,782 | 12·4 |
| 4 | Bexley - - | 12,541 | 19,566 | 1·6 | 24,137 | 1·9 |
| 5 | Dartford - | 16,968 | 16,466 | 0·97 | 22,239 | 1·3 |
| 6 | Northfleet - | 20,176 | 10,474 | 0·52 | 12,728 | 0·63 |
| 7 | Gravesend - | 1,256 | 21,265 | 16·9 | 23,375 | 18·6 |
| 8 | Hoo - - | 19,859 | 3,143 | 0·16 | 3,397 | 0·17 |
| | London - - | 75,362 | 3,254,260 | 43·2 | 3,814,571 | 50·6 |
| | South-Eastern Registration Division. | 3,994,431 | 2,167,726 | 0·54 | 2,486,151 | 0·62 |

11,814. And also in London?—And also in London, and also in the eastern registration division for comparison with the north side of the Thames, and the south-eastern registration division for comparison with the south side of the Thames.

11,815. Then you have also Table No. 11 which shows the corresponding figures with regard to Dagenham?—Yes. (*The same were handed in and is as follows*):—

TABLE XI.

ZYMOTIC DEATHS.

Numbers for 11 years, 1871-81. 6 × N, Sub-district, 180, Romford.

Division, Romford.
Place Dagenham, Population 1871, 2,879—1881, 3,411.

| Year. | Smallpox. | Measles. | Scarlet Fever. | Diphtheria. | Whooping Cough. | Fever. | Diarrhœa. | Cholera. | Zymotic Total. |
|---|---|---|---|---|---|---|---|---|---|
| 1871 - | 6 | 1 | 1 | 0 | 2 | 2 | 3 | 0 | 15 |
| 1872 - - | 1 | 0 | 0 | 0 | 2 | 2 | 5 | 0 | 10 |

Average Annual results for ten years, 1871-80. Proportions to 1,000 persons living.

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| 9·22 | 0·09 | 0·33 | 0·06 | 0·45 | 0·26 | 0·99 | 0 | — | 3·00 |

Density of the Population.

| Area in Acres. | Population, 1871. | Population to each Acre. | Population in 1881. | Population to each Acre. |
|---|---|---|---|---|
| 6,556 | 2,879 | 0·44 | 3,411 | 0·52 |

11,816. Will you tell us why that has been taken separately?—The figures with regard to Dagenham were taken separately for this reason; two parts of the Romford sub-district were taken, namely, Barking Town and Hornchurch, which both belong to the registration sub-district of Romford. The part in which Romford itself is, I did not take, because it is a large town and away from the river. When I had done that, I found that part of that division of Romford which includes the town of Romford, comes down to the Thames and includes a considerable part of the Thames side; that part is called Dagenham; and it was impossible to get the figures of Dagenham separately from Romford from the Registrar-General's Returns; but I have got those figures by going to the original returns of the local places.

11,817. You mean you went to the tables which are sent in originally from the local places to the Registrar-General, and from which his tables are made up?—Yes. Now I have Tables Nos. 12 and 13.

*Prof. W. H. Corfield, M.D.*

13 March 1883.

## TABLE XII.

9 N. Rochford. 193.

Divisions.—Rayleigh and Prittlewell.

Including the Parishes of Rawreth, Hockley, South Fambridge, Eastwood, Rayleigh, Thundersley, South Benfleet, Hadleigh, Leigh, Prittlewell, Southchurch. Population 1871, 11,673; 1881, 15,199.

Average annual Number of Births and Deaths, and Rates per 1,000 Persons living, for Ten Years, 1871–80.

| Births. | Birth-rate. | Deaths. | Death-rate. | Deaths under 1. | Deaths at 60 and upwards. | Smallpox. | Measles. | Scarlet Fever. | Diphtheria. | Whooping Cough. | Fever. | Diarrhœa. | Cholera. | Zymotic Total. | Zymotic Death-rate. |

|---|---|---|---|---|
| 22,430 | 11,783 | 0·52 | 12,101 | 0·54 |

11,818. What do they show?—Table 12 contains similar statistics as far as zymotic diseases are concerned, and the density of the population, for another division upon the north side, namely, Rochford, still further down the river.

11,819. Rochford includes Southend, does it not?—Rochford includes two large towns, namely, Southend and Rayleigh. Table No. 13 gives similar numbers for two districts upon the south side further down the river.

11,820. So that with those tables you have prepared you have a complete series of statistics from London to Southend, upon either side of the river?—Yes, it is farther than Southend; it is in two parts, one to the Medway and opposite to it, or thereabouts, and another which has been done afterwards for the lower portion of the river. I shall have printed copies of the tables ready by to-morrow.

11,821. Tables 1 to 6 show the annual number of deaths from zymotic diseases during the 10 years from 1871 to 1880; is that so?—Tables 1 to 4 show the absolute numbers.

11,822. And from those numbers in Tables Nos. 5 and 6, you have calculated the average?—The average annual numbers in the 10 years.

11,823. From Tables 7 and 9, what appears with regard to the north side of the Thames?—Table 7 shows that the average zymotic death rate upon the north side of the Thames in six of those districts, is either above what it is in London, or very nearly approaches the zymotic death-rate in London.

11,824. In the first four districts the death-rate is either higher than the London death-rate, or closely approaches to it?—In the first four districts upon the north side it is all higher than the death-rate in London, and in the last four districts it is decidedly higher than the death-rate in the eastern registration division, with one exception.

11,825. The eastern registration division being that of which they form a part?—Yes.

11,826. What is the exception to which you allude?—Hornchurch. There the zymotic death-rate is almost exactly the same as it is in the eastern registration district; but Hornchurch contains no town; it consists mostly of scattered villages at a distance from the river.

11,827. That is the only instance in which the death-rate goes down?—That is the only instance where the death-rate from zymotic diseases is as low, or nearly as low, as it is in the eastern registration division.

11,828. That is to say, it is more of the character of the eastern registration division and less of a riparian character?—I should go further than that, because in the eastern division there are a good many large towns, while there are no large towns in Hornchurch.

11,829. Therefore you find that health is affected by contiguity to the river all the way down upon the north side?—The fact is, that the zymotic death-rate all the way down upon the north side is higher, as I said, than it is in the eastern registration division.

11,830. (*Mr. Michael.*) What is the death-rate from zymotic diseases?—There is a figure for each place.

11,831. (*Mr. Balfour Browne.*) The table will be handed in to-morrow when the rest of the tables are handed in, but if my learned friend wants any particular figure he can have it?—Tables 7 and 8 have been already printed, and those are very important.

11,832. Taking the deaths from the several zymotic diseases in the districts upon the north side of the Thames, does it appear from the table you have before you that those deaths from measles, scarlet fever, and diarrhœa, are in almost all instances very largely in excess of those in the eastern registration division?—Yes, those deaths from measles, scarlet fever, and diarrhœa, are all very much in excess.

11,833. Would you give the figures of the deaths from measles in the eastern registration division?—The deaths from measles in the eastern registration division are 0·17 per 1,000 persons living. Now, in Aldgate the proportion is 0·46; St. Paul, 0·73; Stepney, 0·74; Poplar, 0·68; West Ham, 0·40; Barking Town, 0·26. In Hornchurch, which is the district I have been describing as chiefly consisting of small villages, there the death rate from measles is 0·24, and in Orsett it is 0·29.

11,834. (*Chairman.*) Barking Town is the most healthy place going apparently?—It depends upon which disease you take; the death rate is less in measles than in other places, but if you take scarlet fever you find a very different result. In scarlet fever the eastern registration division is 0·40; London generally is 0·60; Aldgate is 0·66; St. Paul, 0·58;

*Prof. W. H. Corfield, M.D.*

13 March 1883.

Stepney, 0·82; Poplar, 0·85; West Ham, 0·75; Barking Town, 0·90; Hornchurch, 0·33; Orsett, 0·55.

11,835. (*Prof. Williamson.*) Do the riparian districts average more than London?—Yes.

(*Mr. Michael.*) The two distinguishing points in zymotic diseases, namely, fever and diarrhœa, are lower at Barking than any other places upon the table.

11,836. (*Mr. Balfour Browne.*) Take diarrhœa, the next column but three, and give the figures?—The eastern registration division gives 0·72 and London 0·92. Of these districts Aldgate is 1·27; St. Paul, 1·12; Stepney, 1·22; Poplar, 1·06; West Ham, 1·02, as against 0·72 for the eastern registration division.

11,837. Which is the next column you will take?—Fever.

11,838. What does fever include?—Fever includes enteric fever, typhus, and simple continued fever; but it is chiefly enteric fever, of course.

11,839. What results do they give?—In fever the eastern registration division gives 0·35. I did not mention fever, you will remember, as being excessively prevalent in those districts. Aldgate is 0·40; St. Paul, 0·37; Stepney, 0·35; Poplar, 0·37; West Ham, 0·30; Barking Town, 0·29; Hornchurch, 0·32; Orsett, the highest of the lot, gives 0·56, and London, 0·37.

11,840. As far as fever is concerned, following the figures you have just given, it seems to me that the districts and the registration division are very much upon a par?—Yes.

11,841. But in relation to diarrhœa, scarlet fever, and measles, the riparian parts of the parish are very much in excess?—Yes, and that is especially true of scarlet fever.

11,842. Is there anything in the nature of the population living along the banks of the river that would account for it to your mind?—I do not know of anything specially to account for it.

11,843. (*Chairman.*) What do you attribute it to?—I cannot tell you all the causes of it. I have very little doubt that one of the causes is the condition of the river, that is to say, one cause of the increased general zymotic death rate along its banks upon both sides, and of the special increase in certain zymotic diseases, most notably scarlet fever.

11,844. (*Prof. Williamson.*) You first said it was owing to the condition of the river. Now we want to know what there is in the sewage which causes the river to act in a different way from what it would without the sewage. This river, no doubt, produces fogs, and that may conduce to the enjoyment of a different state of health, but is there anything inherent in the condition of the river itself which leads to a different condition of health being enjoyed by those living on its banks?—I have no doubt the foul condition of the river has an effect upon the population living upon the banks.

11,845. Do those statistics lead you to say that the river with the sewage is anything worse than a river without the sewage?—It leads me to the conclusion that the high zymotic death rate is partly due to the sewage flowing down the river.

11,846. (*Mr. Balfour Browne.*) Is it your opinion then that if it were nothing but pure water flowing down the stream the death rate would be lessened?—I have no doubt that it would be lessened.

11,847. (*Dr. Stevenson.*) Have you compared the influence of living here with the influence of living upon the river higher up?—No, have not. I have compared it with the effect of living lower down.

11,848. (*Mr. Balfour Browne.*) Your tables will show that. You have dealt hitherto with the northern side of the Thames. Now, will you go to the south. Do you find the same result there—that the general zymotic death rate is increased by proximity to the river?—Yes, it is higher in all the districts upon the south than it is in the general south-eastern division.

11,849. (*Sir John Coode.*) How does the district east of the Medway compare with that to the west of it?—Upon the north side east of the Medway the zymotic death rate is a little below the death rate of the eastern registration division. The north side includes the two large towns of Southend and Rayleigh, and the death rate is rather less than in the whole eastern registration division. Upon the south side the zymotic death rate of Sheppey is decidedly less, and the zymotic death rate of Blean, which is a little further on, is a little less than that of the south-eastern registration division generally.

11,850. Is not that to be expected as we are getting on to the sea-board where you get more of the pure sea breezes?—No doubt.

11,851. (*Mr. Balfour Browne.*) As a fact, you find that in the Isle of Sheppey the death-rate is lower than in the whole of the south-eastern registration division?—Yes, it is.

11,852. (*Sir John Coode.*) And there you get on to the chalk, which is also healthier?—It is undoubtedly healthier there.

11,853. (*Mr. Balfour Browne.*) Now, taking the south side in the same way as you did the northern side, would you trace what is the indication down that bank, of measles, scarlet fever, and diarrhœa?—In measles the death rate of those districts is higher than that of the south-eastern registration division, with the exception of Gravesend, where it is a little lower.

11,854. Otherwise is it much higher?—It is decidedly higher.

11,855. Can you do the same there as you did upon the north?—I can say that on the south, in respect to these three diseases, the death rate in each of these districts I have taken is higher: there may be one exception, namely, Gravesend, in the case of measles, otherwise the death-rate is almost in every instance higher than the corresponding death rate for the south-eastern registration division. As regards fever, however, I must except Hoo, for this reason, that the people there seem to die of nothing but fever; everything seems to be put down to fever in Hoo. There is scarcely any scarlet fever, and scarcely any measles there, but the death-rate from "fever" is enormous; so that it is perfectly clear that they put down everything that is of a feverish nature as "fever." When you look at the table you will see that the sub-district of Hoo has a death rate from "fever" not far off three times that of London.

11,856. But that is to be accounted for by the fact that they have no death rate in anything else?—I would say that that district must not be considered except as regards the general zymotic death rate.

11,857. Now, leaving that out, does it prove that deaths from zymotic diseases in the riparian parts of this district on the south side are very much greater than in the south-eastern registration district?—Yes, it does.

11,858. Upon the north side does the mortality exceed that in London generally?—I have only the zymotic diseases in these tables.

11,859. Taking them altogether, does the rate of mortality from all diseases north of the Thames exceed the average for London?—It does from zymotic diseases.

11,860. Upon the south side is the same the case, is there an excess of the zymotic death rate there over the whole of London?—Not over the whole of London, with the exception of St. Olave's, Southwark.

11,861. In the other cases the zymotic death rate exceeds that of the districts of which they form a part?—Yes. There is one sub-district, that of Bexley, where, I believe, the actual majority of the population is in places at a considerable distance from the river, and while the zymotic death rate there is about equal to the death rate of the south-eastern division, generally, the death rate from scarlet fever is very much higher than it is in that division, and very nearly approaches that of London.

11,862. Now what does Table 9 show?—Table 9 shows the density of the population in each of those

districts on each side of the Thames in 1871 and in 1881; it shows the area in acres in each district or sub-district; the population in 1871 and in 1881, and the population per acre in 1871 and in 1881, and then it shows the corresponding figures for London and for the eastern registration division.

11,863. Upon Table 9 have you the density of the population in Orsett?—Yes.

11,864 Is the density of population there the same as that of the eastern division generally?—It is almost exactly the same; it is slightly less.

11,865. Can you tell the Commission whether the death rate from zymotic diseases is about the same?—It is decidedly greater than in the eastern registration division.

11,866. Now by Table 10 you give the density of the population upon the south side?—Yes.

11,867. Would you look at the district of Northfleet?—Yes, I will.

11,868. Is the density of population in the district of Northfleet the same as for the south-eastern registration division?—Yes, almost exactly. *Prof. W. H. Corfield, M.D.*

11,869. Is the death rate from zymotic diseases, such as scarlet fever and fever, higher in Northfleet than in the south-eastern registration division?—Yes, it is, very considerably, in Northfleet it is higher than in any other place below Greenwich. 13 March 1883.

11,870. Northfleet is just above Gravesend is it not?—Yes, Northfleet is just above Gravesend.

11,871. There might be accidental irregularities upon these tables, how have you eliminated those?—By taking the statistics separately for 10 years for each year and averaging them.

11,872. You think that is sufficient to eliminate any possible irregularities that might vitiate the smaller induction?—Yes.

(*Mr. Lumley Smith.*) As I understand, my learned friend wishes to have the person produced who took the samples for determining the amount of chlorine at Southend.

(*Mr. Michael.*) At Gravesend and Southend.

Adjourned to to-morrow at 12.30.

---

# THIRTIETH DAY.

## Wednesday, 14th March 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR P. BENSON MAXWELL.
SIR JOHN COODE, Mem. Inst. C.E.
PROFESSOR WILLIAMSON, F.R.S.

FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, Esq., F.R.S., *Secretary.*

Professor W. H. CORFIELD called again and further examined.

11,873. (*Mr. Balfour Browne.*) Have you the tables which you promised to hand in to the Commission yesterday?—I have. (*See Evidence of previous day.*) 14 March 1883.

11,874. I think when we left off you were going to give a description of Table 11; will you now proceed to do so?—Table 11 refers to a place called Dagenham, which is part of the division of Romford, which is itself part of the sub-district of Romford. This is given in a separate table, because I was not able to get it from the Registrar General's returns direct, but had to go to the returns sent in by the local registrars. I have taken out from them the death-rates, and the number of deaths during the 11 years from 1871 to 1881, from each zymotic disease, and the total number, and from them I have calculated the average annual number for the 10 years from 1871 to 1880, and the average annual death-rate for the 10 years from 1871 to 1880, as I did with regard to the previous districts. I find that the zymotic death-rate in that small district is 3 per 1,000 per annum, as against 2·38 in the eastern registration division generally, of which this forms a part.

11,875. The situation of Dagenham is just below Barking Creek, is it not?—It is a little way below Barking Creek; it is part of the district that is included in Romford.

11,876. (*Chairman.*) Is the general death-rate greater there than in the other place you have compared it with?—I am afraid I have not the general death-rate for Dagenham.

11,877. (*Mr. Balfour Browne.*) The witness is only taking the death-rate from zymotic diseases; he is comparing the death-rate from zymotic diseases in districts down the river with the death-rate in the districts away from the river; is that so?—Yes, the general death-rate is to be found in Tables 1 and 2, but I cannot answer as to the general death-rate with regard to Dagenham. I should like to add that, with regard to the district of Dagenham, I was not able to get the deaths from the Registrar General's returns, else I should no doubt have given that, but I had to go to the original returns sent in by the registrar of the place to get them, and I have only worked out the deaths from zymotic diseases, which is what I was inquiring into.

11,878. Have you made a comparison with the districts immediately below those included in the tables you have put in?—Yes.

11,879. Those are on the north side, part of the Rochford sub-district.

11,880. (*Chairman.*) Are the conditions of the districts compared the same, or are the districts that you have compared the river-side districts with upon a hill or what not?—The comparison is this: there are certain districts upon the north bank of the Thames between London Bridge and opposite the Medway. These sub-districts form part of the eastern registration division, which includes the counties of Essex, Suffolk, and Norfolk. I have compared the zymotic death-rates in the districts bordering upon the north side of the Thames with the zymotic death-rates of the general districts of the eastern registration division of which they form a part.

11,881. You are comparing, as I understand, the zymotic disease-rate in low lands, with the zymotic disease-rate in lands that are both high and low?—Yes, that is necessarily so.

11,882. That seems to me to take away a great part of the value of it, unless you can say that the

*Prof. W. H. Corfield.*

14 March 1883.

populations on the low lands have no greater tendency to zymotic diseases than those upon the high lands?—Then I go on to compare the death-rate in the districts near the Thames with those in the districts lower down the Thames.

11,883. (*Mr. Balfour Browne.*) You have compared, have you not, the death-rates of the places higher up the Thames with the death-rate of the districts of Rochford on the north side, and the island of Sheppey and Blean on the south side?—Yes.

(*Mr. Bidder.*) Those are salt water districts.

(*Witness.*) Table 12 shows the annual number of deaths from zymotic diseases, and the annual death-rate in the districts of Rochford, Table 13 and those for Sheppey, and Blean.

11,884. (*Mr. Balfour Browne.*) Where is the sub-district of Rochford?—It is upon the north side of the Thames, and includes the places of Southend, Rayleigh, and Prittlewell.

11,885. What places do you take on the south?—Sheppey and Blean.

11,886. What does the table show with regard to zymotic diseases in Rochford?—Table 12 shows that the average death-rate from zymotic diseases in Rochford for the 10 years is, practically speaking, the same as that for the eastern registration district generally.

11,887. Which includes the three counties you have mentioned?—Yes, it includes the three counties which I have mentioned, with their towns.

11,888. Therefore in Rochford the death-rate from those diseases is lower than in the riparian sub-districts higher up the river?—Yes, it is.

11,889. (*Chairman.*) Rochford is in a very low situation, is it not?—Yes. Then I should add that in that district of Rochford the scarlet fever death-rate is less than in the eastern registration division, and very much less than in any of the districts up the Thames.

11,890. (*Mr. Balfour Browne.*) Scarlet fever is a disease to which you have specially drawn attention in these tables?—Yes, it is the disease which is shown to be specially prevalent in those districts near to the banks of the Thames above the Medway.

11,891. (*Chairman.*) Some part of the eastern registration division is the most healthy district in England. I should think the chalk lands of Norfolk are very dry though not very high; and there is no part of England more healthy, is there?—I have no doubt that they are very healthy, but I have not gone into the case of those parts.

11,892. (*Mr. Balfour Browne.*) In the eastern registration division there are a very considerable number of large towns, are there not?—Yes.

11,893. Of course the condition of those has a good deal to do with the spread of zymotic diseases?—No doubt.

(*Chairman.*) What struck me about Rochford being so healthy was that it appeared to prove too much.

11,894. (*Mr. Balfour Browne.*) These healthy places that you have been referring to in the eastern district bring down the death-rate as against the large towns?—They do.

(*Mr. Bidder.*) The death-rate in the eastern district is very low.

11,895. (*Dr. Stevenson.*) I would ask you whether the defective registration of which you spoke would have anything to do with the result shown by these figures, that is to say, the registration of a case of scarlet fever as a simple case of fever; have you been able to trace that practice in any other place?—I have not noticed that to any extent. Of course there is the possibility that in Rochford some cases of scarlet fever may be registered as measles. If you take scarlet fever and measles together you get in the eastern registration division generally ·57, and if you take Rochford you get ·44.

11,896. (*Chairman.*) Have you any comparison between your other places and such a place as Grays or Purfleet, where it is not marsh land, but chalk at some elevation?—Grays and Purfleet come into some of those divisions which I have got, but I have not been able to take them separately.

11,897. (*Mr. Balfour Browne.*) Of course Grays and Purfleet are in some of your divisions; will you just find out what division they are in, and give the death-rate?—Grays comes in under Orsett, and the zymotic death-rate of Orsett, taking it altogether, is certainly higher than it is in the eastern registration division.

11,898. (*Chairman.*) You are giving the district in which Grays is?—Yes; I am not able to give Grays separately.

11,899. (*Chairman.*) How is Sheppey divided?—Sheppey is divided into Minster and Eastchurch.

11,900. Minster is pretty high ground, is it not?—Yes, but I have not been able to separate the figures.

11,901. (*Mr. Balfour Browne.*) I want you to do the same upon the south side of the river as you have done upon the north, that is to say, compare the river-side places with that which is at the mouth of the river, namely, Sheppey and Blean?—The zymotic death-rate in Sheppey during the 10 years has averaged 1·9 as against 2·38 in the south-eastern registration district generally; that is to say, the zymotic death-rate of Sheppey is less than in the south-eastern registration division generally.

(*Chairman.*) Has it ever been suggested that the influence of the sewage has been felt in Sheppey?

(*Mr. Balfour Browne.*) No; the witness would say that the influence of the sewage has died out before reaching Sheppey, and that, therefore, the death-rate has gone down.

(*Chairman.*) Then, in fact, you might take Newcastle-upon-Tyne or any other place to compare with.

(*Witness.*) I show that the death-rate in Sheppey is less than in the south-eastern district generally.

11,902. (*Mr. Balfour Browne.*) And the same, of course, with regard to Blean?—Yes, the same with regard to Blean.

11,903. Would you compare those two with regard to the death-rate in scarlet fever?—In scarlet fever they are both less than in the south-eastern registration division generally, and decidedly less than in any of the districts upon the south side of the Thames, which I have already spoken of, with the exception of Hoo, which I mentioned yesterday.

11,904. (*Chairman.*) Where is Blean?—It is a district beyond Sheppey; it includes Herne and Whitstable.

11,905. (*Mr. Balfour Browne.*) With regard to scarlet fever, you say that until you come down to Sheppey and Blean the death-rate from scarlet fever is higher than in the division of which those places form a part?—Yes.

11,906. With the exception of Hoo, where they register everything as fever?—Yes.

11,907. Something was said yesterday about the character of the soil of Sheppey and Blean. I think Sir John Coode suggested that it was chalk, and that, therefore, that might account for the health of those districts?

(*Mr. Abernethy.*) The soil of Sheppey is not chalk.

(*Chairman.*) A part of Sheppey is comparatively high land, with cliffs to the sea, in which pyrites are found.

(*Mr. Balfour Browne.*) It was suggested yesterday that chalk was the soil; what do you say is the soil?

(*Witness.*) It is practically all tertiary clays or post-tertiary alluvial deposits in all those districts; you do not get to the chalk, in fact, until you come to Canterbury.

11,908. I think, roughly, in all these tables you lay special stress upon scarlet fever as an indication of the health upon the banks of the Thames?—Yes, that is what the tables show especially.

11,909. Is there anything that you wish to add in explanation of any of those tables?—I do not think so.

Cross-examined by Mr. BIDDER.

*Prof. W. H. Corfield.*

14 March 1883.

11,910. I suppose there is no doubt about the truth of one statement or the accuracy of one observation you referred to this morning, that density of population has a great deal to do with the deaths from zymotic diseases?—Yes, no doubt it has.

11,911. Apart from any other element?—No doubt it has.

11,912. Consequently, taking any district in London, you expect to find a higher death-rate from zymotic disease than if you take districts in the country?—No doubt you would expect to find that the case.

11,913. (*Sir P. Benson Maxwell.*) But when you say you expect to find it, have you any experience that you do find it; is it the result of observation?—I can, no doubt, pick out a part of London where the zymotic death rate is less than in several of those districts where the density of population is less than in London.

11,914. Taking two districts of different density of population, would you expect to find more zymotic disease in the more densely populated district?—You would.

11,915. Is that the result of your experience and observation, or is it a theory of your own?—It is the result of experience, but still it is dependent upon circumstances. I can give you a number of cases of less zymotic disease with a denser population.

11,916. (*Chairman.*) Is that a recognised principle in medical science?—Yes.

11,917. (*Mr. Bidder.*) Experience, not only in London but throughout England shows, does it not, that as the density of population increases so, *cæteris paribus*, the death-rate from zymotic diseases rises?—Yes, but I can give you exceptions.

11,918. Now I will put to you another general proposition, and I will ask you whether this is not applicable to London and other towns where the population is more or less dense, that in the parts of the towns where the poorer classes are more or less collected together you find the zymotic death-rate higher than in the parts of the towns where the better and higher classes principally reside?—That is so, no doubt.

11,919. Applying that to London, that would be saying, in other words, that the East London zymotic death-rate is higher than the West London zymotic death-rate?—It is higher as a rule.

11,920. Quite apart from density of population?—Quite apart from density of population.

11,921. So that the average zymotic death-rate of the whole of London being, as you give it in Table 7, 3·84, without any reference to any influence of the Thames, you naturally expect the zymotic death-rate of East London to be something above 3·84, and that of West London to be below it?—Supposing the population of Eastern London to be the denser.

11,922. Not supposing anything; taking Eastern London as it is?—Assuming the population in Eastern London is denser, I should expect it.

11,923. Do not assume anything. As a matter of fact, the population is denser in Eastern than in Western London?—That is so.

11,924. Besides its being denser, as a matter of fact, it is a much poorer population in Eastern than in Western London?—No doubt it is.

11,925. Those two causes both operate to raise the death-rate from zymotic diseases in Eastern London above the average?—Yes.

11,926. That applies to all Eastern London, whether riverine or not?—Yes, it does, no doubt.

11,927. (*Sir P. Benson Maxwell.*) Do you know anything about the comparative density of the eastern population of London and the western population of London?—I cannot give you the figures; I can only speak as it in general terms.

11,928. (*Mr. Bidder.*) You have given in your Table 9 the density of population per acre?—That is in Tables 9 and 10.

11,929. The one for the population on the north and the other for the south side of London, but, unfortunately, you only give it for the districts you have selected, which are all districts of East London. Can you, by reference to the Registrar General's returns, give the figures for Western London?—At any rate, the figures given in my table show that the density of population in the first four districts upon the north side of the Thames is greater than it is in London generally, and considerably greater than in some of the others.

I am much obliged to you. You show that several of these districts, the first four, are far above the London average.

(*Chairman.*) I might tell you that Mr. Heywood has been kind enough to tell us, that he, on a former occasion, calculated the density of population, and found it was greatest in the sub-district of St. Anne's, Soho, and one of the Holborn sub-districts. I think that likely, because the houses are larger there, and, if it is a poor population, the streets being narrow, you have more people living upon the same piece of ground.

11,930–31. (*Mr. Bidder.*) That would be so; but, dealing with the particular districts dealt with by the witness by Table 9, Dr. Corfield shows that upon the north side of the river the four first districts have a population denser considerably than the average of London. London is given at the bottom of the table as 50 to the acre. (*To the witness.*) Now, if you turn back to Table 7, those are the very four districts in which you show a zymotic death-rate above the average zymotic death-rate of London?—Yes, it is above the average of London.

11,932. Of the other districts you have selected, West Ham, Barking, Hornchurch, and Orsett, the last two are mere country places; but, taking Barking and West Ham, they have a density below, and considerably below the average of London, and when we turn back to Table 7, we find that the zymotic death-rate is slightly below the average of the zymotic death-rate of London?—That is so.

11,933. Now, will you take the south side of the river, Table No. 10?—I was going to say that, if you keep to London, the zymotic death-rate of Barking and West Ham is very little below the death-rate of London, whereas their density is enormously less.

11,934. But you do not suggest that even when you get into the pure country you eliminate zymotic disease; your own tables show that you have it in the most healthy districts. Now, Table 10 gives us the same things for the south side, and that shows that only one district you have selected, namely, St. Olave's, Southwark, is above the average density of London as regards population?—Yes.

11,935. Then, turning to Table 8, that is the only district whose zymotic death-rate is above the average for London?—It is above the average for London; but the fair thing to compare these with is not the death-rate of London, but the death-rate of the registration divisions to which they belong.

11,936. Take St. Olave's, Southwark; what do you say it would be fair to compare that with?—It would be fair to compare that with London.

11,937. Take Greenwich?—The population of Greenwich is 38·3 to the acre; it is fair to compare that either with London or with the general registration district.

11,938. Is that the registration division which is at the foot of that table?—That is the registration division.

11,939. The population of which, instead of being 38 people to the acre, as in Greenwich, is half a person to the acre; would that be fair?—The population in Greenwich is only two-thirds of the proportion in London; in London it is 50·6.

11,940. Surely you know that the population of Greenwich is essentially an urban population?—Yes, it is.

11,941. What brings down Greenwich really to

*Prof. W. H. Corfield.*

14 March 1883.

below the average of London is the fact that Greenwich Park is within it, and helps the acreage, is it not?—Yes.

11,942. And nobody but the Astronomer Royal and his assistants lives in Greenwich Park?—That is so.

11,943. There is also Blackheath in it?—Yes, there is.

11,944. Now, Tables 12 and 13 refer, for places of comparison, to Rochford, including Rayleigh and Prittlewell; to Sheppey, including Minster and Eastchurch; and to Blean, including Herne and Whitstable; are not those essentially seaside places?—They are estuarian; they are in the estuary, no doubt.

11,945. Herne Bay is a place to which people go for bathing, is it not?—It is.

11,946. And Whitstable is a place sufficiently marine for oysters, at all events?—Yes, it is so.

11,947. And, as the tables show us, the density of the population is remarkably thin. Blean has only half a person to the acre, Rayleigh and Prittlewell only one third, and Minster and Eastchurch ·8 of a person?—That is so, but they are about a fair average of the registration division generally, so it is fair to compare their death-rates together.

11,948. Now, turning back to Tables 7 and 8, the selected districts, is it not the case that many of those districts which you have selected, although they are riverine in the sense that in one part of their boundary they touch the river, run very far back from the river, and a very small proportion of their population is contiguous to the river?—Not a very small proportion. There are, it is true, some of those districts in which most of the population is away from the river; but, in most of those that I have selected, the population is near the river, at any rate.

11,949. Have you any map which will show the boundaries of the districts?—I have a map upon which the districts have been roughly marked. (*The same was handed to the learned counsel.*)

11,950. Which of your districts does Limehouse fall within?—Stepney.

11,951. Have you taken the City of London?—No.

11,952. That is a riverine district, is it not?—I begin at London Bridge. Aldgate is the first below London Bridge, Aldgate being part of Whitechapel.

11,953. I see Stepney runs back a mile or more from the river, does it not?—I dare say it does run back a mile or more from the river.

11,954. How far do you suggest that the influence of the River Thames, if it has a deleterious influence, could possibly be conceived to extend?—I cannot tell. I am told that sewage can be smelt three miles from the river. I have never smelt it three miles from the river.

11,955. Do you believe it?—I do not know whether to believe it or not.

(*Chairman.*) Barking Town is more than a mile from the river, is it not?

(*Mr. Bidder.*) It is about two miles from the river.

(*Chairman.*) You see the death-rate from zymotic diseases in Barking Town is 3·12.

(*Mr. Bidder.*) As against 3·84 for London generally.

(*Witness.*) And as against 2·38 for the eastern registration division.

(*Sir P. Benson Maxwell.*) Barking Town is full of cesspits, I believe, and that might account for that proportion of zymotic disease.

(*Witness.*) I ought to say that Barking Town means the district; it does not merely mean the town; it means the district which comes down to the river.

11,956. (*Mr. Bidder.*) I will go regularly along. I have asked you about Stepney. Now, the Poplar district goes back as much as three miles from the river, that is to say, what you have embraced as the Poplar district?—I can only tell by referring; but when you say "what I have embraced," I have only embraced what I was bound to do by the returns of the Registrar-General. The farthest point of Poplar to the nearest point of the river is about 2½ miles; if you take it from the farthest point of Poplar to the farthest point of the river you may make four miles of it.

11,957. How far does West Ham stretch back from the river, taking the farthest part of it?—The farthest point of West Ham from the river is three miles.

11,958. Now with regard to Barking Town district, how far does that go back from the river?—2½ miles at the outside; it is hardly as much as that.

11,959. By-the-bye, passing back for a moment to the West Ham district, if I remember rightly, the population there lies away from the river, and the immediate banks of the river have a comparatively sparse population, because it is occupied principally by docks, and open land opposite Woolwich?—That is so, the population is mostly away from the river.

11,960. Now I go to the next, the Barking district embraces the actual outfall itself, does it not?—That is not marked upon my map.

11,961. Is it not the case that your Barking district actually embraces the northern outfall?—No, I think not. I think the northern outfall is in the West Ham district, but it is not marked upon my map.

11,962. You are quite right, the outfall is just at the boundary, between Barking and West Ham, and above the Barking district. Now, I suppose, if the sewage has any deleterious effect upon health, you would expect that it would be strongest in the immediate neighbourhood of the sewage outfalls?—I do not know that, but if the whole state of the river is in a bad condition—

11,963. If it is bad, it would be worse near the outfalls?—At times it would be worse near the outfalls, no doubt.

11,964. I see your returns show Barking to have, as compared with the other places, a remarkably low average of zymotic disease?—You will see also that it has an enormously high death-rate from scarlet fever, higher than the east of London, and the other places.

11,965. Of course that includes Barking Town; are you aware of the condition of Barking Town itself, as to its sewage?—I know something about it.

11,966. Do you know that Mr. Rawlinson held an inquiry under the Local Government Board, and made a report upon the case some years ago, in 1869, it was called an inquiry as to the truth, or otherwise, of certain allegations which were contained in a memorial from the vicar, and other inhabitants of Barking, in the county of Essex, calling attention to the pollution of the River Thames, by the discharge from the northern outfall sewer of the Metropolitan Board of Works, now just let me draw your attention to one sentence.

(*Chairman.*) Perhaps Mr. Bidder would ask whether that did not differentiate the case of Barking, so that you cannot take it as a criterion.

(*Mr. Bidder.*) Mr. Rawlinson says as one of the "conclusions" of his report, "that the memorialists "are not in a position to establish deterioration of "health to emanations from the metropolitan main "sewerage outfall works, as the town of Barking is "without local governing powers, is unsewered, "contains many cesspools, a sewage tainted subsoil, "and has a defective water supply."

11,966*a*. (*Sir P. Benson Maxwell.*) Do you know whether that is true or not?—I do not know.

11,967. (*Chairman.*) I think we may take it for granted that we do know, this being so authoritative a statement that I think the Commission would act upon it. Then I suppose the question is, supposing that to be true, does not that preclude Barking from being used as a criterion, one way or the other?—To a certain extent it does, but what I show is that the death-rate from zymotic diseases, especially from scarlet fever, is excessively high along both banks of the Thames.

11,968. Mr. Bidder will get rid of it, no doubt, bit by bit, as soon as he can, but that, I think, he will contend will get rid of Barking?—Except that the

learned counsel was not here yesterday, when I introduced this subject.

(*Mr. Balfour-Browne.*) Only it must be remembered that that paper refered to 1869, and the tables refer to the period from 1870 to 1880.

11,969. (*Mr. Bidder to the witness.*) Now I will ask you a question about the corresponding Table 8, which relates to the south side; do you include Bermondsey, and if so, in which of your divisions do you include Bermondsey?—St. James', Bermondsey, that is to say, part of Bermondsey, is included.

11,970. Why did you not take the whole of Bermondsey?—I took St. Olave's Southwark, St John, Horseleydown, and St. James', Bermondsey, and Rotherhithe, they are all riparian.

11,971. (*Chairman.*) Is Deptford in either of the districts?—Yes, that is in Greenwich.

11,972. (*Mr. Bidder.*) Now your next district is Greenwich?—Yes.

11,973. Is it not the fact that in certain of these districts of the Registrar-General's, and the observation applies, I think with particular force, to Greenwich, and another that is mentioned, deaths are included which occurred at hospitals situated in those districts where patients are taken in, who contract their illness in other districts?—That is the case, no doubt, in some of the districts. I dare say it is in Greenwich, but I do not know that.

11,974. Do not you know, for instance, that in Greeenwich the death-rate from zymotic diseases is largely affected by the presence of patients in the hospital, brought from other places?

(*Chairman.*) Which hospitals do you refer to?

11,975. (*Mr. Bidder to the witness.*) To begin with, are you not aware that there was a small-pox hospital which accommodated the population of a great part of London, and which was only removed, I think, about 18 months ago, lower down the river into the sewage section, as being a healthier spot. Now are you aware that the death-rate of the floating hospital has been included in the zymotic death-rate?—I have no doubt that it has.

11,976. Have you eliminated those deaths?—No, I have not.

11,977. (*Chairman.*) Do you suggest that the influence of the sewage is sensibly felt as high as Rotherhithe, Bermondsey, and that neighbourhood?—I do not suggest, with regard to the figures at the beginning of the scale, as high up in the river as that, that the influence of the sewage has anything to do with those figures.

11,978. But in the St. Olave district the death-rate from zymotic disease is higher than anywhere else on your table?—But there the population is denser.

11,979. And you have Guy's Hospital; I do not know whether that makes a difference?—Yes, that would be in it. I began at London Bridge, for the sake of some place to begin at, but I do not suggest that I can show that the sewage has any influence as high up as that.

11,980. If the population is denser there, it would rather go to show that places lower down and more within the influence of the sewage, are better off than they are in Southwark?—So they are better off, because the population is denser in Southwark.

11,981. (*Mr. Bidder.*) I suppose your figures are taken from the returns of the Registrar-General?—They are taken from the quarterly returns, not from the annual summaries.

11,982. In Poplar also, I think there is a hospital which accommodates a very large district, is there not?—I do not know as a matter of fact that there is; I do not remember that.

11,983. (*Chairman.*) The London Hospital, in the Whitechapel Road, is not in Poplar, I suppose?—I do not know.

11,984. (*Mr. Bidder.*) Now I will read you a passage from the Registrar-General's Return for 1881. "In the southern group, which is the second highest "rate, there are two small-pox hospitals, and the "districts which would be specially affected by their "presence, would be Greenwich, Camberwell, and "Lambeth." Now here, you see, the Registrar-General himself, is of opinion, that the Greenwich death-rate is very much affected by the presence of the small-pox hospital?—It is, no doubt; my tables show that it is.

11,985. But you tell me you have not eliminated from the Greenwich death-rate, those deaths that are due to the hospital patients brought from other districts?—That is so. I have not been able to do so for any of those districts.

11,986. (*Professor Williamson.*) Are there hospitals for zymotic diseases in several parts of London?—There are in several districts.

11,987. Are they specially about the river?—They are not.

11,988. But are not patients who are or may be afflicted by zymotic diseases admitted to general hospitals?—Yes; with certain zymotic diseases, enteric fever, and diptheria, and in certain hospitals, (one or two) with scarlet fever; but cases of enteric fever and diptheria are admitted to any of the general hospitals.

11,989. Are there special hospitals to which scarlet fever patients are admitted?—There are special hospitals to which scarlet fever patients are admitted.

11,990. Where are they located?—There is the Fever Hospital at Homerton, and another at Stockwell.

11,991. (*Dr. Stevenson.*) The small-pox hospital is now at Deptford?—It is. You see the death-rates from small-pox are higher in Greenwich and Dartford in these tables, than they are anywhere else on the south side, and at Greenwich the death-rate is higher than the general death-rate in London.

11,992. (*Mr. Bidder.*) There was a small-pox hospital at Homerton, was there not?—There was, I believe.

11,993. Do you know whether it was not the fact that the patients at the small-pox floating hospital, moored at Greenwich, were found to be healthier and to do better than those in the hospital at Homerton, and at other places on land?—I do not know that.

11,994. Now I will ask you a general question; is it not the case that following shortly, or within a year or two after the completion of the main outfall drainage system and the pouring of the sewage into the river at Barking and Crossness, there was a most marked and permanent improvement in the death-rate of London?—I am not aware of that at the moment.

(*Chairman.*) But permit me to put it to you, Mr. Bidder, in this way; if you poured it out about 5 or 6 miles away, at the edge of the London population, instead of pouring it out all amongst them here, would that not account for the falling off in the zymotic disease rate, supposing that sewage had anything to do with it; it would rather tell against you than anything, I should have thought, but you have the right to ask the question in the interests of truth, no doubt.

(*Mr. Bidder.*) From my learned friend's view, yes, but from mine, no, my lord. However, I will not follow that up.

11,995. (*Sir P. Benson Maxwell.*) Do you know whether the rate of zymotic disease in the upper part of the metropolis has fallen since the sewage has been carried down below?—I believe it has.

11,996. *Mr. Bidder.*) You know, I daresay, that the Registrar-General gives the deaths from zymotic diseases per 1,000 of the population for every year for many years past?—Yes.

11,997. Will you just look at that table (*handing a copy of the Registrar-General's Return to the witness*). I think that shows, upon the face of it, that to about the year 1870 or 1871, the number of deaths ranged between 5 and 6, and from that time downwards they have ranged somewhere between 3 and 4 per 1,000; in point of fact, they are not very much more than half what they were before?—Yes; it is true that down to the year 1871 they range from 3½ upwards.

(*Chairman to Mr. Bidder.*) But need you trouble

*Prof W. H. Corfield.*

14 March 1883.

Dr. Corfield with this, because I do not understand that you are going to ask him a question upon it; you might put the book before us when you come to address us.

11,998. (*Mr. Bidder.*) I will do it in that way. (*To the witness*), I have asked you about Greenwich. Now the Woolwich district, the next you take, runs back, I think, about three miles from the river?—The farthest part is about three miles from the river.

11,999. That is the Bexley district?—But most of the population in the Woolwich district is within a mile of the river.

12,000. The Bexley district, which you have taken, runs back about five miles?—It does.

12,001. How many miles does the Dartford district go back?—The farthest point would be about five miles from the river.

12,002. Northfleet goes back about nine miles from the river, and you show that as about the highest of them all?—I have included what is in the district. I have not been able to divide the district.

12,003. How far back do you say the district goes?—The farthest point would be about 7½ miles from the river.

Re-examined by Mr. Balfour Browne.

12,004. Just let me understand; you have included in these districts, nothing but what is included in the sub-district of the Registrar-General?—No, or in parts of the sub-district which I have been able to take.

12,005. Perhaps the better plan would be to draw a line from the river to a certain distance off, where you supposed the influence of the river would terminate, and find out what the death-rate in that was?—It would, no doubt, but that would have been impracticable.

12,006. Now taking Greenwich, which is the highest one of all, I think the death-rate from zymotic diseases was lower than in the other districts, that is to say, if you deduct the smallpox?—It is on the second sheet of Table No. 2.

12,007. Deducting the 49 which represents the smallpox?—

12,008. (*Chairman.*) Hoo is certainly out of the reach or influence of the sewage, is it not?—I should think it is. Hoo is below Gravesend.

12,009. Its population is very nearly the lowest of all that you have; it is ·17 to the acre?—Yes.

12,010. I think there is no other so low as that?—I think that is the lowest.

12,011. And yet the death-rate from zymotic diseases is 2·63, that is above the average; no doubt it is not so great at St. Olaves, Southwark, nor so great as Greenwich, but greater than Bexley, and nearly as great as Dartford, and nearly as great as Gravesend?—The reason of that is the high death-rate in the sub-district from diarrhœa.

(*Mr. Bidder.*) And fever.

12,012. (*Chairman.*) What causes the diarrhœa?—Diarrhœa is chiefly caused by drinking impure water. I do not attach much importance to the death-rate in this particular case; "fever" includes everything else; if that which is put down is the death-rate from scarlet fever, then Hoo is abnormally low.

12,013. (*Mr. Bidder.*) But the death-rate from "fever" is higher than anything else?—That is because the medical attendant puts down everything he does not know as "fever," there is no other way of accounting for the death-rate from "fever" but that.

12,014. (*Mr. Balfour Browne.*) My learned friend read you an extract from the Registrar-General's Report to show that the death-rate in Greenwich, Camberwell and Lambeth, was attributable to smallpox hospitals?—Yes.

12,015. And Greenwich appears in London?—Yes.

12,016. And all the other London Districts you have given go to swell the death-rate of London?—Yes.

12,017. Now taking the districts upon the south side, the density of population is very much smaller than in London?—Which districts do you refer to?

12,018. The districts upon the south side?—All except one.

12,019. With the exception of St. Olaves, it is less than the density of London?—Yes.

12,020. And yet the zymotic death-rate is not nearly so high; in Northfleet it is higher?—No, I do not think so.

12,021. In Northfleet it is 3·43; but I was wrong in saying "the zymotic death-rate; look at the "scarlet fever" column; is it not the fact that in several of those districts it is higher than London; take Gravesend, Woolwich and Northfleet?—In those three places it is higher than in London.

12,022. Greenwich is nearly as high?—Greenwich and Dartford are both nearly as high.

12,023. In giving your opinion that the high death-rates in this column which you have particularized, "scarlet fever, measles, and diarrhœa", are due partly to the river as one of the causes, have you taken into consideration this density table which you have put in?—I have. I especially draw attention to the "scarlet fever" because, as I said, diarrhœa is caused chiefly by another means.

12,024. As I said, scarlet fever is highest in the Barking Town district which, as you have said includes a large district, besides the small town of Barking?—Yes, that is so.

12,025. In those districts is the area of the river taken into consideration in the acreage?—I am afraid I cannot tell you that.

12,026. Because if that were the case it would diminish the ratio of population?—No doubt.

Examined by the Commission.

12027. (*Dr. de Chaumont.*) In presenting these statistics to the Commission, do you merely present them as facts to be considered, or do you suggest it as your own opinion, that the sewage has an influence upon the death-rate?—I present them, in the first place, as facts to be considered, and in the second place, I give my own opinion that the emanations from the river must have some influence.

12,028. Do you think that the differences of the death-rate from scarlet fever, and so on, in the riparian districts, are due to the sewage in the river?—I believe that is one of the causes of the difference.

12,029. A material cause?—I do not know how far. I would say that——

12,030. Do you think it is the chief cause?—I should not like to go so far as to say that it is the chief cause. I do not think that I should be justified in saying that it is the chief cause. I think it is one of the principal causes operating upon the zymotic diseases upon both sides of the Thames.

12,031. Have you any means of eliminating other causes so as to appreciate the amount of causation of this river?—One way was that which the learned counsel suggested, that I should like a certain distance, say, a mile from the river, and take the death-rate within that limit; but that is obviously impracticable.

12,032. Have you had any data for eliminating other causes in forming your opinion, so as to estimate the relative amount of causation of the river and other causes?—I do not know that I can answer that. I can only point out that some of the districts which have only places near the river, give examples of very high death-rates. Dagenham, for instance, which I took out in order to avoid Romford, and which is all close to the river, has a very high zymotic death-rate, and an exceedingly high scarlet fever death-rate.

12,033. (*Professor Williamson.*) It is a low, marshy district, is it not?—A good many of them are low, marshy districts, but I do not know that that has much to do with scarlet fever.

12,034. Have you any statistics relating to the death-rate of riverine populations by rivers similar to the Thames, where sewage is not present in the river, or rather a comparison of the death-rate of such a population with that of a population lying a little farther from the river as in London?—I have not at present any such statistics; if I had had a little more time, I should have got out some.

12,035. Because it is open to persons to imagine that the greater unhealthiness of the riverside districts here may be due to the river itself, apart from the sewage it. What one would like to know is, whether it is the sewage in the river that makes the district unhealthy, or whether it is the river itself that does that?—I am afraid that I cannot answer that, except by saying that scarlet fever is very prevalent upon both sides of the river, which is not a thing which a low-lying district would have any special connexion with.

12,036. (*Sir P. Benson Maxwell.*) We have the fact that these are low-lying districts where your zymotic diseases are so high, and that they are also thickly populated?—They are not all thickly populated districts; those near London are.

*Prof. W. H. Corfield.*

14 March 1883

12,037. Those four instances, where the average is so much higher than that of London, are thickly populated places?—But I attach much more importance to the other districts than to the four first. I must, of course, attach much more importance to the districts below the sewer outfalls, and immediately about them, than to the first four districts which are really parts of East London.

12,038. (*Dr. Stevenson.*) Do you think that the emanations from the river cause there to be more scarlet fever, or cause it to be more fatal?—It is very likely that both those tests are true, but I cannot tell you as a matter of fact.

The witness withdrew.

SIR P. BENSON MAXWELL took the Chair.

Mr. BENJAMIN BROWNING, M.D., S.Sc. C. Edin. F.C.S. called in and examined.

12,039. (*Mr. Lumley Smith.*) I believe you are an M.D., and a member of several learned societies, and you are the officer of health for the vestry of Rotherhithe?—I am.

12,040. I believe you are also surgeon to two divisions of the metropolitan police, the "M," and the "Thames"?—I am to a subdivision of the "M" and to a sub-division of the Thames, the sub-division occupying the southern bank of the Thames.

12,041. You have given a good deal of attention I believe, also to matters connected with health?—I have for some years past as a medical officer of health.

12,042. You are a Fellow of the Sanitary Institution of Great Britain, and are upon the council of that society?—I am, and also on the council of the Social Science Association.

12,043. How long have you resided in the neighbourhood of the Thames?—For rather more than seven years.

12,044. Has that been at Rotherhithe?—The whole time.

12,045. During that time have you paid some attention to the condition of the Thames?—A good deal, having been connected with the sanitary department of my district, and with the Thames police for the whole of that time.

12,046. You have examined, have you not, for yourself, the water, and the mud of the Thames?—I have at different times and upon several occasions.

12,047. Have you from time to time taken samples of the water of the Thames for the purpose of examination?—I have.

12,048. Has that been done for the purpose of this inquiry, or for your own information?—It has been done for my own information, long before this inquiry was heard of, or at all events heard of by me.

12,049. Extending over what period?—Over the past five years.

12,050. Have you taken samples. I am not asking you for the details of your investigation at all; and have you examined them, and in what way?—I have examined them chemically, and microscopically.

12,051. Have you also from time to time considered how far you can trace any affection of the health of the people under your care to the condition of the river?—I have, having had under my care a large number of people who have attributed their illness to the smells arising from the river.

12,052. (*Chairman.*) You did not attribute it to that, but they did?—Yes, I did so in some cases where I investigated their statements.

12,053. (*Mr. Lumley Smith.*) Before I pass from this question will you tell me what number of police you have under your care?—I have 50 officers and men who live upon the south bank of the Thames, that is to say, of the Thames police, besides a large number of the land police.

*Mr. B. Browning, M.D., S.Sc. C. Edin. F.C.S.*

12,054. Have you in addition the medical care of any working men's clubs?—Yes, of a number of clubs, amounting to between 600 or 700 workmen in all.

12,055. What class of people are they composed of?—What we call waterside people, bargees, watermen, lightermen, boatmen, and people of that class.

12,056. So that you have a large number of waterside characters under your care?—I have.

12,057. Have you come to any general conclusions with regard to the effect of sewage as it is poured into the river?—I have.

12,058. What are the conclusions to which you, in your judgment, have come; will you give us them in succession?—The first conclusion to which I came was that a considerable portion of the sewage which is discharged into the river at the outfalls at Crossness and Barking is not carried down to the sea directly, but is brought up the river at least as high as Limehouse, if not higher. The second conclusion I arrived at was that whilst the sewage is thus retained in the river it undergoes decomposition, and becomes very injurious to health. The third conclusion was that the number of cases of various illness, such as fever, typhoid fever especially, scarlatina, various throat affections, general malaise, and sometimes diphtheria, as well as some cases of diarrhœa, are directly attributable to these emanations from this decomposed sewage.

12,059. And you have satisfied yourself of that after attending the patients and noticing the surrounding circumstances?—Yes, after attending the patients, and going out, in the case specially of the Thames police, by day and night at the same time of tide to which they said they had been exposed to those emanations.

12,060. With regard to persons subscribing to clubs, I suppose they are entitled to sick pay when they are ill?—Yes.

12,061. And their cases have to be investigated, have they not, to see if they are really genuine cases of illness?—Hardly that. I must accept their statements, or perhaps I might put it in this way. I of course investigate their case as a medical man, but as they are not in the same position to myself as the members of the police force, I put them upon the list, if they wish it, irrespective of my own judgment; but with the police it is different.

12,062. I presume you have kept no record of the individual cases amongst the clubs you attend?—No.

*Mr. B. Browning, M.D., S.Sc. C. Edin., F.C.S.*

14 March 1883.

I have only a list, which I have not very carefully kept, of the certificates that I have given that so and so was sick from such a time to such a time.

12,063. Now with regard to the Thames Police, what class of men are they with regard to age and physique and so on?—They are men in the prime of life carefully selected, of good physique generally, and with good hygienic surroundings in their houses; most of their houses are personally known to me. I have invariably made a rule of inspecting every house in my district in which police officers reside, should illness occur there.

12,064. Then they are people less likely than others to be affected by surrounding circumstances?—Undoubtedly.

12,065. Now with regard to the cases of illness, is there any temptation on their part to sham being ill when they are not?—It is quite the other way.

12,066. Why is that?—Because a considerable portion of their pay is stopped when they are ill.

12,067. They are fine strong young men, and they are fined when they are ill?—They are.

12,068. Have you found in the case of the police instances of illness or indisposition, which you attribute to the condition of the river?—Several.

12,069. Can you tell me about how many?—During the last 5 years out of an average strength of 50 men, who in those five years gave me 146 cases of illness from all causes, I have had 18 cases of various forms of illness, which were attributable, to the best of my judgment and in the belief of the men themselves, to the emanations to which they had been exposed while on duty on the river.

12,070. (*Sir John Code.*) Do you mean on the river or by the river?—On the river.

12,071. (*Dr. Stevenson.*) What part of the river do you refer to?—The part from London Bridge to Barking, the majority of my men being employed between London Bridge and Greenwich, but all of them being from time to time sent on duty as far as Barking.

12,072. (*Sir John Code.*) You attend all the river police, do you not?—I have one sub-division of river police and another of land police.

12,073. Have you found much difference between the river police and the land police?—Yes, in respect of illness. Although the Thames Police are the younger and stronger of the two, there is much more sickness amongst them than amongst the land police, the same conditions existing as to stoppage of pay when sick, and the hygienic conditions being about equal.

12,074. Could you give the Commission an idea of about in what ratio they would average one to the other?—Roughly, two to one. Out of every three policemen I have placed upon my sick list from the Thames and the M police, where I have one M policeman I am sure to have two Thames men.

12,075. Would that apply over the whole period during which they have been under your charge?—Yes, which is within a few months of seven years.

12,076. (*Mr. Lumley Smith.*) I understood you to say in speaking of these cases, which you attributed to emanations from the Thames, that you were not speaking of exposure to weather?—No, I have carefully eliminated all those. I have the particulars taken from my books if it is required of the exact maladies from which those men were suffering. (*A copy was handed to Mr. Bidder*).

12,077. You have told us you have seen the sewage ascending the river and so on; are you judging by the eye, or in what way do you judge?—I judge by the eye, smell, touch, also by the microscopical, and chemical evidence.

12,078. Have you taken any specimens of mud from the banks?—I have.

12,079. At what places?—At various places near the outfalls, and also as high up as Wapping, and at the Surrey Commercial Docks at Rotherhithe.

12,080. In what condition did you find the mud?—I found it black and very fœtid.

12,081. Did you find evidences of sewage?—To the best of my knowledge and microscopical observation, I did.

12,082. Do you find, going back to the question of health, that the health of your patients varies between summer and winter; do you find at any time of the year any symptoms of disease or illness which you attribute to the river?—Yes, in the hot months I get certain diseases both amongst my water police and amongst my club patients which I do not find at other periods of the year.

(*Mr. Bidder.*) Is not that true everywhere.

12,083. (*Mr. Lumley Smith.*) Are you able to compare those patients with the patients who live away from the river?—Yes.

12,084. Do you find those symptoms more prevalent or less prevalent with the people who are nearer the river than with those who are further back?—I find with regard to the police that while I am having these special complaints, which I have termed "riverine" complaints among the water police, the same complaints are not found among the land police; I find that amongst my club patients, whilst the lightermen and those employed upon the river, and also (in former years, not lately, since the Canal Boats Act has been passed) the children of bargees and those on canal boats plying on the river, are subject to "riverine" complaints, a similar class of people working in the docks, such as the Surrey Commercial Docks, seem to escape from those complaints.

12,085. What is the nature of those complaints?—A special form of sore throat, a great deal of malaise and languor, a sort of ill-defined fever, and more or less diarrhœa. I have found diphtheria distinctly attributable to it, and in some cases (where I was able to trace the cause), typhoid fever.

12,086. As you were able to trace the cause, what cause did you trace the typhoid fever to?—The typhoid fever has been evidently traceable to drinking the Thames water from alongside ships, which has been sometimes done.

12,087. Do you know the fever-rate in your parish; your parish is Rotherhithe, I suppose?—Yes; my parish is Rotherhithe.

12,088. That is a portion, is it not of one of the districts Dr. Corfield has been giving us?—That is a portion of the St. Olave District. I was looking at his tables, and I find he has not worked it out specially.

12,089. Can you give us the fever-rate in your parish?—The annual average of the zymotic death-rate, which I presume is what you mean by the fever-rate, has been for the last 10 years, from 1871 to 1880 inclusive, 3·83 per 1,000.

12,090. Is that high or low, as compared with the general average of London?—It is higher than many other corresponding riverine districts. I have not the figures, but it will be found from the reports relating to corresponding riverine districts, with a poorer population too, above London Bridge to be considerably higher than those.

12,091. It is rather below the whole of London as given by Dr. Corfield, but you say it is high as compared with what?—It is high as compared with some corresponding parishes higher up the river. The fact of its being below the average of London may be accounted for by the fact that I have succeeded in removing a great many cases to the hospital, so that the actual mortality in my parish has not been so much as it might have been.

12,092. I presume a great many of those cases of illness do not cause death?—No, they do not.

12,093. Have you any hospital in your district at all?—We have a large workhouse hospital making up, I believe, 400 beds, and receiving people from the whole of St. Olave's.

12,094. You have no fever hospital or anything of that sort?—No, not in my parish; the nearest is some distance beyond.

12,095. Then the fever cases in your parish you pass out of your parish to somewhere else?—A few

of them; those that I am able to obtain information of and to convey to hospital when necessary.

12,096. Of course every case of fever that goes away from your place and terminates fatally would of course decrease your fever death-rate?—Yes, of course; the bad cases I am unable to send; the slight ones I experience great difficulty in doing.

Cross-examined by Mr. BIDDER.

12,097. You are medical officer to the Thames Police?—I am, to one of the sub-divisions.

12,098. Have you anything to do with the "Royalist"?—No.

12,099. That is a vessel moored in the river?—I think you will find that she is on the bank and not moored at all.

12,100. Whereabouts is she located?—Below my district; she is on the river side; I have seen her often.

12,101. She is occupied by the Thames police, I believe?—By one or two; if there are four altogether, that as is many as there are.

12,102. Do you happen to know that their health is remarkably good?—No, it is quite the other way, I imagine, because I have had men coming thence and complaining of the situation.

12,103. Have you anything to do with the inspection of the "Royalist"?—No; but have often had men who have been in the "Royalist," who have been transferred to my division, and I have noted that they have not been in good health. One of the cases I gave you a list of came from there.

12,104. You handed me a list, this is an extract from a book; would there be any difficulty in producing the original book?—I think so. Orders are given to the inspectors and superintendent, that it is to be kept at the police station; it is taken to my house every morning, and when it is done with it is brought back again.

12,105. (*Chairman.*) There would be no objection, would there, to letting Mr. Bidder see the book if he wishes it?—I have nothing to do with it; the book is not in my custody, it is in the custody of the Superintendent of Police.

12,106. (*Mr. Bidder.*) These figures are spread over five years?—Yes.

12,107. And you picked those out of 146 cases referring to the Thames Police?—Yes.

12,108. Last year you were only able to find two cases which you could in any way attribute to the river?—Yes.

12,109. One of those was an abscess?—Yes, one was a case of abscess and blood poisoning.

12,110. Is an abscess a thing that could fairly be attributed to the Thames?—Most certainly, when, as in this case, it is the result of blood poisoning which I and the patient attributed to the inhalation of various smells.

12,111. Which came first, the abscess or the symptoms of blood poisoning?—The symptoms of blood poisoning.

12,112. I do not know much about it, but I have heard of blood poisoning in people who do not live near the river Thames; does that happen?—No doubt it does in people affected by the special poisons that produce blood poisoning.

12,113. I see that in the whole five years you only had five cases of blood poisoning and one of them was a case of dyspepsia?—Certainly; blood poisoning, as a rule, does not affect strong healthy men. Their *vis vitæ* enables them to escape in many instances, even when exposed to its influencing causes.

12,114. Have you cases of blood poisoning in your land police?—I do not remember one.

12,115. Have you a similar record of their cases?—I have a similar record of their cases.

12,116. Upon what ground do you make the statement, and upon what statistics that you have two cases of sickness amongst the Thames police for one amongst the land police?—I stated that it was a rough calculation, and from memory.

12,117. Rough or not, a calculation implies figures you know?—No doubt. That idea is taken from the sick books of the two divisions.

12,118. What were the figures with regard to the two divisions?—I have not worked up the land figures. I cannot say at the moment, but I know as a fact that that is about how they average.

12,119. You cannot know that as a fact unless you have worked it out?—We know many things as absolute facts in every capacity of life which we may not be able to give the exact figure for on the spur of the moment.

12,120. Do not let us waste time in dealing with truisms. As a matter of fact, for instance, how many cases have you had in the land division in the last five years?—That I cannot say upon the spur of the moment; I have not added them up, but they are very much fewer than in the Thames Police Sub-division.

12,121. How many men have you in your land division?—Nearly 100; between 80 and 90.

12,122. You have also, I presume, no objection to our inspecting that book?—I have nothing to say to it; it is not in my custody, and never is; it will be a question for the Commissioner of Police.

12,123. You have stated that you have had two cases of sickness amongst the Thames police to one amongst the land police; now I ask for the figures upon which you base that statement?—If I had known the question would have been asked I should have been most happy to have extracted the figures and sent them in.

12,124. With regard to the two cases of blood poisoning I am glad to see they were not very serious; one gentleman was back at his work at the end of the week and the other after no very long time?—In both cases the men had been ill before they were put upon the list.

12,125. Now you used the term malaise; I am not a doctor; what sort of disease is that?—I think, though it is difficult to define positively what it is, we most of us know what it is. If I were obliged to translate it I should describe it as being a condition of "alloverishness."

12,126. It is, I believe, sometimes used to describe the feelings of a gentleman who has been out to an entertainment the night before. When the Noxious Vapours Commission was sitting the term was used to describe the condition produced by the exhalations of factories and things of that kind?—That I cannot say, as I was not connected with that Commission.

12,127. You have a good many factories in Rotherhithe, have you not?—I cannot say that we have many.

12,128. There are a good many in Rotherhithe and Bermondsey, are there not?—The Bermondsey factories lie a long way from the river.

12,129. Those 18 cases are the entire number of cases of sickness you could in any way attribute to the influence of the river amongst 50 men in five years?—Not in our view; I have carefully eliminated all doubtful cases.

12,130. Those are all the cases you could put down as being attributable to the river?—Those were all the cases which I was quite clear were brought about by the emanations from the river.

12,131. (*Sir John Coode.*) If you say you are quite clear about those 18 cases, how many doubtful cases would there have been?—I should say quite half as many again.

12,132. Now here is another case—"stomach and liver disease." I am talking about a thing that I do not understand, but is that a sort of thing that comes from a bad smell in the river?—That is a case which I have only shown once,—a case of derangement of

*Mr. B. Browning, M.D., S.Sc. C.Edin., F.C.S.*

14 March 1883.

the stomach and derangement of the functions of the liver,—the symptoms were apparently due to the derangement of the functions of the liver and stomach, which I could attribute to nothing else but exposure to the smell of the River Thames, that case is shown as one case only; it should really have been shown as six or seven cases, for the man was upon the list six or seven times in addition to that entry, and for the same ailment.

12,133. If you tell me that stomach and liver diseases are likely to arise from a river smell I will believe you implicitly?—In this case there can be no doubt about it.

12,134. Another gentleman had stomach disease, that was attributed to the river?—Yes, that case was so serious, and lasted so long, that he was discharged from the service in consequence.

12,135. There are several gentlemen who suffer from diarrhœa in the summer months; how are you certain that that is attributable to the river, and not to the many causes which do produce diarrhœa to persons who are not upon the river during the summer months?—The men were in good health, and had not committed any error of diet.

12,136. How do you know that?—From their statements.

12,137. That is a strong statement to make; their views of diet might not be identical with yours?—I took it from their statement of what they had eaten.

12,138. Did they say what they had drunk?—In that list I have put down no case of diarrhœa unless a man was or professed to be a teetotaller.

12,139. But sometimes that is a cause of diarrhœa, is it not?—Not to my knowledge.

12,140. Now I see that another of the 18 cases is put down as gastritis, is that a sort of thing which is likely to come from a river emanation; if you say it is I will believe it?—There was irritation of the stomach which is one of the complaints that may fairly be attributable to the sewage emanations, and this man had been employed in the lower part of the Thames at low tide, and complained very much of the smell of the banks.

12,141. (*Mr. De Chaumont.*) Was he a teetotaller too?—Yes.

12,142. (*Mr. Bidder.*) Are the teetotallers in the police like six-day cabs marked with a particular kind of number?—No; they have simply their divisional number, which is precisely the same whether they are total abstainers or otherwise.

12,143. You say you find that the people who work in the docks are, as compared with others, particularly free from this disease?—I find that the people who work in the docks at the same time in the summer, members of the same clubs as I have spoken about, working about over the water all day long, but being simply in the docks and not employed up and down the river at different times of the tide, are free from these stomach affections.

12,144. What do you attribute that to?—I believe there are certain special affections which are produced by the emanations from the river, and that the people not exposed to those emanations do not contract those diseases.

12,145. I suppose you are speaking of the Surrey Commercial Docks?—Yes.

12,146. Are you aware that the docks are filled with their water from the river?—I am. I see it running in there from time to time.

12,147. And at high water when, if ever, it is most charged with sewage from below?—I do not know that; I simply know that they are filled from the river at high water.

12,148. If it is true that the river in your neighbourhood is polluted by our outfalls, the pollution must be principally at high water, and not at low water?—I do not think so.

12,149. I suppose you know that at low water, the water that comes down comes from above, but at high water it comes from below?—Yes, so it does; at the turn of the ebb tide; it comes from below at the end of low water with a young flood, and then I believe at young flood most of the pollution is brought up.

12,150. (*Mr. Abernethy.*) You refer to the Surrey Commercial Docks, do you not?—I refer to the Surrey Commercial Docks simply. I know nothing of any docks upon the north side of the river.

12,151. (*Mr. Bidder.*) Now with reference to typhoid fever, you have had a certain number of deaths from typhoid fever in the Rotherhithe District, have you not?—Yes.

12,152. Is it the fact that none of those deaths occurred in the district immediately contiguous to the river, but farther back; for instance you know Rotherhithe Street—that is a long street that runs parallel to the river, is it not?—Yes.

12,153. Is it the fact that all the deaths from typhoid fever occurred farther away from the river?—I cannot say that. I think Rotherhithe Street has always had its fair share of mortality of all sorts.

12,154. Now I see that you as a medical officer of health indulge in an annual report like other people?—To the limited extent permitted me by the vestry.

12,155. I am sorry to hear that your vestry does not allow you carte blanche, but to that limited extent I see that you avail yourself of it. I have one dated the 31st of December 1879; is that the last you made?—No, I have written three since then.

12,156. You begin by saying, "I will remind you "that in 1856 Rotherhithe was supposed to be one "of the most insalubrious suburban districts, being "almost entirely unsewered, marshy, with a scanty "water supply, and that so contaminated, as to be "usually refused even by horses."

12,157. (*Chairman.*) Was that so?—It was not within my own knowledge, but I took it from the reports of my predecessors.

12,157. (*Mr. Bidder.*) A great deal of that has been changed, but what I want to come to is that the marsh still exists, does it not?—No; it has been done away with.

12,159. You have not raised Rotherhithe bodily, have you?—No, but from time to time the marsh has been drained as it was built over.

12,160. (*Sir John Coode.*) When was that drainage carried out?—From 1856 to the present date.

12,161. Spread over the whole period?—From then down to the present time, till now when there is not a quarter of an acre of it that is not drained.

12,162. But it must have been done very gradually, if it was spread over that time?—The Vestry Reports give the proportions in which it was completed.

12,162. (*Dr. Stevenson.*) But when would it have been practically finished?—Not until now, because Rotherhithe has been very much built over lately, and of course house drains are not made until houses are built.

12,163. (*Sir John Coode.*) Then it has not been a regular system of drainage undertaken and carried out, but as the buildings were built so the drainage proceeded?—Precisely.

12,165. I understood that there had been one broad system of drainage regularly undertaken and carried out, but you mean to say it was carried out gradually as the buildings were completed?—Precisely the house drainage.

12,166. (*Mr. Bidder.*) Now will you let me ask you if this is correct, that—"The gross death-rate "was 23·2 per thousand per annum, but the large "number of non-residential deaths recorded (owing "to the reception of paupers from other districts into "the St. Olave's Workhouse, the frequent accidents "occurring to strangers in the Docks, and the many "bodies from the Thames which you have to receive "and inter) greatly reduced this, and following the "method pursued by both my predecessors, I have "computed the 'corrected death-rate' of 1878, as "18·8 per thousand." Is that correct?—Yes.

12,167. I see you have added a very useful note that you can turn the rate per 1,000 into a percentage

by simply moving the decimal point one place to the left?—For the edification of my masters following the example of the Registrar General.

12,168. "Whilst therefore our total corrected death "and child rates have diminished since 1877, and the "former is lower than in either London or Greater "London, last year's metropolitan death rate is higher "since 1877 by 1·6 per 1,000, and the mean of the "23 large towns by 1·4 per 1,000. In the same "period our mortality was but 2·6 per 1,000 beyond "that of the healthiest large town mentioned by the "Registrar-General (Dover, with a death rate of "16·2), and 10·8 per thousand lower than the most "sickly (Dublin, with 29·6)." "Rotherhithe, you "will probably agree with me, is not insalubrious." Is that your opinion still?—Quite so from these figures; these figures merely give the death rate; the death rate is one thing and the sickness rate is another.

12,169. No doubt, but a statement is a statement, and I ask you whether you still adhere to that statement, and invite us to agree with you that Rotherhithe is not insalubrious?—That is so.

12,170. That is your opinion still that Rotherhithe is not insalubrious?—I am still of opinion that Rotherhithe is not insalubrious as far as regards the death rate.

12,171. We know what insalubrious means,—everybody knows what that means. By the bye you have added certain things, and I must ask you a question that will militate with your death rate, but has nothing to do with the main drainage outfalls; for instance I see you mention a well-known piece of stagnant water, called "the mill dam," which you say was in a very offensive condition?—Quite so; if you will read on further you will find that in that year it was piped and drained and put into repair, and it is now abolished altogether, it is not in existence at present; you are speaking about 1878. This Report goes back to 1878, and many improvements have been made since. This mill dam was one of them, and that has been emptied within the last quarter, but at the time of that report it was just being put into a proper condition, the sewage was being diverted from it, and it was being systematically cleansed and so on.

12,172. Another thing I see which has some bearing upon the question is that the water of which you took samples near Rotherhithe you found polluted sometimes?—Certainly.

12,173. Let me ask you if this correct, "My atten- "tion was next directed under the "Rivers Pollution "Act, 1876," to the numerous privies and drains dis- "charging into the Thames, and with your sanction "preliminary steps were instituted for their removal." That leads me to ask you is it the case that there are instances where there are numerous privies and drains discharging into the river?—No, all those that you have been referring to have been cut off.

12,174. Have they all been cut off?—They have now, but that report was written in the beginning of 1879.

12,175. All you say in your report is that you have taken some preliminary steps for their removal, so I gather from those words that their removal is something accomplished since then?—That was so.

12,176. I see another thing you describe with great eloquence: "A horrible and dangerous nuisance, "caused by a person, named Judd, collecting, to an "enormous extent, fish refuse for manure making in "several arches of the South-eastern Railway (and "mentioned by the Local Government Board In- "spector in his First Report on Noxious Trades,) "was partially put down."——

12,177. (*Chairman.*) But that was in 1878; has that been put down?—Yes, but that was not upon the banks of the river.

12,178. (*Mr. Bidder.*) I see we have not quite got rid of Judd, because he is described as occupying premises and collecting garbage there?—At present he is occupying a cell in one of Her Majesty's gaols.

12,179. Then that is something recent; now will you tell us what your death rate was for last year?—I can tell you what it was for the year 1881. I have not been called upon for my report for 1882 yet.

12,180. What was the death-rate for 1881?—I think the corrected death-rate was 18·7.

12,181. That is a little bit better than this very excellent year?—Yes, but that is the death-rate and not the sickness rate; all my evidence as to this river illness relates to sickness; I have not a single case of death to refer to.

12,182. (*Sir John Coode.*) Can you hand us any statistics as to the sickness rate?—No, it is quite out of the question, because so much sickness, especially zymotic sickness, is so carefully concealed that any statement I could prepare would be perfectly valueless; it would not even give an account of the sickness among the pauper population.

12,183. Have you any of your later reports?—There are three more printed, another is in the printer's hands.

12,184. I see that you attribute a good deal of the illness that you have to the "concealment of mur- "derous ailments like small-pox, scarlet fever, diph- "theria, and so on systematically in better families "encouraged by advisers from whom better counsel "might have been expected"?—Yes.

12,185. I have been looking through your report, and I do not find in your report of the district any suggestion whatever that any of the illness of the district is attributable to the Thames?—Certainly not; that report was written for the vestry.

12,186. Do you not tell them the truth at the vestry?—I do, but I do not always tell them the whole truth; they do not want to be told.

12,187. (*Chairman.*) Was not it part of your duty to call attention to the causes of disease in your report?—To a certain extent it was, but I have always found that if I presumed to offer anything but limited advice in my report they usually refused to accept it.

12,188. (*Sir John Coode.*) When you say to a certain extent you reported to the vestry, where do you draw the line between what you report and what you do not report; you report facts simply, do you not?—I report facts.

12,189. And you abstain from giving advice or calling attention to the causes of certain effects?—Not altogether, but I find that if I make a statement having reference to the duties of other bodies my vestry decline to go into that.

12,190. (*Mr. Bidder.*) But I find you go pretty largely into causes?—As far as I consider they come under the province of my vestry I do.

12,191. You point out all sorts of causes of disease, but you never suggest that any are attributable to the river?—That is so.

(*Chairman.*) You do point to other causes of disease?—Yes.

(*Mr. Lumley Smith.*) Those were the causes which were under the control of the vestry.

(*Mr. Bidder.*) Not all of them.

12,192. (*Sir John Coode.*) I presume that is what the witness means?—I mean that decidedly.

12,193. (*Chairman.*) You mean that in pointing out the causes of disease you limit yourself to causes which are under the control of the vestry?—That is so, and were I to do otherwise the vestry would not appreciate it; they do not want to be brought into collision with other bodies.

12,194. (*Mr. Bidder.*) For instance, the way in which people conceal disease is hardly within the province of the vestry, is it; they can do nothing to check the concealment of disease. And again, I find you go out of your way to describe causes in which you say the vestry can do nothing, you say, "I made "the customary half-yearly inspection of slaughter- "houses and cow-houses," and so on, and having suggested an improvement you go on to say that "the "sanitary authority are powerless to effect such an "alteration"; that is one case in which you did go

*Mr. B. Browning, M.D., S.Sc. C.Edin., F.R.S.*

14 March 1883.

" outside your authority?—That is one of the occasions on which I was politely warned to mind my own business when mentioning such a body (as I did) as the Metropolitan Board of Works. Several members of the vestry told me plainly that I had nothing to do with the question of the Board's powers—nor with the registration of disease.

12,195. (*Dr. Stevenson.*) But surely the vestry have to do with the licensing of cow-sheds?—Nominally, but really it is only a farce; they will not take an active part in the matter.

12,196. Do not your subordinate officers examine the cow-sheds?—Yes, and I do myself, but still it is a perfectly useless thing for me to do, since my recommendations are not always acted on.

12,197. It is a part of your duty?—Yes, it is a part of my duty.

12,198. (*Mr. Bidder.*) You told me just now that all these privies and drains in your district running into the Thames had been stopped up?—Yes, I told you that as far as I knew they had been.

12,199. Are you aware that in his report for 1881 Mr. Collingridge reports 19 foul outfalls within your district of Rotherhithe?—I am not aware that he did so, and I think with all deference to him that they did not exist in 1881, where I specially examined the Rotherhithe foreshore looking for them; I will not say they have not been again opened since.

Re-examined by Mr. Lumley Smith.

12,200. One word upon the list of cases which you handed my learned friend; you stated in answer to me, that there were only two cases in 1882; that is so, is it not?—That is so of cases which I could distinctly attribute to the river.

12,201. That was a very cold year, was it not?—That was a very cold year.

12,202. You find, as I understand, no cases that you can absolutely attribute to the river in the months of November, December, January, and February?—That is so, with one exception, where a man who, I think, afterwards left the service, was taken ill in March, but he had been to me several times before that; in the previous autumn he had been to me.

12,203. (*Chairman.*) With that exception there were no cases upon the list mentioned by Mr. Lumley Smith?—I think not. There is one more in the month of February, but that man had been to me several times in the previous autumn. I might have made that list much larger if I had put down the same men two or three times over, which I might have done, as they have often come back.

12,204. (*Mr. Lumley Smith.*) Now I will ask you one general question with regard to typhoid fever; you have no typhoid case there?—No.

12,205. Is it the fact that typhoid fever comes usually from drinking contaminated water, and not from emanations from the river; is that a fact or not?—I believe as a rule typhoid fever is brought on by drinking poisoned water. I mean water poisoned with the " contagium " of that fever.

12,206. Now with regard to Rotherhithe being salubrious; are some parts of Rotherhithe more salubrious than others?—Yes, of course the more open and better built parts are more healthy than the poorer and more crowded parts.

12,207. Comparing the parts near the river with the other parts, which are the most healthy?—The parts farther back, decidedly.

12,208. With regard to your nuisances, you do not agree that there are 19 foul outfalls in your district?—I am not aware of them.

12,209. The only nuisance left is the Thames?—I think that is the chief nuisance.

The witness withdrew.

Professor John Thomas Way, F.C.S., recalled; further examined by Mr. Balfour Browne.

*Prof. J. T. Way, F.C.S.*

12,210. You are aware, I think, of the various estimates which are formed by the engineers of the proportion in which sewage may at any time be present in the river?—Yes, I have heard the evidence.

12,211. Will you tell us what proportion of sewage in the water would, in your opinion, make it so foul as to become a nuisance?—I should say that from three to five per cent. would certainly make it foul.

12,212. (*Professor Williamson.*) May I ask, have you made a mixture of sewage with water in known proportions, and taken occasion to observe the properties of this mixture, and can you say whether the opinion you have expressed is founded upon definite observations?—It is. You well know I have been engaged upon sewage questions all my life, for the last 40 years, and I have had, I think, quite as great opportunities as any other chemist of dealing with sewage; therefore, when I speak I do not speak from any individual experiment, but from a general knowledge of the subject, that has been done over and over again.

12,213. You have found mixtures in such proportions as those to be offensive?—Yes, in my laboratory at this moment I have a mixture of 10 per cent., but that is a very offensive mixture.

12,214. (*Chairman.*) You say that from three to five per cent. also would be a nuisance?—Yes.

12,215. (*Mr. Balfour Browne.*) Assuming that from three to five per cent. is poured into a river, even of the same bulk as the Thames, at the outfall, you think it would become a nuisance?—The larger the bulk the greater the nuisance. I think the quantity poured in, which is a known quantity, is very large for a river of the size even of the Thames, which is a large river.

12,216. The total weight of offensive matter which you say is discharged into the Thames is, as you say, very considerable?—Yes; I have made a great number of analyses of the sewage of the Thames; there were a number which were made for the Metropolitan Board of Works, which I do not believe are published, but they were made, and made very carefully. They were made for the Metropolitan Board of Works in connexion with the International Financial Society, in connexion with the Essex Reclamation.

12,217. What is important in this connexion is, as I understand, to tell what is becoming of the sewage so discharged?—Yes.

12,218. Have you directed your attention to that; do you think the liquid portion is the most important portion to consider?—I do not consider it so.

12,219. Would you just say why?—Sewage may be roughly divided into three parts; the liquid portion, the heavy part which comes from the detritus of the streets, and the light flocculent part, which, in great measure, comes from the fæces, the indigestible portion of the fæces. The greater part of the light floating matter, no doubt, comes from the fæcal matter of the body.

12,220. Is there some of the matter soluble, and some insoluble?—Of natural fæces, as discharged from the body, there is a portion soluble in water, it is not a large portion, perhaps 10 per cent., the rest is insoluble.

12,221. Of the history of the insoluble is much known at the present time?—Its composition and its character, of course, are well known, but what becomes of it in the river, especially in a tidal river like the Thames, cannot be known, simply because it is partly swept away with the liquid, and partly subsides.

12,222. With regard to the insoluble matter, what do you mean precisely by that term?—I prefer to take sewage as if it were nothing but fæces and urine, for, practically, that is what it is. Of course all sorts of other things get in, but as compared to those two sources, the other sources are very small indeed.

12,223. (*Sir John Coode.*) And comparatively harmless, would you say?—I do not say that at all, because there are all sorts of nastinesses get in, but taking it in the gross, and taking a common sense view of sewage, I think that is a fair way to look at it.

12,224. (*Mr. Balfour Browne.*) For the purpose of your calculation you are leaving out of consideration all the road detritus and débris?—Yes.

12,225. For the purpose of discovering what causes shoals in a river, that might be very important?—It would be very important.

12,226. But as regard nuisance to health that is unimportant?—It is quite unimportant how far the discharge into the river goes, except so far as regards that which is organic. Of road detritus, I do not care what proportion is discharged; I prefer to get at it by seeing how many people contribute to the sewage.

12,227. Upon that point you made an investigation to find out how much substance passed from the body; that was referred to by Dr. Tidy, but you can give us the substance of it?—I calculated from the results of observers generally, and from some of my own, that the quantity of solid fæces about which I am speaking now, per head of the population was 1,750 grains, which is a quarter of a pound.

12,228. Of solid excrement?—Yes, of solid excrement in a liquid state, that is to say with its water.

12,229. (*Sir John Coode.*) Is that per head?—Taking the average of every head of the population daily.

12,230. (*Mr. Balfour Browne.*) Of this quarter of of a pound, how much is actually dry matter?—One-fourth of it.

12,231. Twenty-five per cent. is actually dry matter when the moisture has been god rid of by drying?—Yes.

12,232. That makes it an ounce of dry fæces per head per day?—Yes.

12,333. Under these circumstances every 16 persons would contribute one pound?—Certainly.

12,234. And every 100 persons 6¼ lbs.?—Yes.

12,235. Have you calculated how much under these circumstances of dry fæces would be sent into the Thames per day?—Take the figure as you gave it just now of 16 persons to one pound, it is very easy to see that there would be at that rate, taking the population roughly at 4,000,000. (I wish it to be understood that these are quite rough figures. I do not see any use in pretending to get the figures with minute accuracy), it makes it 110 tons for the whole population of London per day of dry fæces.

12,236. And taking the dry and the moist together, it would be over 400 tons?—Yes, but that is not quite what I am endeavouring to lay before the Commission. The quantity I have stated is dry matter of fæces, but of course there is no dry matter of fæces in practice; it is merely to give the figure which has been asked for, but the dry matter is not what you have to do with; therefore the next estimate is that four times that is what would be the real quantity of wet fæces that found its way into the river, which gives you 1,000,000 lbs. or 400 tons of actual fæces a day; that is to say, fæces, which, if stirred up in a great lake would remain 400 tons of solid matter floating about.

12,237. (*Chairman.*) I make it 440 tons?—I take the 40 tons off for the soluble constituents.

12,238. You take it at 400 tons, allowing for the loss of the soluble constituents?—Yes, that figure I may say of a quarter of a pound per individual has been very much adopted; many methods have been attempted to find out the quantity.

12,239. We had some German authorities cited before us?—Yes, but amongst others, Mr. Lawes and Dr. Gilbert, whose names are known to the Commission, attempted to determine the quantity of sewage of a town by reference to the food, and what became of that food; that is to say, a statistical and physiological inquiry, and they came to very much the same results. There were books and volumes of reports, as you know, upon these subjects. That and the attempt to determine by actual experiment, collecting the sewage, are two methods; the third is to take simply the solid and liquid excrement, and make a fair guess at it, and calculate from it; that is the one I have adopted.

12,240. (*Mr. Balfour Browne.*) Seeing, as you believe, that that is the actual amount thrown in every day, is that, to your mind, a very startling amount to be turned in a river, even of the volume and size of the Thames?—It is an enormous amount; take a simple calculation; 400 tons or 400 cart loads; if you distribute that over the whole 24 hours, you find that there is a cart load going every three minutes. I do not believe the public would have borne it if it could see it. It is the fact that it goes in in a manner that is unseen—

*Mr. Bidder* objected to the evidence as being beyond the scope of the witness.

12,241. (*Mr. Balfour Browne.*) What, in your opinion, becomes of the insoluable or organic matter of the sewage, because that, you say, is the most important matter to be considered in this inquiry?—I think the light flocculent matter, when it is discharged into the river, moves up and down with the tides, depositing its heavier portions. It gradually meets with the actual mud or clay of the bottom, which has a strong tendency to combine with it. Aluminous matters have a tendency to combine with organic matter; so it becomes heavier and sinks, especially in slacks and places where the banks are formed; and in that way a great deal of the solid matter fails to go with the liquid matter; so that in fact it must be accumulating at the bottom of the river. I think, also, in fact I know, that if you shake up some mud that has been collected from the bottom of the river it settles very much faster than ordinary sewage.

12,242. Do you know whether there are large deposits of this organic mud, if we might so call it, at the bottom of the river?—Yes, I know there are, because I have seen them; of course I do not know anything about their quantity, or anything of the kind.

12,243. But you know it is there, and you say that, chemically, the light organic matter is apt to combine with the aluminous matter and sink?—Yes.

12,244. Is it your opinion that this mud is a more serious source of nuisance than the soluble part of the sewage that you have been mentioning?—I do, for this reason, because the soluble part (at what rate I do not know, because I have not heard the engineers' evidence, nor read it), is sooner or later taken away with the water of the river; but it would not at all surprise me that a very large proportion of this fæcal matter is collecting at the bottom of the river in different places. What happens is this. Supposing it to be once collected, it undergoes fermentation there, and produces gases which are some of the most noxious and objectionable; the nastiest gases at all events, of any organic matter; and when that mud is stirred, it comes up and gives off that gas. It goes down again to the bottom, and produces more, and it must go on doing that until it is entirely destroyed in whatever time that may take up. But the liquid matter of sewage is already in a state very far advanced in oxidation, it is on the point of passing into other materials which are not objectionable gases. It smells very nastily at first, but the oxidation undoubtedly destroys it. You will see that in this way, if you take some sewage and water, and pour it into a deep vessel, and stand it in a warm room, after a day

*Prof. J. T. Way, F.C.S.*

14 March 1883.

or two it will cease to smell, that is to say, the nastiness at the top getting oxidised without smell. If you pour off the liquid, and then stir up the little drop of liquid pure sewage at the bottom, you get an abominable smell at once; that is to say, that all the while the solid refuse is going on decomposing and producing noxious gases.

12,245. To follow out the description of that experiment, would this mud in the Thames be much more offensive when it was stirred up?—Undoubtedly, it only becomes offensive when it is stirred up, or when the gases escape by themselves.

12,246. At what time of the year do the gases escape more readily?—In the four or five warm months in the year. You positively see the black mud coming up to the top of the river, and the bubbles exploding; so also in stagnant ponds, you see the black mud which is produced in the same way.

12,247. This theory of yours that the solid organic material of the sewage is more productive of injury than the liquid, is not a new theory at all, but has been produced by you in a report as long ago as 1854, which you wrote to the Royal Agricultural Society?—That was so.

12,248. And you have seen no cause to change that theory up to the present?—No, I believe fully, it is perfectly well known, that the deposits upon the banks of the river were the cause of the stench. When the river was full there was not nearly so much smell.

12,249. Even although at the present time there may be no smell from the river at all, would the mud at the bottom of the river be in such a condition that when the warm weather came and brought it to the surface, the nuisance would then arise?—Yes.

12,250. Is it your view that under these circumstances, seeing that we have had evidence that the mud is accumulating, the condition of the river will be a very serious matter in years to come?

12,251. (*Chairman.*) Perhaps we had better say, if it should go on accumulating, will it, in your opinion, become a serious matter. I think the witness's opinion is that it is very bad at the present time and we may assume that if it becomes worse he will be of that opinion still?—That is so.

12,252. (*Mr. Balfour Browne.*) I believe you want to make a correction in your chlorine tables?—Yes, it is a correction in the lithograph table, the resumé of the chlorine experiments. At Deptford in the upper part of the table, the chlorine at low water is put down at 4·9, instead of 49·0; that has been corrected in some of the copies, but where it is repeated at the bottom of the table the error has not been corrected.

12,253. You thought that upon the last occasion the relation of chlorine in sea-water, sewage, and river water, was not made clear enough; have you any thing to add as to what you said as to that?—I am not aware that I said much about it at that time, but I would point out that as the experiments upon chlorine were mainly intended to see where sea water and where river water was in the river it was absolutely necessary therefore that they should be correct, and that therefore the question of the influence of the chlorine in sewage upon the quantity, should be taken into account; I wanted to point out that I had myself not taken it into account, and for this very simple reason. The chlorine in the river water is in 100,000 parts something less than two.

12,254. (*Chairman.*) 1·7?—Yes, 1·7; the proportion of chlorine in the sewage is certainly not more than 20. Dr. Frankland and Dr. Tidy put it down at 10. My impression is that it is higher than that, but it is certainly not more than 20, and the chlorine in sea-water is nearly 2,000. I think it would be seen that that if you were to take an equal mixture of sewage—take 100,000 parts of sewage containing 20, and 100,000 parts parts of salt water, you would have in the one case 2,000, and in the other 20. In the half of that, that is, in 100,000 parts, you would have 10 from the sewage, and, say, 1,990 from the sea-water; so it makes no kind of difference; so that the proportion of chlorine in the river water is practical evidence of the quantity of sea water at that point.

12,255. The greatness of the difference in the chlorine between the river water and the sea water makes it impossible that the chlorine test can go astray?—Yes, quite so; the difference between the 10 and the 20, as compared with the proportion in sea water would be very little more than the error of analysis.

12,256. Now, have you a table of the analyses of various samples of water taken between Teddington and Southend, showing the solid residue?—Yes (*producing a table*).

12,257. I see that the samples were taken at the surface and at deep water respectively, and at high water and low water?—Yes.

12,258. What does this show to your mind?—I do not know that it proves anything to my mind; it is only the solid residues of the same samples of water that were collected.

12,259. (*Mr. Bidder.*) Those are water samples and not mud samples, I believe?—They are water samples, but they are total solid residues in the same waters as were examined for chlorine, and which are described in the first and second pages.

12,260. (*Mr. Balfour Browne.*) These show, upon the 14th and 22nd of September, the residues of the very same water that you described before?—Yes.

*The same were handed in and were as follows:*

SOLID RESIDUES in Samples.

*Collected 14th September* 1882.

| | High Water. | | Low Water. | |
|---|---|---|---|---|
| | S. | D. | S. | D. |
| Teddington - - | 30· | 29· | 29·5 | 30· |
| Chiswick - - | 29·5 | 29·5 | 35·5 | 41·0 |
| St. Paul's Pier - | 460· | 485· | 33· | 32· |
| Deptford - - | 915· | 965· | 105· | 110· |
| North Woolwich - | 1380· | 1410· | 345· | 415· |
| Barking - - | 1565· | 1595· | 590· | 700· |
| Crossness - - | 1850· | 1900· | 1030· | 1100· |
| Erith - - | 2131· | 2040· | 1065· | 1100· |
| Gravesend - - | 3050· | 3165· | 2120· | 2230· |
| Southend (end of Pier) | 3940· | 3940· | 3740· | 3680· |

The figures are parts in 100·000.
The letters S and D mean that the Sample was taken near the surface or deep respectively.

SOLID RESIDUES (parts per 100·000) in Samples.

*Collected 22nd September* 1882.

| | High Water. | | Low Water. | |
|---|---|---|---|---|
| | *S. | D. | S. | D. |

* S means near surface.
D means deep.

12,261. (*Mr. Bidder.*) Combining suspension and solution?—No, they do not; they show the solid residues in the filtered water.

12,262. Then they are matters in solution only?—Yes.

12,263. Matter which becomes solid by evaporation?—Yes.

12,264. (*Mr. Balfour Browne.*) Have you also a table showing some determinations made by Professor Wanklyn's method of analysis?—I have.

12,265. That shows analyses of water taken at the same places from Teddington to Southend on the same dates?—Yes, they were taken partly upon the 14th and partly upon the 22nd of September.

*The same was handed in and was as follows:—*

DETERMINATIONS by WANKLYN'S METHOD.

Samples taken on the 14th and 22nd September.

| | Free Ammonia. | Albumenoid Ammonia. |
|---|---|---|
| | Parts per Million. | |
| Teddington - September 14, L.W. deep | ·026 | ·130 |

J. T. WAY.

12,266. (*Mr. Bidder.*) Were the samples taken by you?—No, but they have been proved.

12,267. (*Mr. Balfour Browne.*) First, taking Teddington at high water, upon the 14th of September, I see the albumenoid ammonia in parts per 1,000,000 was ·120; is that about a fair average that you would expect from river water?—That is about what it should be at Teddington before the water is filtered, that is to say, filtered by the water companies.

12,268. I see in every case that has yet caught my eye, the proportion is higher for high water than for low water?—Yes, to a certain point it is.

12,269. Take St. Paul's Pier, the proportion is ·120 for low water, and ·180 for high water?—Yes.

12,270. As you come down, I see the amount of albumenoid ammonia increases; is that so?—Yes.

12,271. Until at North Woolwich you get at low water ·2, and at high water 1·04?—That is so; that was a very peculiar sample; it stunk immensely.

(*Mr. Bidder.*) That appears to have been an abnormal sample.

(*Witness.*) I think in all probability it was taken where the flow of the river coming round from North Woolwich would carry the sewage.

(*Mr. Bidder.*) There is a sewer discharging at North Woolwich; perhaps you are not aware of that.

12,272. (*Mr. Balfour Browne.*) Leaving out that specimen, there is a gradual rise to Barking, where you get ·26 and ·24. At Crossness it is still higher, and then it begins to decrease till you get to Southend?—Yes; all I would say about that is, that it is clear the influence of the sewage is found very strongly in the middle section of the river.

12,273. It shows that in the central section of the river there is more sewage than anywhere else?—Yes, in the central section of the river from North Woolwich perhaps to Erith, and I might say that the very reason why it falls off below is that there is a great deal more sea water there. The quantity of sewage in comparison to the sea water is so much less.

12,274. I see, with regard to the sample at North Woolwich, it could scarcely be taken opposite the sewer, because it was taken at three points across the river?—That is so.

12,275. Do you believe that the reduction of the sewage by means of oxidation would be considerable in this case?—It would not be practically considerable, but, of course, it would be considerable.

12,276. But not practically considerable to abate the nuisance you have spoken of?—I was quite surprised to hear it discussed as it was discussed, because the quantity of oxygen required is so enormous to get rid of a day's sewage. The solid matter in a day's sewage is something like 400 or 500 tons of total fæces, and it is a well known rule in chemistry that non-nitrogenous matter like sugar and gum, and things of that kind, take their own weight of oxygen to consume them, and that nitrogenous matters like gelatine, albumen, creatine, and so on, take double their weight of oxygen to destroy them.

12,277. (*Mr. Bidder.*) So that it would be something between those limits?—You may take the lesser one if you like.

(*Mr. Balfour Browne.*) You would want weight for weight of oxygen.

12,278. (*Mr. Bidder.*) You would want 100 tons of oxygen?—You would require a great deal more than that.

12,279. Of course, taking the dry matter only, it would be 100 or 110?—It would be 250 tons, including the dry matter, not only the fæces but the urine as well, that is in the liquid of the sewage, but it would be matter that would have to be oxidised.

12,280. One hundred tons solid from fæces, and 150 tons of solid matter from the liquid sewage?—Yes, that would be the lowest. I do not put it as an estimate of what comes from the sewer, but of what comes from the main. I say it would require its own weight of oxygen to destroy it.

12,281. (*Professor Williamson.*) The residue of the urine, so far as it consists of urea, would not require oxygen?—No, but I am not allowing for any other things; there is a great deal more in the sewage than that.

12,282. (*Chairman.*) What would require oxygen would be 100 tons of dry matter?—Say that 100 tons of oxygen were required, put it in the mildest fashion you will.

12,283. (*Mr. Balfour Browne.*) Could that practically be brought to bear upon the oxidation of this quantity of sewage?—I cannot see that it would, because it has to be dissolved, and then a fresh quantity to be brought to it, and in point of fact if oxygen were taken from the air to destroy the whole; if it were really the fact that the whole of the organic matter in a day's sewage were destroyed by the oxygen delivered to it by the air, the air in that neighbourhood would become absolutely without oxygen.

12,284. Does the 150 tons include the urea?—It does include the urea.

12,285. (*Chairman.*) But the urea would not require oxygen?—It would not.

12,286. (*Mr. Bidder.*) The urea, as you told us, being oxidised before it gets to the river, what would be the total solid matter at the time of discharge into the river?—The urea would be converted into carbonate of ammonia.

12,287. (*Professor Williamson.*) If you wrote off urea from the total solids what difference would that

*Prof. J. T. Way, F.C.S.*

14 March 1883.

make; can you give it us roughly?—The urea of the urine is not half the solid.

12,288. It is something about approaching to it, is it not.

12,289. (*Dr. Stevenson.*) Then there is the mineral matter in the urine, which is about one-fifth?—Yes, that is a good deal. I do not wish to overrate the matter. I will put it in this way: If I take the fæces alone, and say that 100 tons of oxygen are wanted, it is an enormous quantity to be obtained to bring to the surface of the river to be changed for something else; and my belief is that if it were possible that the whole of the sewage should be burnt up day by day as it went in, the air of the neighbourhood would be irrespirable; all the oxygen would be gone.

12,290. A remarkable reduction of oxygen in the water has been shown by Dr. Tidy and Professors Heaton and Tuson. I daresay you were here when they gave their evidence as to that,—what does that show to your mind; does that show the eating up of the sewage?—It shows the eating up of the oxygen, I think; there is such an enormous amount of organic material ready to be oxidised in the sewage, that it takes it in hand immediately and uses it, but where the next lot of oxygen is to come from it is not so easy to see.

12,291. (*Mr. Bidder.*) But it does indicate *pro tanto* that the sewage is being oxidised?—Yes, it does, and it shows a disposition in the sewage to be oxidised.

Adjourned to Tuesday the 10th of April at half-past 12.

---

# House of Commons Committee Room, No. 25.

## THIRTY-FIRST DAY.

### Tuesday, 10th April 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
FRANCOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

(*Mr. Lumley Smith.*) My Lord, at the conclusion of the last day we finished the evidence-in-chief of Professor Way, and now my learned friend, if he wishes it, has an opportunity of cross-examining him.

(*Mr. Norman Bazalgette.*) We have no questions to ask Professor Way.

(*Mr. Lumley Smith.*) The next point is this. There were various samples of water taken for the purpose of analysis, and my learned friends said that they did not desire us to call all the men who took the samples, but that they wished to have the men who took the samples at three places, viz., Erith, Gravesend, and Southend. I think my learned friend is anxious to know how long they took, and I propose now to call those witnesses.

WILLIAM HICKS examined.

*W. Hicks.*

10 April 1883.

12,292. (*Mr. Lumley Smith.*) I believe you are the keeper of the hospital ship "Rhin"?—Yes.

12,293. That belongs to the Port Sanitary Authority, I believe?—Yes.

12,294. Did you, upon the 14th September, take three samples of water?—Yes.

12,295. Do you remember how you labelled them?—Yes.

12,296. How were they labelled?—"North shore," "Middle Channel," and "South shore."

12,297. I believe you handed them to Dr. Collingridge?—Yes.

12,298. Upon the 22nd September you took three samples, did you not?—Yes.

12,299. Did you take them in the same places, as nearly as you could, as before?—Yes, in the same positions as the first.

12,300. Now, having settled that they were in the same positions on both days, I will ask you what were those positions; which did you take first?—I took that upon the south shore first.

12,301. Is there anything to fix the place where you took that sample?—I took it alongside of the ship, upon the south shore.

12,302. Your ship is anchored at Gravesend, is it not?—Yes.

12,303. And you took your first sample close to your ship?—Yes.

12,304. Could you tell us at all how far it is from the shore; of course, the shore would vary at high water and at low water?—I should say the mid-channel sample would be about half a mile from each shore. The first would be taken a quarter of a mile from the shore, the next a quarter of a mile from that to the mid-channel, and the next a quarter of a mile from the other shore.

12,305. That is how you took them?—Yes.

12,306. Did you take them at high water or at low water?—I took them at low water.

12,307. And at high also?—Yes.

12,308. Then you took six samples; is that so, if you took them at high and low water?—I took two off the south shore, four in the middle, and two off the north shore, that was eight bottles.

12,309. On each day?—On each day.

12,310. You took one how deep below the surface?—22 feet below the surface.

12,311. In each position, you took one sample one foot from the surface?—Yes.

12,312. And where you could get 20 feet you took 20 feet?—Yes.

Cross-examined by Mr. NORMAN BAZALGETTE.

12,313. You have not told us at what part of the river you took these samples; were they taken at Erith, Gravesend, or Southend?—They were nearer Gravesend. I am only lying one mile below Gravesend.

12,314. What was it that determined in your mind

the exact time when high water or low water was reached when you took the samples?—According to my orders.

12,315. How did you know it was high water when you took the samples?—Because the ship swings at the ebb and swings at the flood, that is the reason why I knew it.

12,316. You determined it by the swinging of the ship?—Yes.

12,317. You say you took two off the south shore, and two off the north shore, and four in mid-channel?—Yes.

12,318. Why did you take four in mid-channel and only two at the sides?—Because I was ordered.

12,319. How long did it take you to take all those samples?—I should say 20 minutes.

12,320. What is the width of the river at Gravesend?—I should say a mile and a half.

12,321. First of all, off the south shore you took a sample from the surface, and then you took a sample 20 feet deep?—Yes.

12,322. Then you took another off the south shore and then went to the middle of the channel?—No, I went to the south side of the river, and then I went to mid-channel, and then I went to the north shore, and that finished it.

12,323. First you took a sample upon the surface, and then another 20 feet deep at the three places?—Yes.

12,324. Did it only take you 20 minutes to take all those samples?—From 20 to 30 minutes; I had not any watch to go by.

12,325. When you took your 20 feet sample, what precaution did you take to secure that the water you took represented the water at 20 feet deep?—I do not think anybody could do it better than I could.

12,326. But will you show us how you did it?—If you will give me a bottle, I could do it, I could not do it without; the stopper was pu into the bottle, and the bottle was put into a bag with a weight upon it, and the bottle was lowered to 20 feet or whatever it might be; and then, when the bottle was down there, the piece of line was hauled in, and the stopper went out of the bottle, and the bottle was filled with the water, which was at 20 feet; if I had filled the bottle before it got down, it would not have been a true sample of the water.

12,327. Then you have got a sample of water taken at 22 feet, how did you get that up?—I hauled it up. I hauled the bag back.

12,328. Did you put back the stopper before you hauled it up?—No.

12,329. (*Chairman.*) What sort of bottle was it, was it a wine bottle, a bottle with a small neck, or what?—It was a bottle with a small neck for the size, I should say.

12,330. (*Mr. Norman Bazalgette.*) At low water, did you take your samples, 20 feet deep?—Yes.

12,331. At both north shore, south shore, and mid-channel?—Yes.

12,332. Did you touch the bottom?—No, I did not touch the bottom because my ship draws 17 feet of water.

12,333. Did you take any soundings to find out what the depth of the water was at low water?—No, only that I dipped in the line that the bottle was fast to.

Re-examined by Mr. Lumley Smith.

12,334. You had a line, and you lowered that line to the bottom?—Yes.

12,335. And then you lowered the bottle and then you drew the stopper, and then you drew out the bottle with the water in it?—Yes.

12,336. (*Mr. Norman Bazalgette.*) You say that the whole operation occupied from 20 to 30 minutes?—Yes.

12,237. Do you say that from observation by your watch, or was it only a rough guess?—It was only a rough calculation.

The witness withdrew.

Walter Bound examined.

12,338. (*Mr. Lumley Smith.*) What are you?—Pier master.

12,339. At Erith?—Yes.

12,340. Did you take some samples of water at Erith?—I did.

12,341. On what days did you take them; did you take them upon the 14th September?—I did.

12,342. In how many different places did you take them?—I took them in four different places across the river.

12,343. Did you take them at high water and at low water, or only at one state of the tide?—At high water and low water too.

12,344. Could you tell us the position in the river in which you took them?—I took them in a line from the corner of the pier to the Red House on the north shore.

12,345. Could you tell us the distances at which you took them from the shore?—I could not tell you the exact distances across the river, but I divided the distance across the river as nearly as I could into equal parts.

12,346. What did you do with the samples; did you come back with each sample or bring them back together?—I had all my bottles ready in the boat, and took them as I went.

12,347. When you got the samples did you cork them?—I corked them and labelled them.

12,348. Were your bottles full?—They were full bottles.

12,349. What did you do with them?—I brought them to the pier house ready for the gentlemen to come and take them away.

12,350. How long did it take you from first to last to take the whole of the samples?—I think I might have been a little more than half-an-hour taking them right across.

12,351. And you corked them up together?—Yes.

12,352. You took some more samples upon the 30th November, did you not?—I did.

12,353. Did you do those in the same way?—You mean the small samples?

12,354. Yes?—I took some small samples off the end of the pier.

12,355. I do not think that any question arises about them, but you took some small samples off the end of the pier every day from October 10th?—Yes.

12,356. How did you get your deep samples?—I had a line fixed to a lead and a line fixed to the stopper, and I had the line marked to 20 feet, and when it was down to 20 feet, I drew the stopper, and no water could go in then in drawing it up, because the bottle was full.

Cross-examined by Mr. Norman Bazalgette.

12,357. Your observations took you a little over half-an-hour to make one set?—It might be three-quarters of an hour. I had no watch in my pocket to measure it by.

*W. Bound.*

10 April 1883.

12,358. How many samples did you take then?—took two at each place.

12,359. That was 8 samples; one set 20 feet deep and one just below the surface?—Yes.

12,360. At the 20 feet deep one did you get on to the mud?—No.

12,361. Do you know what depth you get on the north shore or upon the south shore at Erith at low water?—I do not know exactly; it is a thing I do not profess to know.

Re-examined by Mr. LUMLEY SMITH.

12,362. Did you go at low water to the same places as you did at high water, or did you divide the river in the same way?—I took the same places as near as I could.

The witness withdrew.

WILLIAM BRADLEY examined.

*W. Bradley.*

12,363. (*Mr. Lumley Smith.*) What are you?—A lighthouse keeper.

12,364. At the pier head at Southend?—Yes.

12,365. Did you take some samples of water by direction of the Port Sanitary Authority upon three days?—Yes.

12,366. On September 14th, September 22nd, and November 30th?—Yes.

12,367. Did you take the samples both at high water and at low water?—Yes, at high and low water.

12,368. Upon each occasion how many samples did you take?—I took them every half mile for two miles from the pier-head. Upon the third occasion, 30th November 1882, I only took the samples off the pier head.

12,369. At how many points across the river did you take them?—Four of them.

12,370. How far from the pier-head was the first?—Half-a-mile.

12,371. Then a mile?—Yes, then a mile and a half and two miles.

12,372. How many did you take at each place?—One 20 feet below the surface, and one one foot below the surface.

12,373. Will you just tell us how you took the deep ones?—I made the bottle fast to the lead line and lowered it down, and made the cork fast to a piece of string, and then pulled the cork out.

12,374. And then drew it up?—I let it remain two or three minutes.

12,375. Did you cork them?—Yes, after they were up.

12,376. What did you mean by letting it remain two or three minutes; do you mean before you pulled it up?—Yes.

12,377. And as soon as you got the bottles up, you corked them up and labelled them?—Yes.

12,378. How long did it take you to take each set. I believe the river is pretty wide there; did you go straight across?—I suppose it took rather more than half-an-hour.

12,379. Is that half-an-hour to go across and come back?—Half-an-hour to go there and half-an-hour back again.

12,380. It would take about an hour altogether?—Yes.

Cross-examined by Mr. NORMAN BAZALGETTE.

12,381. You say you began at the pier-head and took them at four stations till you reached two miles?—Yes.

12,382. That would be about the centre of the river?—It would be about the centre from the pier-head to the Nore Sand.

12,383. Did you take any upon the other side of the river at all?—No, not upon the other side of the river.

The witness withdrew.

*Mr. Lumley Smith* stated that he was desirous of calling one witness who was in the habit of raising wrecks.

Mr. CHARLES WOOD examined.

*Mr. C. Wood.*

12,384. (*Mr. Lumley Smith.*) You are superintendent of the wreck and mooring service of the Thames Conservancy?—Yes.

12,385. How long have you been in the service of the Thames Conservancy?—Since 1869.

12,386. Have you been during that time engaged in lifting wrecks in the River Thames?—Yes.

12,387. Previously to being in their service, had you any experience in lifting wrecks?—Yes.

12,388. For how long altogether?—For about 20 years before I was in their service.

12,389. That makes altogether between 30 and 40 years' experience in raising wrecks in the Thames?—Yes.

12,390. Have you in the course of that time found much difference in the condition of the wrecks which have been raised?—Yes.

12,391. In what respects have you found a difference?—I have found a great quantity of mud in the bed of the river.

12,392. To make a little comparison, do you remember raising a wreck in Halfway Reach about 1860 or 1861?—Yes, I do.

12,393. Whereabouts was it in Halfway Reach?—She was just by Dagenham, above where the Dagenham Docks were to be.

12,394. You raised her and put her upon the foreshore off Dagenham?—Yes, off Dagenham.

12,395. Had she been down long?—She had been down about a week.

12,396. In what condition did she come up?—She had a small trifle of mud in her, but not a great deal.

12,397. Where did you put her?—I put her upon the foreshore about half-a-mile above Dagenham Dock.

12,398. What state was the ground in there?—It was perfectly clean—a hard shingle.

12,399. Were you able to walk round her and repair her?—Yes.

12,400. Do you remember another vessel being sunk in the same spot?—Yes, as nearly as possible.

12,401. When was that?—In November last.

12,402. That would be about 20 years afterwards?—Yes.

12,403. Was she sunk about the same spot?—She had been in collision, and they ran her upon the shore, and there was nine feet of mud; the mud was up to her marks nine feet.

12,404. Was that upon the same spot as you had found the wreck in 1861?—Yes.

12,405. (*Chairman.*) What was the mud in the first vessel was it mud that got in from where she

lay, or mud that flowed into her from the water?—Mud that flowed into her from settlement.

12,406. (*Mr. Lumley Smith.*) You say that where you found a clean beach upon the first occasion you found nine feet of mud upon the second?—Yes.

12,407. What sort of mud was it?—It was rather white upon the top, but underneath it was black mud—all sewage.

(*Chairman.*) This evidence appears to relate, not so much to mud depositing inside the vessel, as to mud existing upon the bank.

12,408. (*Mr. Lumley Smith to the witness.*) That is true. Last month were you engaged to raise a couple of barges?—Yes, I was.

12,409. Where were they?—At Northfleet Hope.

12,410. Where?—One was in mid channel, and the other more to the southward.

12,411. How long had those barges been in the water?—One a week, and the other about five days.

12,412. What state did they come up in?—They had a great quantity of mud in them.

12,413. Was it more or less than in the barge that you raised in 1860 or 1861?—Yes, much more.

12,414. What sort of mud was that?—What was in the barges was loose white mud, settlement—it had not been down long enough to get like the other.

12,415. Is there much mud in Northfleet Hope?—Yes.

12,416. What sort of mud is it?—Black mud.

12,417. Is it like ordinary Thames mud or not?—No, it smells and is very black; it came up upon our chains—as we hove the chains under the wreck the chains were smothered with it.

12,418. Is that the same sort of mud as you find in Halfway Reach now?—Yes.

12,419. Do you know Gravesend Reach?—Yes, I do. *Mr. C. Wood.* 10 April 1883.

12,420. Have you found mud there in deep water?—Yes, black mud.

12,421. The same as you have been describing?—Yes.

12,422. Do you remember in bygone years when there used to be that sort of mud there?—No.

12,423. What sort of bottom used there to be?—Clay bottom in some parts, and some parts were gravel.

12,424. At any rate there was none of this black mud?—There was none of this black mud.

12,425. Do you remember the sewer outfalls being opened in 1864, and the sewage being brought down here?—Yes.

12,426. Now as to the water above Greenwich, is it better or worse than it used to be?—I think that the water is brighter, and that there is less mud above Greenwich than there used to be.

12,427. As to the water below, is that worse or better?—It is much worse.

12,428. What part of the water is worse in consequence, in your opinion, of the discharge of the sewage?—Right away from Woolwich to Sea Reach.

12,429. All that you think is worse than it was before?—Yes, much worse.

12,430. What is the worst point of all?—Gravesend Reach and Lower Hope are very bad, and at Jenning Tree Point the bottom has grown up 10 feet within the last few years.

12,431. What sort of mud is that?—All sorts: sponges and rags and guts, and all sorts of things; you might load a ship with sponges and rags down there, if you liked.

Cross-examined by Mr. Norman Bazalgette.

12,432. You have been raising vessels for the Thames Conservancy since 1869?—Yes.

12,433. Who were you raising them for before 1869?—Anybody I could get to employ me.

12,434. You say that in 1861, when you raised a vessel in Halfway Reach, there was a small quantity of mud in her which was not objectionable?—Yes.

12,435. And that last November you raised a steamer and found about nine feet of mud where before you found none?—Yes.

12,436. Did I hear you describe that mud as being clean enough upon the top, but dirty when you got inside it?—It is clean enough upon the top, but when you come to go into it, it is all black sewage.

12,437. It is not objectionable upon the surface?—It is not upon the surface.

12,438. You say that the barges you raised last month had a quantity of white mud upon them, what kind of white mud was that—clay?—No, it was ordinary white mud.

Re-examined by Mr. Lumley Smith.

12,439. There has been a great quantity of land water coming down of late years, has there not?—Yes, a great quantity.

Examined by the Commission.

12,440. (*Chairman.*) You have known the river for a long time, have you not?—I have.

12,441. I suppose you always have known mud in it that you could not walk upon?—Yes.

12,442. What is the greatest depth of natural mud that you have known the Thames produce?—There used to be mud in the Upper Pool.

12,443. What depth?—Three or four feet deep, perhaps.

12,444. Not eight or nine feet?—No.

12,445. Has that mud in the Upper Pool got washed away now?—Yes.

12,446. To what do you attribute that, to the washing of the steamers?—No; I think there has been a good deal of land water down of late years.

12,447. You think it will come again in all probability?—Yes, I daresay it will.

12,448. Was it there a year or two years ago?—No, it has been lessening for some years.

12,449. It was a different mud, you say, from this black mud you have spoken of?—Yes, it was not such a black mud.

The witness withdrew.

George Custance examined.

12,450. (*Mr. Lumley Smith.*) Were you at one time pier master at Erith?—Yes. *G. Custance.*

12,451. From when to when?—I ceased to be so in October 1881, I think.

12,452. You were pier master there till two years ago?—Yes.

12,453. How long were you there as pier master?—About 19 years.

12,454. How old are you?—I am about 65.

12,455. You know pretty well, do you not, what the river has been like at Erith?—Yes.

12,456. Will you tell me this, do you remember the outfalls being opened at Barking and Crossness?—I remember the first outfall, that was at Crossness, before Barking.

12,457. You are not quite right there I think, because Barking was opened first?—No, I say not.

12,458. Before the outfalls were opened what was

*G. Custance.*
10 April 1883.

the river like at Erith?—It was very good, it was beautiful water, clear and wholesome and healthy.

12,459. What used they to use it for?—I have known the water to be made use of at Woolwich for drinking water before I came to Erith.

12,460. Did you use it for cleaning purposes at Erith?—We used to do so before the outfalls were opened.

12,461. When you were last at Erith, what condition did you find the river in?—It was very bad.

*The Chairman* intimated that these facts were to a certain extent conceded by the other side.

12,462. (*Mr. Lumley Smith.*) Can you use the water for cleaning now?—You must take it at a certain time of the tide if you want to use it for cleaning purposes, such as cleaning yachts; the water is not fit at half ebb for cleaning decks and scouring; instead of making them white, it makes them rather dirty.

12,463. Have you had to complain of the smell of the river?—Yes, very much.

12,464. Does it affect your health and comfort?—It has affected me myself several times.

12,465. To what extent has it affected you?—It has given me great headache and diarrhœa.

12,466. Did you attribute that to the river?—I did.

12,467. Was the smell of the river at this time disagreeable when you were ill?—It was. I attributed my illness always to that.

12,468. Amongst your men have you known it to produce illness?—I have known it to produce headache and stomach-ache, and I have had medicines given to me to distribute which would be good for that.

12,469. How would that be perceptible?—In the vapour and smell that would arise from the mud. When gentlemen would come to land upon the pier, they would turn back again and say it was not fit to smell, that they could not stand it.

Cross-examined by Mr. Norman Bazalgette.

12,470. By the side of the pier at Erith one of the sewers runs out, does it not?—But that is nothing that goes out a long distance away from the pier, it was from the old garden, but it is taken about 300 or 400 feet below low water mark; that does not affect it, it is not from that at all.

12,471. Do you happen to have noticed whether that sewer is in a broken and imperfect state?—Some barge might have sat upon the pipe, perhaps.

12,472. But have you noticed that it is imperfect in its condition?—No.

12,473. You have stated that you suffered from illness from being over the river?—Yes, lots of times.

12,474. When; at what time of the year?—In the summer, many times off and on, mostly when I have been cleaning upon the pier.

12,475. Did you have to knock off work, to stay off from your work?—At times I would have, but not for weeks, only a day or so.

12,476. What has been the longest period that you had to stay away?—About two or three days.

12,477. And did you put yourself under the doctor's hands?—Yes, I have done so, but my wife used to get me some stuff to take upon sugar, or I would take some ginger brandy to ease myself; but I never staid regularly away from my work.

12,478. You say the water has not been drunk at Woolwich for many years?—It has not.

12,479. Would you tell me how long it has ceased to be drunk at Woolwich?—I could not tell you; but when I was in the Steam Reserve at Woolwich I made use of it daily.

12,480. How long ago would that be?—In 1847.

12,481. Do you happen to know the flushing reservoir at Erith where the water is admitted at high tide, and then let out with the ebb to wash away the mud?—At what part of Erith?

12,482. In the timber yards there, do you know them?—Mr. Beadel's, do you mean?

12,483. Above the pier?—There is only a coal wharf and a causeway there; there is no letting out of water there.

12,484. You do not know of any reservoirs of that description for washing away the mud?—There is one there which washes out the mud from Mr. Beadel's coal wharf.

12,485. Has that been at Erith for a good many years?—Yes.

12,486. So that there has always been a tendency for the mud to deposit there?—No, not for the mud to deposit there; but to keep the mud from accumulating from the outfall, they have had to get the reservoir made larger to wash the mud away.

12,487. But it existed before?—Yes, it existed before, but it was a small one before.

Re-examined by Mr. Lumley Smith.

12,488. It was a small one before, but they have had to make it larger?—Yes, and since they have had steamboats coming there, they have had it made larger to keep the channel clear for steamboats.

Examined by the Commission.

12,489. (*Chairman.*) There was a time, you say, when you used to drink the Thames water at Woolwich?—Yes.

12,490. You do not remember when you left off doing so, but do you remember whether it was before the outfalls were there, and did you continue up to the time of the outfalls to drink the water, or did you discontinue it before that?—Yes, before that; because the Government had means at the dockyard of supplying the ships with water.

12,491. So that you have no occasion to use it?—No.

12,492. Can you say that the water was fit for use to drink up to the time of the outfalls?—Yes, up to the time of the outfalls, but after that it was not fit for drinking purposes.

12,493. How do you know it was fit for use up to the time of the outfalls?—By drinking it.

12,494. But did you drink it?—We did drink it before the outfalls, but afterwards, when the outfalls were opened, as the Government had brought us the pure water, who would drink the dirty water?

The witness withdrew.

*Mr. Lumley Smith* stated that that concluded the case on behalf of the Corporation.

(*Chairman to Mr. Bidder.*) The merest sketch of your case is all we require.

(*Mr. Bidder.*) That is my own idea, my Lord, I had it in my mind to make that observation to the Commission that what you will probably expect from me now is not a detailed analysis of the evidence which has been given, but rather a general outline of the aspect of the case which the Metropolitan Board

of Works desire to put before the Commission, and I hope that I shall be able to do that within a very reasonable compass of time.

Now I begin naturally by turning to the Commission itself, and I see that the duty which is entrusted to your Lordship and to the other members of the Commission is "to enquire into the system under which "the drainage of the Metropolis is discharged into "the river and ascertain whether any evil effects "result therefrom, and whether any means can be "applied for remedying it;" and I suppose that that must be read and understood with reference to the surrounding circumstances. I cannot imagine, seeing that the actual discharge of the sewage of London into the River Thames is a fact, is a thing which is done with the knowledge and deliberate sanction of Parliament, I cannot imagine, I say, that this distinguished Commission is appointed for the purpose of discovering whether there is sewage in the river at that part, and it must be, I take it, that the object of the Commission is not to discover whether there are any things that a sentimentalist or a person of extremely delicate organization might consider objectionable if he happened to go into the neighbourhood; but whether there is any real or substantial grievance, whether, in point of fact, the discharge of the sewage at Barking and Crossness does cause substantial injury to health, or inconvenience to those who are resident in that district. I think you cannot shut out of consideration that which was the former condition of the river, because we know that at the time when the Metropolitan Main Drainage outfalls were sanctioned the condition of the River Thames had been, as everybody knows, growing worse and worse, and it is not to be forgotten that that which was sanctioned and has been done under the powers of the Act of 1858 was sanctioned and done for the purpose of getting rid of what had become a very intolerable state of things in the river Thames, both here and all the way down to Barking, and even below.

At that time we had abundant evidence, I am not going to trouble you with it in detail now, that at that time, not only in the upper reaches of the river, but in the lower reaches of the river, the condition of the river Thames was very bad indeed. You have had several witnesses examined here, and I cannot help saying that some of the evidence called by my learned friend, Mr. Beaumont Morice, seems to me to be very much exaggerated, and although you have had some gentlemen who have told you that at that time the river was perfectly clear in the lower part of it, and that its bed was of a sandy and clean character, yet you have had other witnesses produced by my learned friend who tell you the reverse, and who tell you that which we know to be the fact, namely, the mud of the Thames was always an offensive and unpleasant product, and that the condition of the Thames was very bad before the outfalls were created; and I say, as the first observation to be made in considering the question as regards the evil effects of the discharge of the sewage under the present system, that you cannot shut out from your minds what was the state of things that existed before that system was brought into operation, not merely up here, but specially at the part which is said to be affected by it.

Now the first objection or hostile criticism against us made by the witnesses called on behalf of the City is this. On the part of Mr. Baldwin Latham a great deal of ingenuity has been expended in endeavouring to show that the system of sewerage is entirely inadequate, arguing from what was contemplated in 1855, and arguing from the Report of that date. The argument is, the system of sewers must be inadequate because it is clear that you then only provided for a certain population, whereas the population now exceeds that provided for. I confess that seems to me entirely beside the mark, because, whether we intended to provide for 3,000,000 or 4,000,000, or any other number, the question is whether, the sewers being what they are, there are the evil effects which some people say there are. But if it is necessary to go further in answer to Mr. Baldwin Latham, you will hear from Sir Joseph Bazalgette that Mr. Baldwin Latham is entirely mistaken, and that, although he does find certain figures of population in that Report, yet, in point of fact, those calculations of the capacity of the sewers were made upon hypotheses (which have turned out to be incorrect) which were very adverse to the capacity of the sewers—that is to say, it was assumed at that time that such was the inequality of flow at different periods of the day that the sewers had, within a limited number of hours, within 6 hours, to cope with half the sewage of the whole 24 hours, and it was upon a hypothesis of that kind that the sewers were assumed to be capable of dealing with a certain population. Experience has shown that that hypothesis is not realised, but that, owing to the varying distances of the population from the outfall, which necessarily equalises the flow, the result is that, instead of having to deal with half the sewage in six hours, you have to deal with it in eight or nine hours, and that consequently the capacity of the sewers is proportionately increased, but, nevertheless, I think it is only necessary to show what is the actual capacity of the sewers.

Now another point has been made which again, I say, seems to me to be beside the mark; and I must say that I think my learned friend's scientific witnesses have been very hard put to it to support the allegation they have made, or they would not have cast about so much for irrelevant matter, but they said this, when you got this system sanctioned it was contemplated that you would deodorize the sewage, use lime or deodorize it in some other way, but you did not deodorize it, and therefore you ought not to shelter yourselves under the plea that this is a thing sanctioned by Parliament. Now I looked last night at the Act of 1858, and what do I find with regard to deodorization there? That the deodorization then contemplated was a temporary expedient until the works were completed. I have here the 23rd section of the Act of 1858, and you shall judge for yourselves; it says: "The Metropolitan Board of Works in the "meantime, and until the works required by this "Act for the purification of the river Thames are "completed, may do all such works and apply all "such means as they may deem proper for deodorizing "such sewage, or otherwise protecting the public "health from any injurious consequences therefrom, "and may defray the expenses," and so on; and then the next clause goes on to say, "The said Metro-"politan Board shall cause all works to be executed "under this Act to be constructed and kept so as "not to be a nuisance, and shall, in deodorizing any "sewage, and in disposing of any sewage or refuse "from sewers, act in such manner as not to create a "nuisance." Clearly, therefore, upon the face of the Act, as I venture to think, that deodorization was a temporary expedient. Again, I say, that is a matter beside the mark because, whether deodorization was or was not contemplated at that time, you have again to take the thing as it is, and see whether that is a nuisance. Sir Joseph Bazalgette will tell you that upon certain occasions deodorization was tried for certain purposes, and it was abandoned, because, in point of fact, deodorization was a greater nuisance by far than the sewage.

(*Sir John Coode.*) Was that so since the completion of the system?

(*Mr. Bidder.*) I find I have misled the Commission; it was not that it was tried at Barking and Crossness, but that it was tried at Leicester, and experience there showed that the large quantities of matter to be dealt with created a greater nuisance than the sewage itself; and when it was seen that in the case of London the quantities would be still greater, it was out of the question. I apologise for misunderstanding, and therefore misrepresenting, Sir Joseph Bazalgette; it was not tried at Crossness.

Now, putting aside those which I venture to say are irrelevant charges, and coming to the system as it was sanctioned and as it was carried out, I wish to make this further observation—I have already reminded you of the then condition of the river. There is another very simple "platitude," perhaps, if you please, which

10 April 1883.

existed in 1858, and exists now, and that is this—you had as a great fact the sewage of London, you could not annihilate that sewage, you had to do something with it, and I think I am entitled to speak of the experience of 1858, and of the present time, that no known method of deodorization or of sewage irrigation could be applied to the sewage of such a gigantic population as that of London; and consequently you had to discharge that sewage into water, the Thames or the sea; somewhere. It is a fact that you cannot escape from, and the particular places which were selected, Barking and Crossness, were selected, after long consideration, after great discussion, after the opinions of many eminent engineers had been given upon them, as being the spots most favourably situated, for many reasons, within any reasonable distance of London. In point of fact, just as one finds, in cases of objectionable manufactures, tanneries, and chemical and other manufactories, that they resort to places which are, as it were, allocated to purposes of that kind, so it was done in the case of Barking and Crossness; you have there a length of something like five or six miles of river, which are, I may say, dedicated to stinks, where there is no house or residential property of any kind whatever along the margin of the river, but which is exclusively occupied by various kinds of manufactories of the most offensive character, all of them producing divers very offensive, and, as I should say, injurious smells. You have artificial manure works; you have guano works and you have candle works; and when you go, as some of the Commissioners have done, and, as I hope, your Lordship will do, down that part of the river, you will have a selection of horrible smells such as perhaps you have not encountered for many years past, and, beyond doubt, that is one reason why those two places were selected. It has been pointed out, and is a fact, that further up the river it is one continuous population; but you cannot go lower down, until you get beyond Gravesend, to find any place that is comparable to that for its freedom from any possibility of being injuriously affected, and its suitability for businesses of an offensive and unpleasant character. I cannot help thinking that that must be borne in mind, because I can well understand that your Lordship might hold that that which was regarded as a nuisance in Belgravia would not be held to be a nuisance in Bermondsey. There no doubt may be times when people who choose to lay their boats within a short distance of the outfall may smell an unsavoury smell; all that has to be weighed in consideration with the fact that the neighbourhood is one specially selected for that very reason. I am not coming here upon the part of the Metropolitan Board of Works to suggest to the Commission that the sewage of three and a half millions of people is put into the Thames at these two parts, and produces no perceptible effects whatever. I suppose nobody ever expected that such a thing could happen, that 26,000,000 cubic feet of sewage could be poured into the river every day and leave no sign of its presence. Parliament must have contemplated that there would be certain signs and effects locally produced by the inpouring of the sewage, but surely it is not that which you are appointed to discover, and what I venture to describe as the point in this case is the distinction between the immediate and local effect of pouring in the sewage and the general riverine effects. I think the two things should be distinguished. I admit that when the sewage is being discharged from the Barking or Crossness outfall, if you take a boat and go within 50 or 60 yards of this great volume of sewage which is pouring out, you will smell a very unsavoury smell, and see a very unsavoury sight, and for a distance of a quarter of a mile down the river you will be able to see a distinctly marked black line showing the boundary between the sewage flow and the general water of the Thames; that is what I speak of as the local and immediate effect of the inpouring of the sewage, that is, an effect which must have been contemplated, and which must necessarily follow wherever you put it. If you went 15 miles below Gravesend, if you went to Southend, if you went to the sea, it is an effect which would equally be caused wherever you discharged; you cannot go anywhere where, by some magical transformation, the instant the sewage gets into the water or the sea, it shall be instantaneously annihilated, it is a process of time anywhere, and wherever you pour into the river or the sea the sewage, you must have at that spot signs of its presence, both to the sight and the smell; it must be perceptible for a time. But while I admit that such indications must and do follow in the case of the outfalls at Crossness and Barking, I say, as regards the general effect upon the Thames, the suggestion that its pollution is dangerous and deleterious to the health of the riverine districts is entirely unfounded; and when I come carefully to analyse the evidence, I shall show that it is entirely contrary to the fact. I cannot help reminding the Commission of this, that although you are by no means bound by what has been done before, yet already this matter has been threshed out twice over and very carefully; for first, as far back as the year 1869, the people of Barking made complaints, and Mr. Rawlinson was sent down to inquire, and your Lordship may remember that, having inquired and taken a vast amount of evidence, he came to certain conclusions, one of which perhaps will be sufficient if I mention, that "the memorialists "are not in a position to establish deterioration of "health by emanation from the Metropolitan main "sewerage outfall works, as the town of Barking is "without local government powers and contains many "cesspools and much sewage-polluted subsoil."

(*Chairman.*) I think we have had a witness from Barking to show a nuisance there.

(*Mr. Bidder.*) No; with the exception of a policeman whose beat lies along the margin of the river, and who sees the line of the sewage upon the river when the tide is flowing down, there is nobody from the neighbourhood of Barking. Then I must remind you of the inquiry of 1879. I know what will be said upon the other side. They will say, "that is at the "instance of the Conservators of the Thames, and is "simply directed to the fact whether you were "obstructing the navigation; it by no means follows "that because the arbitrators upon that inquiry found "as they did, and unanimously, that there was no case "made out, you are not thereby tainting and polluting "the water." Of course I conceive that, but you will see what a large bearing that had upon this inquiry, how large a portion of the ground now covered was covered upon that inquiry; because you have had before you a great number of witnesses, and the only witnesses who attempt to prove the fact of nuisance are those called by my learned friend Mr. Morice, viz., people in the neighbourhood of Erith. The sum and substance of their evidence is that Erith was once a beautiful bay with a bright sandy shore, and now, since your outfall, it is a nasty black fœtid shore with a continually increasing amount of fœtid mud, which is very injurious to the health of the town of Erith, and which is all sewage, which, in fact, is so identified with sewage that they do not call it mud, but call it sewage. Exactly the same case was made, as a matter of fact, by the Thames Conservators; they did not fight their battle upon that part of the field, but they took the banks which were more immediately in the neighbourhood of the outfall; they took the Crossness bank; they took the bank which is opposite the Barking outfall at Margaretness, and another two banks, and said the same thing. "Those banks never were there till your outfall was "opened, and they have grown foot by foot, the mud "of which is *post hoc*, and therefore *propter hoc*, "distinctly traceable to your sewage works." We met them there, and our answer to them now is exactly the same as it was in the case of the banks. Just as in that case, we proved to absolute demonstration that the causes of those banks were the works of the Conservators and others interested in the channel, and not the operation of the Board; and not only that, but we also took the mud of that which they called

the sewage, and we showed conclusively by actual analysis that it differed in no way from the ordinary Thames mud to be found everywhere up and down the River Thames; so we shall meet them here. Your Lordship will see, therefore, that I am justified in saying how large a portion of the ground is covered by that inquiry. But I pass from that for the present, because I shall have a word or two to say about it immediately.

But while I admit, as I said a few minutes ago, the local and immediate effect of the sewage, I think this will come out, and I think it will surprise your Lordship, after all you have heard, especially when you have gone to see it for yourself, how rapidly the perceptible presence of the sewage is lost; it certainly struck myself, and I think it has struck everybody who has seen it belching out of these great sewer outfalls, as a nasty offensive stream which you trace keeping itself distinct by a black line from the rest of the river which flows with the tide,—I say it is remarkable how rapidly, after a few hundred yards, it fans out and disappears to the sight, and disappears to any ordinary sense from the general body of the river. That, of course, is a mere matter of general observation, but, beyond that, it will be the case of the Board to show you that that which seems to be true according to the eye and the nose is true also according to the analysis of the chemist, and true also according to the analysis of the microscopist, and true also in every way in which you can test it. The Erith people gave you a certain amount of evidence which, without analysing it in detail now, I think I can roughly classify under three heads; they said there were no fish; there used to be fish, such as whitebait, and now they are all gone, driven down the river; that is the effect of the poison of the sewage; and they said there were these large accumulations of fœtid mud, and that there were certain occasions upon which the water smelt offensively.

Now what is the answer of the Metropolitan Board of Works: first, about the fish; you will remember I conceded the fact that the fish to a great extent had disappeared, that where the fish had been plentiful in the neighbourhood of the outfalls they were rare; and then his Lordship suggested that I admitted the poisoning, while I repudiated the poisoning; and you seemed to think there was a sort of paradox in it. The answer is a very simple one,—the fish have disappeared, and disappeared in consequence of the sewage, but not because they are poisoned by sewage, but because the sewage in its oxidation has consumed the oxygen which they require for their life; and the very fact of the fish disappearing, while there is evidence that there is sewage in the river, and that it is being burnt up, is evidence also that there is oxygen in the river doing its work in burning up that sewage. And you have only to take the analysis of Dr. Tidy to show you one of the most pregnant facts of the case. As his figures show, the water which comes over Teddington Weir charged with its normal quantity of oxygen, a little less than two cubic inches to the gallon, as it gets down and approaches the outfalls, appears gradually to part with some of its oxygen, and when it gets into the neighbourhood of the outfalls in the neighbourhood of Erith it parts with the greater part of its oxygen, in fact, three fourths of its oxygen is gone. So that, whereas perhaps you have two inches of oxygen at Teddington Weir, when the water has flowed past Crossness and Barking, and has received its contribution of the sewage of the day, it arrives at Erith with more than three parts of its oxygen gone. It is perfectly intelligible why an air-breathing animal which depends upon the oxygen of the water for its life no longer affects that part of the river, nor can do so; but that very fact shows you that the river is doing its work in destroying the sewage, because the work of the destruction of the sewage is not this: it is not that the river is a mere scavenger to remove the sewage to a place where it will not be offensive, but it is more, it is burning it up by the oxygen of the water, so that that very fact of the driving down of the fish is a consequence and a necessary consequence and an indication of what is taking place in the Thames with regard to the destruction of the sewage. And beyond that, it being evident by the analyses of the chemists that that destruction is going on, the question follows: Is the river adequate to the work of destruction? The diminution of oxygen shows that the sewage is eating up the oxygen of the river. Is there evidence to show that there is oxygen enough to destroy the sewage? I shall show conclusively that there is.

But again, in order to keep my observations upon some system, let me now say a word or two about the other charges of the Erith people. I will refer to the mud question. Our answer is precisely the same to the Erith gentlemen as it was in the case of the other banks; an answer which amounted to demonstration there, and will here. First of all, the question whether in any part of the river mud deposits is a question purely of the set and the velocity of the water and the eddies and streams in that neighbourhood; you may put what you like into the River Thames, or any other place: sewage, pure sand, or pure silt; if you have a current running straight through it for three or four miles, of course you will not get a deposit; but if you alter the current of your river so that that which formerly received the scour of the current becomes a sort of lie-by or eddy, then you get stagnant water, and whatever there is in the river will be the thing that will be deposited. So that your Lordship sees, if I make myself clear, that the fact of the deposit has nothing to do with whether it is sewage or sand in the river. The fact of the deposit depends upon the flow of the currents; that which is in the river will deposit, or not, according to those conditions.

Now what is the cause of these deposits? Why, simply, that as in the previous case we showed what it was, so here, that, during or preceding the period of this deposit certain dredging operations have been taking place on the other side of the river which have improved it and deepened it, so that the main traffic of the river has been drawn the other side, and left this as stagnant water. Consequently, you have Erith left in a sort of eddy, and you have deposit begun and going on; and the sections, I think, will satisfy you that, in point of fact, the river has not been diminished, but the reverse, that the river channel is larger and better than before.

But that is not all my answer to the question. I say, I take the mud which you are pleased to call sewage, and to say it is black and nasty, but I take the mud and show you that, except in cases where it has come out of your own sewers, it is not different from the Thames mud all up and down the river. I take the mud and analyse it, and satisfy you that it has exactly the same constitution as Thames mud whether you take it up or below; whether you take it up at Westminster or down at Sea Reach. And not only that; I show you that, not only chemically, but microscopically, and I venture to say that I shall prove to demonstration to you, before I have done, that that mud is nothing more than ordinary Thames mud, and that, if you are to accept that mud as the produce of our outfalls, you have to account for a quantity of mud in the Thames which is 50 or 60 times the quantity of solid matter which ever came out of the outfalls since they have been constructed.

Now I do not deny that there may be a few occasions in a very hot summer when in the immediate neighbourhood of the outfalls you may perceive a certain odour from the water. I say this is very rare, and that when it does occur it is extremely local; and I think you will find, when I come to analyse the evidence of the witnesses, that with one or two exceptions they were gentlemen who were prepared to say anything. Now my learned friend, Mr. Morice, looks up. Remember that one of his fishermen, the oldest inhabitant of Greenwich, told us how the evidence was got up. A gentleman invited them to the "Golden Anchor," supplied them with pots of

10 April 1883.

porter, and asked them whether they could give evidence against the sewage.

(*Mr. Morice.*) The evidence was got up as evidence is always got up, by getting the people together.

(*Mr. Bidder.*) I am going to read the evidence if it is desired.

(*Chairman.*) Is it worth while going into this?

(*Mr. Bidder.*) You have had it before you, and I say that, when gentlemen are got together like that, they may be expected to be prepared to amplify their recollection; but the actual perception of odour, I venture to say is confined to the reaches between Barking and Crossness and up to Jenningtree Point, and that only on certain days and in hot weather. There is a gentleman, Mr. Beadle, residing at Erith, who gives evidence that he and his men, working upon the Erith mud, found a very offensive smell there; that is quite possible, and the cause of it is very apparent, because, as it is admitted now, and you will hear more about it hereafter, Erith itself pours its own sewage, not into the river as we do, but on to that mud bank, where it lies festering in the sun; so it is hardly to be wondered at that a smell arises.

(*Chairman.*) That is what you say, that it is not to be wondered at that Erith sewage makes a smell, and that your sewage, which is 500 times as much, makes 500 times as much smell.

(*Mr. Bidder.*) But our sewage though it may be 500 times as great, is treated under entirely different conditions. In the first place, a great portion of the decomposition has gone on in the sewer itself; in the second place, we discharge the sewage at high water and into the body of the river, we do not let it trickle out at all times on to the dry mud to ferment upon the mud; the conditions are entirely different, as in that case they present a large amount of nastiness to the sun and to the senses. But I should draw this distinction, that in discussing the scientific evidence you must not disregard the undoubted fact of other and not unimportant sources of pollution in the Thames, especially when you are considering evidence which is given you to lead you to believe that the Metropolitan drainage materially affects the condition of the river above it. There is evidence showing a certain amount of pollution in certain reaches of the river above Barking and Crossness, but it is practically admitted that there are very important sources of pollution other than those of the Metropolitan Board of Works. As one passes up the river, there is the Beckton gasworks; then I come to North Woolwich, a place where a great deal has been said about offensiveness, all we know of that is that there is a sewer discharging into the river which deals with the immediate district. Then we come to the River Lea. There we have the sewage of all West Ham, of 150,000 or 200,000 people, discharged into that river, and the sewage of Stratford; and we have the report of the Commissioner sent down to enquire into that river, who describes the dreadful state of things there. Then we are told that all along in Bermondsey and Rotherhithe there are a number of sewers not yet shut up, and we know that there is a very large floating population. Therefore, whilst I am far from saying that the Metropolitan sewers do not to any extent affect the river above Barking, yet I say you cannot charge us with all the pollution existing in the upper part of the river, for there are sources of pollution, and very important sources of pollution too, which exist in the upper part of the river.

But now, my Lord, I have this pregnant observation to make. There is not a particle of evidence brought before you to show that, as a consequence of our sewage works, there is any low state of health in the districts in the neighbourhood of the outfalls, or along by the river. On the contrary, they are obliged to admit that these are particularly healthy places, that Erith, which for instance has taken such a prominent part in this enquiry, is a place where the general death rate is low, and not only is the general death rate low there, but the death rate from zymotic diseases, which is the class of diseases more directly connectible with such deleterious influences as these are suggested to be, is remarkably low. And moreover, all the witnesses who have been called before you to describe the state of the river are men of remarkable robustness and healthy appearance, and I shall be able to carry that further and show that these districts are remarkably healthy. It is almost shown, I think, by the witnesses who were called. Dr. Corfield could only in one or two cases show any cases of zymotic disease above the average of London, and then it was shown that they were more than accounted for by the peculiar character of the population as compared with the population of Western London. But we shall follow out this into particular districts, showing in what part of the river these diseases occur, and you will find that the river-side parts are remarkably free from those diseases which might be said or thought to be connected with river pollution.

Now, before I pass from that let me remind you that the populations which are more immediately upon the river, for instance, the boys in these training ships anchored in the very sewage flow (and if anybody, if there were deleterious influences, could suffer from them, surely it is those boys), although there have been one or two outbreaks, yet their general health has been exceptionally good, and they continue there to this present day, and the outbreaks which by one or two persons were supposed to be possibly connected with the river were connected with other things, such as trichinosis from eating measled pork. Surely it is a very important fact, when we are talking about the health or injuriousness of the river, when we find what happens with 200 or 300 boys who have been moored there for years and are moored there still. Also the Small Pox Hospital, which has been moored down in a lower section of the river, has been found to be in so salubrious a spot that it has been retained there. Upon the whole, I venture to say there has been no indication of any injury to the riverine or riverside health from the pollution of the Thames, but the contrary.

Now, when I come to turn to the scientific evidence, I shall have a good deal of scientific evidence to put before you, and I will endeavour to show shortly the nature of the evidence which the Metropolitan Board of Works intend to put before you in answer to the evidence on the other side. You have had the evidence of engineers, and you have had the evidence of chemists, and one thing has struck me. I do not know whether it has struck you, viz., the marvellous timidity of the scientific men in venturing to any conclusion; they have put before you masses of figures and wildernesses of tables, but they do not venture themselves. I say it after listening to it very carefully,—to draw the conclusions which their own clients wish them to draw.

Now let me first deal with the evidence of the engineers; they have put before you a lot of hypothetical figures. Shortly, I may condense their evidence as bearing upon the question thus. The proposition they want to establish is that there are always a number of days', say 30 or 40 days', sewage in the River Thames, and that argument is of this kind. We have from analyses by chemists at different parts of the river the amount of chlorine in the water; the amount of chlorine in water, whether it be fresh water or sewage, is relatively so small as compared with sea water that you may call it "nil." For the purpose of comparison, the amount in sea water being very large, being something like 1,960 parts in 100,000, I do not object to that reasoning so far. At any point of the river, given an analysis, you may say the water there is so many parts sea water and so many parts fresh water. I do not object to that; but they go further and they say, What about the fresh water? They go to the Returns of the Metropolitan Board of Works, and say that on such and such a day you discharged so many cubic feet of sewage into the river; on the same day there were so many million

cubic feet of upland water coming into the river from Teddington and other places, and consequently we at once assume that the proportion of the fresh water which is sewage is that proportion—it may be one-eighth or it may be one-tenth. Thereupon, applying that over the whole river, they say that at Gravesend, or at other places, the chlorine tells us that, say, 20 per cent. is fresh water; the gauging tells us one-tenth of that is sewage and the rest is upland water; consequently we tell you that 2 per cent. of the whole river at that point is sewage. So we work out the calculation, and tell you that there are so many days' sewage between Crossness and Erith, and so many days' sewage between Erith and Southend.

Now I will show you two radical answers which make that calculation totally worthless; it is based upon the assumption, which everybody knows to be contrary to fact, that once sewage, always sewage,—that the sewage, being poured in at Barking in the proportion say of 1 to 10, and that sewage oscillating backwards and forwards, though it may be 20 days hence at Gravesend or Southend, they still label it sewage, though everybody has said, and Dr. Tidy has admitted (the question of rate being matter of discussion), that, as a matter of fact, the sewage is burnt up and decomposed, and ceases to be sewage just as literally as, if your Lordship put that envelope into the fire, it would cease to be paper.

(*Chairman.*) Would that destroy the chlorine?

(*Mr. Bidder.*) No, it would destroy the sewage. I admit the chlorine argument, that, if you find a certain number of grains of chlorine at a certain time and place, you can say with a certain accuracy that that indicates a certain proportion of sewage or fresh and sea water.

(*Chairman.*) I think what you mean is that it may show what is or had been sewage, but it does not show that it is then existing sewage.

(*Mr. Bidder.*) Exactly so, my Lord, it is just that step that is fallacious. All you can say is that a certain portion of that is liquid which once was sewage, and you can say that of every drop of rain water, I suppose, that comes from the heavens.

(*Chairman.*) Your argument is something like this, if I understand it,—that if you were to put into a bucket containing nine parts of pure water, with the ordinary quantity of oxygen in it, a tenth part of sewage, so as to make 10 parts, and you shook them all up,—that at the end of 24 hours a tenth part of that mixture would not be sewage.

(*Mr. Bidder.*) That is what I say, and what men, much more competent to form an opinion upon the subject, say is beyond dispute.

(*Chairman.*) I do not think there would be much dispute about it.

(*Mr. Bidder.*) But the engineers deal with it as a simple arithmetical problem, and ignore absolutely the chemical aspect of the question.

My second observation is of another character, that when you go to the lower end of the river, which it is convenient to take (of course there is no line between where it ceases to be river and becomes sea, but Southend Pier would be a convenient point to take), it is a convenient fact to remember that, in round numbers, taking the tidal part of the river above Southend, there is just twice as much water in it at high water as there is at low water—that is to say, every 12 hours one half of all the water that was above Southend Pier has gone to sea, and that there comes back again an equivalent quantity of water upon the next tide. And although there is that immense quantity of water swept past Southend to join the sea, yet they make this astounding assumption that there is no admixture with the sea, that it is labelled and ticketed as it goes out, and is regarded as coming back without any admixture with the sea. You will find that they actually assume that in every tide there goes to sea from Southend five days' sewage of London, which five days' sewage of London comes back just as safely as if it had been bottled up and labelled, and brought back free from any admixture with the general sea. It is ridiculous.

I now pass from the evidence of the engineers, and come to the evidence of the chemists. Now I say they do not venture to assert. When I have to refer to the evidence hereafter, I shall show you how carefully they avoid asserting that the condition of the Thames is dangerous, but they give certain figures and they say, here is evidence of a great pollution. I am not here to assume that the Thames water, after it has received the sewage, is as pure as it was before it received the sewage. I say the question is one of degree,—and whilst I admit that there is pollution, I shall, I trust, satisfy you that that pollution is not of so serious an extent as to interfere with the comfort of those who are interested in the question. I think I may put aside the very sensational statements which have been made, which might have gone down with a jury, but which were hardly worth while advancing to a body like the Commissioners; such as that there are 100 tons of sewage matter (with the great emphasis on the "tons") put into the Thames every 24 hours; because I could make a similar statement. I took the trouble to see what that 100 tons meant in another way. I found it amounted to the 20th part of a grain in each gallon of water—about as much as you could balance carefully upon a moderate-sized pen—that is about an equally valuable statement. But I will come to questions which are more important. They admit, that partially at any rate, the process of burning up the sewage and destroying it is undoubtedly going on. Dr. Tidy admits it, and Dr. Frankland admits it, though not to the same degree. Professor Way admits it, and he says the fate of the sewage is to go up sometimes to sink and sometimes to rise, and to evolve gases until it is destroyed, which is another way of saying the same thing as I and my witnesses say.

Now, that is really practically the very centre and core of the answer of the Metropolitan Board of Works. True it is that we put this large body of sewage into the river, but what happens when it goes into the river is not that it remains in the river as a polluting mass, but that it is put into such an enormous quantity of water that there is abundant opportunity for the operation to go on which is now perfectly well recognized and is seen in various rivers; that decomposition and burning up of the sewage goes on, and, before a very long interval has elapsed, it is entirely burnt up and destroyed as sewage. I cannot do better than put before you the words of Dr. Tidy, who has studied the question for years, who has maintained here the position he has always maintained, and, as I ventured to think, with very good reason, and who has summed it up concisely in these words: "If you put sewage "into pure running water in the proportion of 1 part "to 20, and let that go on for a run of 10, or 12, or 14 "miles, that sewage is absolutely destroyed"—that is Dr. Tidy's evidence—that is the result of years' experiments by Dr. Tidy and others who think with him. Just let me read what I read to Dr. Tidy in his own words: "Given then a fairly rapid river that "has received sewage in quantity not exceeding, say, "one-twentieth part of its volume, is there evidence "to prove that after the run of a few miles the water "of that river will regain its purity and become" (not merely not injurious to people who live upon the banks) "wholesome and good for drinking. To this "question I answer unhesitatingly, there is undoubted "evidence of such purification, and the evidence I "have adduced has been of a fourfold nature, physical, "chemical, medical, and statistical." That is a summary of a long argument and a summary of statistical observations in various places. Dr. Tidy has shown, by carefully carried out experiments in his laboratory, that it is so, and he has demonstrated that in nature it is so. Now, what is the fact here? We do not put in sewage in the proportion of 1 to 20—it is less than 1 to 200—it is 1 in 215; but it is said, "You must not assume because that proposi "tion is true, that, therefore, your sewage vanishes "in that way." Why not? "Because you do not "put it into pure water—you put it into water that "is already pollute and has not got that purifying

10 April 1884.

"power that I assume in the case of a pure river." There, again, it is only a question of degree. Although it is not unpolluted water, yet it differs from it in a very small degree, as I will show when I come to speak of the analysis, and that, allowing for all that difference, there is an enormous margin.

Now I turn from theory to fact, to see how it supports my view. I take the analysis which we have taken for the purpose, indeed I intend to take Dr. Tidy's own analysis of the river, and the other which has been put in, and what do I find? That, whether I test it by the albumenoid ammonia, which some chemists consider a valuable test of sewage contamination, or whether I test it by the amount of oxygen which is required to burn up the oxidisable matter in the water, which is also very valuable, and, as many chemists consider, if properly applied, a crucial test, or, in whatever way I test it, I come to this broad result, which you will find is borne out by Dr. Tidy's analyses. I begin at Teddington, with water pouring over it, which is treated here as pure water—at any rate, it is sufficiently pure to be that which is drunk by a large part of London—and let me remind you of a remarkable fact as the best example I can give you of the truth of the proposition I am enunciating, that the Teddington water is water which has received the sewage of a million of people. It is not perfectly pure water, but has a certain amount of pollution; and there is a certain amount of increase, I do not dispute it, until you come further down—until you come to the Barking outfall; the pollution between there and Teddington Weir has increased between two and three times. I do not mean taking a sample of the sewage flow as it comes out of the sewer or in the black line of the sewage, but I am speaking of the general river, and I say you will find that, whereas the general pollution of the water at Teddington is as one, and at Barking is as two and a half—at Erith it begins to fall—at Purfleet it has fallen very much, and by the time you get to Gravesend it is reduced to the purity of Teddington again. That is a fact which analysis will bring distinctly before you, the effect produced in the river by this mass of pollution—so extraordinary a mass of pollution that its extent, as compared with the water at Teddington, is about $2\frac{1}{2}$ or something under 3 to 1; yet, by the time it has got to Gravesend, all trace of that sewage has vanished, and the river is again as pure as it was when it came over Teddington; of that I shall be able to satisfy you demonstrably.

(*Mr. Abernethy.*) Dr. Tidy's answer was applying to a river flowing continually in one direction.

(*Mr. Bidder.*) I am very much obliged to Mr. Abernethy for reminding me of that. I vainly endeavoured to elicit what the magic of flowing in one direction was, because, of course, it is the motion and the mixture that are the advantage of the flowing over stagnation; but flowing in one direction is no better than flowing in another, except that one knows, in order to stir up things thoroughly, after stirring in one direction, one is apt to get a better mixture by stirring in the opposite direction. But I say, here is the fact you may tell me my theory is wrong if you please, but I fall back upon the facts, and I say the analyses show that, although the effect of my sewer is that there is an increase from 1 to $2\frac{1}{2}$, yet, as you get further down, that disappears altogether.

Now it is very interesting to trace out the line of thought which was indicated by Professor Way. Simultaneously with that operation, the result of which I have described, we find, as Dr. Tidy has shown us, a diminution in the oxygen, so that where there was, as I said, nearly two inches above, it has fallen to only half an inch of oxygen in the gallon below. But that is not all you find, because you find this very interesting fact that is brought out by that analysis, that an ebb tide which has received its charge of sewage at Barking and Crossness arrives at Erith and Purfleet, as one might say, almost exhausted of its oxygen, and it comes back a few hours afterwards from the direction of the sea re-charged with oxygen; and there is that operation going on every tide, the oxygen being consumed by each charge of sewage, and the water going out and coming back re-charged, ready for another charge of sewage. Says Professor Way, it would want 100 tons of oxygen to burn it up. Now we have taken the trouble to calculate how much oxygen is brought up every tide, and we find it is more than 100 tons, it is 200 or 300 tons. No doubt, Professor Way is right in saying that to burn up this sewage would require 100 tons or more of oxygen; it is easily demonstrable from the difference between the quantity at ebb and flow of the tide that a quantity equal to between 200 and 300 tons of oxygen is introduced with each flow of the tide.

Now, another thing is this, that if the river were not equal to its work it should have got worse, but it does not get worse, and I shall prove to you that the analysis shows the condition of the river to be as good now, at all events, to be no worse than it was years ago. If it were true that the river could not deal with the sewage, but that a part of it fell undecomposed, and was constantly accumulating on the banks and in the bed of the river, there ought to be a deterioration; but there is not, and that I shall show demonstrably from analysis. Other causes I shall show you in passing, but evidence will be given by witnesses, who will bring it out more distinctly than I can now do, that it is not a mere question of the oxygen in the water, which is the purifying agent, but there is a cause which has been overlooked upon the other side, and which our researches show is a very important one. An enormous quantity of this sewage is consumed by minute organisms of animals which feed upon it, so that it is their meat, and it ceases to be sewage. A great deal is disposed of by animalculæ; then again there are, no doubt, a quantity of algæ and minute plants of low organization which produce oxygen in the water. All that I leave to be described to you by scientific witnesses; but I cannot forbear noting one branch of evidence, and that a very important branch of evidence. You had some evidence from Dr. Tidy and Dr. Lionel Beale of a microscopic character, but I will take Dr. Tidy's evidence; he says, "I took specimens of mud and "stirred them up in a glass, and after a certain sub-"sidence I got a flocculent film at the top of the "subsiding matter, which I took out with a pipette." Then he described what he found from having examined it microscopically, Dr. Tidy admits that those are qualitative and not quantitative; he says, "I admit "that I can detect particles which are of sewage "origin, but they do not in any way indicate that "there is 10 per cent., 5 per cent., or 1 per cent., or "one part in 100,000." Now, I shall show you, by very careful miscroscopical researches of a character, I venture to say, almost unprecedented, that we have been able to go a great deal further than that; that we have been able, both as regards the mud and as regards the suspended matter of the river, to trace the matter both quantitatively and qualitatively. We shall be able to show that the quantity of that sewage matter is so small compared to the general mud of the river as to be quite inappreciable.

I think you will understand that the case we have to present to you is that that which is true in other cases is true here,—that the principle Dr. Tidy lays down applies here, and that the analyses of the other side and our own analyses concur in this, that that operation does go on, and go on effectively, and that the river is more than sufficient for the work; that that pollution which arises between Teddington and Barking disappears before you get to the sea entirely and absolutely. We shall confirm that by microscopic analyses of the mud and of the river, and I think you will be constrained to come to the conclusion that, whilst of course nobody in his senses would pretend that, if you put in the sewage of 4,000,000 people, you will not be able to smell it, yet that there is substantially no deleterious or injurious effect produced by it, and that it would be a monstrous thing that the Metropolis should be saddled with an

expenditure of millions of money in order to get rid of a local nuisance, which would not be to transfer it to another part of the river, for it would be impossible to find a more abandoned place, or a place more utterly and unrestrictedly useful for such purposes, as those for which the present site is now used. 10 April 1883

Adjourned to to-morrow at 8, Richmond Terrace, at half past 12 o'clock.

# No. 8, Richmond Terrace, Whitehall.

## THIRTY-SECOND DAY.

### Wednesday, 11th April 1883.

PRESENT:

The Right Hon. LORD BRAMWELL, F.R.S., in the Chair.

Sir John Coode, Mem. Inst., C.E.
Colonel C. B. Ewart, C.B., R.E.
François de Chaumont, Esq., M.D., F.R.S.
James Abernethy, Esq., F.R.S.E., Mem. Inst. C.E.
Wm. Pole, Esq., F.R.S., *Secretary*.

Sir Joseph William Bazalgette, C.B., called again and further examined.

*Sir J. W. Bazalgette, C.B.*

11 April 1883.

12,494. (*Mr. Norman Bazalgette.*) Before I go to your proof I believe you have a table of the areas at the present time draining to the Main Drainage sewers which you are anxious to put in?—I have. The areas which were drained had not been computed up to a recent date when I gave my evidence in the first instance; and I have since had the additional areas which have been drained added to them and brought up to the present time, they are contained in that table with some particulars both as to areas within the Metropolis and those which are outside the Metropolis. I do not know whether I need go through the figures in detail, but I can state generally that they show upon the north side that the area drained at the present time is 48½ square miles. Outside the Metropolis, Kilburn and South Hornsey add 1·71 square miles, and Hornsey equal to 1·75 square miles, making a total of 51·96 square miles, say 52 square miles upon the north side, Then upon the south side the area drained within the Metropolis is 51·21 square miles, outside the Metropolis Norwood adds ·54 square miles and Beckenham an area equivalent to ·03 square miles, taking the sewage of 5,000 people; making in all 51·78 square miles now draining into the system upon the south side. That leaves 16·57 square miles undrained, of which half a square mile consists of commons, parks, and water.

12,495. (*Chairman.*) Are you on the north side now?—No, upon the south side; 3½ square miles consist of marsh lands, and 2¼ square miles drain away from the Metropolis towards the River Cray, making a deduction from that 16½ square miles of 6·15, leaving 10·42 square miles not drained into intercepting sewers. Now those consist mainly of either agricultural land or of nursery gardens or houses such as there are at Roehampton, Eltham, and Mottingham, which have large grounds attached to them and which have a very small population upon them indeed.

12,496. (*Mr. Norman Bazalgette.*) Are they areas which in your judgment are likely to be soon built over?—No

12,497. (*Chairman.*) What becomes of the drainage of those places, they are not drained at all, perhaps?—The sewage, if any, upon them, is disposed of upon the lands themselves; at Roehampton the land drains into the Wandle, at Mottingham into the Cray, and at Eltham partly into the River Lee, and partly into the Cray. I may say the sewage is disposed of upon the land.

12,498. (*Mr. Norman Bazalgette.*) I believe Beckenham contributes sewage only to the main drainage system?—Yes; but I have taken the sewage as representing the small area from which we should get both sewage and rain.

12,499. (*Chairman.*) Does the undrained part drain into the Thames both north and south?—Yes, mainly it drains into the Thames, that is to say, the 10 miles.

12,500. Does the part which is not drained into the intercepting sewers drain into the Thames in any way?—Yes, it is in the Thames basin certainly; its rainfall passes into the streams.

12,501. But the sewage does not drain into the Thames?—No, it probably never will come into our drainage system.

12,502. Is there any metropolitan sewage that drains into the Lea which gets into the Thames that way?—No, it is all intercepted.

(*The tables were handed in, see next page.*)

12,503. (*Mr. Norman Bazalgette.*) Now we will deal with Mr. Baldwin Latham's criticisms upon the main drainage first. I do not propose to read the evidence which he gave to the Commission, but if they will allow me I will state it shortly and refer them to the questions and answers. Mr. Baldwin Latham, at Nos. 7765, 7768, and 7779 quoted your evidence, I believe, on the great London Drainage Bill of 1853, and drew the inference from it that there would be an overflow from the present system into the river upon occasions varying from 80 to 100 days; what do you say with respect to that?—First, I say with respect to that, that any opinion which I might have expressed in 1853 about the scheme before I prepared any scheme myself, can hardly be taken as evidence of what is taking place at the present time; but the conditions to which I referred at that time were very different from the conditions of my own system of drainage, that is to say, whilst the great London drainage scheme proposed to deal with 43 square miles, they proposed to intercept the sewage of that 43 square miles by one sewer only of 10 feet in diameter.

12,504. Whom was the great London drainage scheme prepared by?—I can hardly tell you that. The promoter of it was a Mr. Morewood, who was not an engineer, but he had some engineers supporting it in Committee.

12,505. You were not responsible for that system?—No. The great sewer was to be capable of discharging 19,000 cubic feet a minute, whereas my three northern outfall sewers when united in one are capable of discharging 33,000 cubic feet a minute. I deal with a larger area, but if you reduce it to the same area you will see I have provided 50 per cent. more discharging power from the same land than this great London drainage scheme had done. I gave evidence in 1853 before the Committee that if that scheme were carried out, in my judgment there would be an overflow into the Thames on from 80 to 100

5th April 1883.

| Area of Metropolis [North] *not* drained into intercepting sewers. | 1·47B | | | | | |
| | 49·97 | | | | | |

A. Of this area 3·40 square miles is common or park land, and 0·87 square miles is water.

B. This area consists of parts of Hackney Marshes, North Woolwich, and a detached part of the Metropolis near Muswell Hill.

C. In addition to the above, the district of the Hornsey Local Board contributes sewage from a present population of about 22,000, the quantity being restricted ultimately to 500 cubic feet per minute. A part of the Stamford Brook drainage area contributes also the sewage from a small population, but its number cannot be ascertained. The same area also contributes surface water to the Metropolitan system, but the Metropolitan Board have determined to intercept this from their sewers and discharge it into the river at the extreme western boundary of the Metropolis. This is one of the works included in the 1,500,000*l.*, to be expended to prevent floodings from rain.

| Areas of Metropolis (South) *not* drained into intersecting sewers. | 16·57E | | | | | |
| | 67·78 | | | | | |

D. This contains 3 square miles of common land and park, and 0·56 square mile of water.

E. This contains ½ sq. mile of common land and parks, 3½ square miles of marsh lands, 2·15 square miles draining away from the Metropolis, and the rest is land of a rural or agricultural character, situate in the localities of Roehampton, Eltham, and Mottingham, which will never probably be more than sparsely built over.

F. In addition to this, 0·92 square mile of Beckenham contributes sewage only to the intercepting system.

days in the year. Mr. Baldwin Latham says, if that is so there must be an overflow from your sewers on from 80 to 100 days in the year. I say the argument is not correct, and I shall show by-and-bye that the deduction is not correct.

12,506. (*Chairman.*) You say the deduction is not correct, because you have given a larger discharging capacity?—I have given a larger discharging capacity, that it is larger in proportion to a given area than that scheme proposed upon the north side; then upon the south side it is very much larger. Upon the south side the area to be intercepted by the great London drainage scheme was not stated, but the discharging capacity of one sewer, 6 feet in diameter, was to be 5,300 cubic feet a minute, whilst the discharging capacity at my outfall sewer for the south side is 19,000 cubic feet a minute, or 3½ times the discharging capacity of the great London drainage scheme outfall.

12,507. (*Mr. Norman Bazalgette.*) Then I think we may deduce, as a matter of course from what you

have told us, that, assuming the great London drainage scheme were discharging with its limited capacity, assuming that there were an overflow from it on from 80 to 100 days in the year, it does not follow that there would be the same overflow from the intercepting system?—No.

12,508. I will deal next with Mr. Baldwin Latham's allegations in his answers to questions 7456, 7749, and 7751, where he states that no provision was made in the discharging capacity of the outfall sewers for the sewage of the western district; what do you say to that?—You will remember that when we designed the main intercepting system it was proposed to take the greater area upon the north side of the Thames to the outfall at Barking; but it was proposed to take the low-lying district at the western end and deodorise its sewage, that is, as regards the western district. A design was got out in the first instance with that view. Subsequently it was determined not to deal with the western district by deodorisation, but to connect it with the main system, and take the whole to Barking. Now, Mr. Baldwin Latham argues upon that, that the outfall sewers had been designed for a district without the western district, and that when the western district was added to it the outfall sewer was so small that it was not of the right proportion. I will show you that he is incorrect in that statement. This is my Report of 1856, in which very careful calculations have been made, showing at every point of the intercepting sewer what quantity would come in at those points, and making up the total quantity to be carried off. That quantity is made up in this way: we take the sewage at so many gallons a head. We take the maximum flow at double that quantity, and then we take a quarter of an inch of rain running off added to that, and taking the populations and the areas, we arrive at each point at the quantity to be intercepted. Now, that table shows that the quantity to be intercepted by the northern high level sewer after it had accumulated it all and got to the eastern end of London, amounted to 3,965 cubic feet a minute, the middle level sewer to 14,345 cubic feet a minute, and the low level sewer to 9,130 cubic feet a minute, together making 27,440 cubic feet a minute; and the western district gave 5,130 cubic feet a minute. Including the western district, therefore, the total quantity to be intercepted was 32,570 cubic feet a minute. Now, Mr. Latham has already told us, and it is a fact, that the outfall sewer will discharge 33,000 cubic feet a minute.

12,509. Those are the three outfall sewers, the high, the low, and the middle level?—Yes, the three sewers; each will discharge 11,000 cubic feet a minute; therefore the outfall sewer is a proper size for taking off the whole of the sewage of the western district. Mr. Latham said: Yes, you were constructing the outfall sewer before you determined to take the sewage of the western district into it. That was quite true; we were. But we knew that we must have made these sewers 8 feet 6 inches in diameter to take off the sewage of the high, low, and middle level sewers without taking the sewage of the western district; and we also knew there were differences of opinion as to whether the western district should be dealt with by itself or brought into the main system; therefore we said, we had much better make our sewer of 6 inches larger diameter in case the western sewage should be brought ultimately into the system; and we were making those sewers when it was determined not to deodorise the sewage of the western district, but to carry it into the outfall sewers.

12,510. (*Chairman.*) I should have thought the question was not so much what you had calculated or arranged, but what is the fact now; do the sewers carry off the requisite quantity?—Yes, they do.

12,511. I should have thought that could have been proved as a matter of fact; you have gauged the quantity discharged.

12,512. (*Mr. Norman Bazalgette.*) Is the western district at the present time drained into the outfall sewers?—I think, if you will let me put it in this way first, I shall come back at last to what you desire.

12,513. (*Chairman.*) I can quite understand that you are very desirous of showing that your calculations are right, but you must take care that you do not overload my memory and faculties with figures and facts?—I only desire to satisfy the Commission as to the precise position of things.

12,514. (*Mr. Norman Bazalgette.*) I think we might dispose of it in this way; is the western district at the present time drained into the metropolitan outfall sewer?—Yes.

12,515. And there is sufficient capacity in this sewer for so draining it?—Yes.

12,516. So that Mr. Baldwin Latham is wrong in saying that it was not provided for in the first instance?—Yes.

12,517. (*Chairman.*) You say, as a fact, that the sewers are large enough, and do carry off the sewage, except when there is a rainfall above a certain amount?—Yes, I do.

(*Chairman.*) Is that disputed?

(*Mr. Webster.*) I do not quite know in the way in which Sir Joseph Bazalgette puts it, whether it is or not; it is a question of degree how often they do and how often they do not.

(*Chairman.*) As I understand, if there were no rainfall they would always carry off the sewage.

(*Witness.*) Yes, they would.

(*Mr. Webster.*) I think in all probability that is the fact, but I must not be taken as exactly admitting it.

12,518. (*Chairman.*) The next question is, what quantity of rainfall would make them insufficient?—Yes, that is so; we shall come to that point directly.

(*Mr. Webster.*) I do not think Mr. Latham anywhere said that if there were no rainfall the sewers were not sufficient to take off the sewage alone.

(*Chairman.*) He rather suggested to us that Sir Joseph Bazalgette had lost sight of certain matters, and consequently had not made adequate provision. I can quite understand that Sir Joseph Bazalgette would controvert that, but after all it comes to this, are they sufficient, and he says they are.

(*Mr. Abernethy.*) Plus the $\frac{1}{4}$ of an inch of rainfall.

(*Witness.*) It is difficult to give it in two words without following out the reasoning.

12,519. (*Mr. Norman Bazalgette.*) The next allegation of Mr. Latham's is that no rainfall could have been discharged at Barking in 1875; that will be found in answer to questions 7739–40. As these are two short answers, I may as well read what Mr. Baldwin Latham really did say. At question 7739 he was asked, "What you mean is, that the amount that actually "flowed off at Barking in 1875 was below what is "found to be a correct estimate of the sewage "per head"; to which he replied: "That is so. "(*Q.*) And of rainfall at Barking that year"—that is, in 1875—"there was none that flowed off?—"(*A.*) Although there were 29 odd inches of rainfall "that year there was not any that flowed off at "Barking." What do you say to that?—Mr. Baldwin Latham arrived at that conclusion upon two assumptions; one was that the water-supply was the same upon the north side as upon the south side in cubic feet per head, whereas upon the north side, in answer to question 7726, he has correctly stated the water-supply upon the north side to be 30·4 gallons per head; so that he had overstated the water-supply, and he had also not drawn attention to the fact that the sewerage of the western district in those two years, 1875–6, had not been diverted to Barking. Now, making allowance for those——

12,520. (*Chairman.*) Let me see if I understand exactly the effect of your answer. When he says that "the amount that actually flowed off at Barking in "1875 was below what is found to be a correct "estimate of the sewage per head," does that mean therefore that some of the sewage must have found its way into the river by the overflow sewers?—Yes, that was the assumption.

12,520*a*. That is what it means?—Yes; Mr. Baldwin Latham's statement is, that taking the years 1875 and

*Sir J. W. Bazalgette, C.B.*

11 April 1883.

1876 you had not the full water-supply or scarcely anything over the water-supply coming down to Barking; therefore all your rainfall must have gone into the river by the overflows. Now that was a mistake upon the ground——

(*Chairman.*) Not only all your rainfall, but some of your sewage, because it was "below what was "found to be a correct estimate of the sewage."

(*Colonel Ewart.*) A mixed volume in proportion to the amount of the rainfall.

(*Witness.*) In the first place the water-supply was estimated at 31¼ gallons per head of the population instead of 30·4 gallons, as it should have been; and in the next place it was estimated upon the population of the western division; whereas the system was not complete in those two years, and their sewage was not then coming down. If you take what was actually taking place upon the north side in the year 1881, when we have the actual population and can get at it more correctly therefore, you will find that the daily discharge of sewage at Barking would be 77,739,032 gallons, which, deducted from the total quantity discharged at Barking, namely, 89,404,916 gallons, leaves a surplus of 11,665,884 gallons, or 1,866,525 cubic feet for a rainflow for 51 square miles, which is equal to 36,600 cubic feet per square mile, or $\frac{1}{6\cdot3}$ of an inch in depth for every day throughout the year. Now that represents in 365 days a total depth of 5·8, nearly 6 inches of rainfall, running off at Barking. Six inches of rainfall running off at Barking would represent nearly half the annual rainfall, as I shall show you presently that 6 inches running off represents very nearly 12 inches falling.

12,521. (*Chairman.*) Taking 12 inches as falling, that is half the rainfall?—Yes.

12,522. Even this seems to me to be a comparatively small matter, because they complained of the fouling of the water from sewage not being conveyed to Barking, but escaping at an earlier part of the river; there is just a little evidence that it is fouled, I think?—Mr. Baldwin Latham's evidence went to this: You are discharging sewage up in London at the overflows much more frequently than you have led us to suppose; and he set to work to prove that in a variety of ways. I am endeavouring to show that the different ways in which he set to work to prove that are not correct; that his data are not correct, and do not lead to that inference; and I also propose to give you some evidence of what actually has taken place besides. Still it seems to me necessary to meet each of the allegations, otherwise they stand as if they were correct.

12,523. But I mean the main battle has been upon the condition of things about the overflows?—I will take it very shortly.

12,524. (*Mr. Norman Bazalgette.*) Now we will go to question 7710 of Mr. Baldwin Latham's evidence, which I will read: "Taking a dry season would show "that what has been discharged would not come "from rain?—(*A.*) That would show that what had "been discharged then could not possibly come from "rain. The result of this showed that on the 12th July "1876 the quantity discharged in gallons at Crossness "on this particular day was 52,256,223 gallons, and "that was an excessively dry period; in fact, the "month of July was one of the smallest rainfalls that "ever was recorded, there had been no rain from the "24th of June to the 6th of July. On that day at "8 p.m., the sixteenth of an inch fell, and ·01 upon "the 7th, and ·02 upon the 8th, and then upon the "12th these experiments were commenced, and were "conducted throughout the day. Then from the "table of population in 1876 you will see that there "is a little over 1,000,000 of population and "52,000,000 gallons of sewage, so that you have "50 gallons per head, that is 30 of sewage proper "and 20 of leakage as I have already stated." What do you say as to Mr. Baldwin Latham's allegation that in July 1876 there were 20 gallons of leakage per head of the population discharged at Crossness?—Here Mr. Baldwin Latham has taken the water supply again on the south less than the actual supply, that is to say 51¼ gallons per head; but the water supply of the south side is larger than on the north, the average of the two is 5 cubic feet a head, but upon the north side it is smaller per head, and upon the south side it is larger per head, it is 32·5 gallons. Mr. Baldwin Latham's estimate was arrived at taking it upon that view that 30 gallons was sewage proper and 20 gallons derived from leakage, that he says in answer to question 7733; but he admits that the quantity discharged was at the rate of 46·88 gallons per head if estimated upon the entire southern population; and then he throws out 24 square miles and assumes 69,000 persons residing upon that 24 square miles which do not drain into the system; but I have shown upon the amended table which I have put in that the drainage area has been extended since that period, and that practically the whole of the population is draining into it and will do. I have also reduced the area not drained to 10 miles under the extended drainage system, upon which there is a very small population. The greater portion of this area consists of such places as Plumstead and Greenwich Marshes, open lands surrounding Eltham and Bromley, Tooting and Roehampton, Bosthall Heath, Woolwich, and Plumstead Commons, Blackheath, Tooting, Clapham, Wandsworth, Putney, Wimbledon, Streatham, Peckham, and other commons and suburban parks. Now the actual discharge upon that day was at the rate of 46·88 gallons per head, and if you deduct from that the actual quantity, the 32½ gallons instead of leaving 20 gallons to be accounted for it leaves 14·38.

12,525. Which upon Mr. Baldwin Latham's showing would be called "leakage"?—Which Mr. Baldwin Latham said he assumed to be leakage.

12,526. How do you account for the 14 gallons?—That 14·38 gallons per head amounts in point of fact to 16,000,000 gallons a day; that is to say upon a dry day after taking the water supply to the population there was an excess of 16,000,000 gallons a day to be accounted for. Now that is to be accounted for in two or three different ways. I will first refer to a report which I made upon the Bermondsey inlets. The Bermondsey tanneries have two inlets into the Thames which have been the subject of great trouble to us for some years, they have the right of letting in the water from the Thames into their tanneries, and they let it in in very large quantities, and we have to deal with it in the sewers. On the 9th of January 1877 I reported upon the subject.

12,527. (*Chairman.*) Let me see if I appreciate this matter. This is no imputation upon your calculations, but it is a suggestion that from leakage the sewers are not adequate?—That is the purport of it. I almost think I had better read the whole report, it is not a long one,

12,528. (*Mr. Webster.*) What is the date of that report?—The 9th of January 1877. The report is as follows, "Under the several Commissions of Sewers "that preceded the present Metropolitan Board of "Works, a culvert, two feet in diameter, which "supplied water from the Thames at St. Saviour's "Dock, Bermondsey, to certain tan yards right and "left of Russell Street, Market Street, &c., was under "the control of those Commissioners. Their sluice "keeper admitted the water and shut it off for the "benefit of those who were entitled to the supply, "subject to the safety of themselves and their neighbours being secured. In those days any excessive "admission of water charged the comparatively "small, shallow, and tide-locked sewers; but when "the main drainage system was constructed, water "might be admitted without check, as the surplus "ran off into the deep main sewers and was carried off "by the pumps at Greenwich and Crossness. Since "the year 1855, that is from the constitution of the "present Board, the control of the culvert has been "under the vestry of Bermondsey, and the quantity "of water has greatly increased. The water may be "seen flowing through the tan yards unchecked, and "the experience at the Deptford pumping station is

" that, even in the most dry weather, the quantity of " water which has to be pumped greatly increases as " the tides increase in height to spring tides. At " *ordinary* tides the calculated quantity of water " which can be taken by the culvert alone is 2¼ " million gallons in 24 hours, or nearly one-twelfth of " the daily average at Deptford pumping station. " At spring tides this is much increased. It seems to " me that the Metropolitan Board of Works might " fairly ask Parliament to put the control of this " important inlet into their hands. As steam power " for manufacturing purposes increases in the Metro- " polis the quantity of clear water used for condensing " also increases. One large mill in Belvedere Road, " near Waterloo Bridge, sends between a quarter and " half a million gallons into a district sewer from " whence it passes into the main sewers. If possible " some check should be put upon this." Then again upon the 13th of May, 1881, I reported upon the same question, " Since the completion of the low level system " of drainage, very large quantities of water are allowed " to flow unchecked through the culvert into that " system, thus increasing the cost of pumping at " Deptford and Crossness, and hence the necessity for " the Board having the control of the culvert. The " Board fully recognised this necessity, and by their " direction a clause was inserted in the Thames Flood " Bill for the purpose of securing to the Board such " control, but the clause, in consequence of some " opposition in the Select Committee, was ultimately " withdrawn. I have now reason to believe that if " a representation were made to the vestry of " Bermondsey they would be likely to accede to the " proposition that the culvert in question and an " 18-inch iron pipe at Bermondsey Wall, which " supplies some of the tanneries with water, should " be taken charge of by this Board, provided that all " existing rights were respected." Now these culverts and the water supply for the manufacturing purposes took off at least 4,000,000 gallons per diem let into the sewers. That accounts for one-fourth of it. Then the sewers upon the south side, which were constructed many years ago in a flat district, are exceedingly flat, having very little fall, and they are apt to accumulate deposit, and for the purpose of removing that deposit there are 40 inlets, one half of which are under the control of the Metropolitan Board of Works, and the other half under the control of six of the vestries.

12,529. (*Mr. Norman Bazalgette.*) Or district boards, as, I believe, some of them are?—Or district boards.

12,530. Will you state what they are?—Wandsworth, Lambeth, St. Saviour's, St. Olave, Bermondsey, and Rotherhithe. Now that flushing is carried on daily in dry weather by gangs of flushing men, who take certain lengths and flush them out on different days, they do not keep any record of the way in which they flush them, and I have been unable to get at the quantity either from them or the district boards. I have been taking some trouble to try and arrive at it, but I cannot do so. All I can say is, that without being able to give an estimate of the quantity, to the best of my judgment it may be fairly assumed that one-fourth comes from manufactories and tanneries, probably another fourth comes from the Board's flushing, another fourth from the flushing of the district boards, and the remaining fourth from leakage; that is what I believe.

12,531. So that you say the 20 gallons per head, which Mr. Latham ascribed to leakage, is really to be accounted for by water put into the sewers by the Bermondsey tanneries and by the inlets which are used for flushing the district sewers?—Yes.

12,532. (*Chairman.*) That shows, if correct, that Mr. Latham is wrong, but how does it affect the matter before us, I do not quite see; the sewers have to discharge this quantity of water, is not that so?—No, my lord, not quite so. In the first place, as regards the tanneries, I say that is a thing which ought to be checked and kept under control. As regards the flushing it does not take place in wet weather, which is the time when the capacity is required in the sewers.

12,533. He is speaking of a particular day?—A dry day upon which we got a gauging. Mr. Baldwin Latham made the remark that it was a very strange thing that we should have made gaugings of the flow at the time that they were flushing. Now that gauging was not made with any particular object except just to see, under ordinary circumstances, how the sewage came to our pumps, everything was left to go on as it did usually, and a record was taken to see what could be done.

12,534. (*Mr. Norman Bazalgette.*) Now I come to a very important allegation. At questions 7633–7, the allegation amounts to this, that the population provided for is already exceeded by half a million?—That was arrived at by taking the figures in the report of Messrs. Bidder, Hawksley, and Bazalgette, at page 41, where the population given upon the north side was 2,353,900, and upon the south side 1,094,600, making a total of 3,448,500. He deducts that sum from the population given by the Census 1881, namely on the north 2,548,999, on the south 1,283,488, making a total of 3,832,487, showing an excess in 1881 of 383,537, to which he adds 50,000 for the outlying districts, and for increase up to the present time 66,463, making a total increase of 500,000 people to this time, and I am disposed to adopt his figures. I do not think that they are far wrong, but in the capacity of the intercepting sewers provision has been made for double the average flow. Now double the flow is the same thing as the ordinary flow upon double the population, and that double flow was over estimated. We had not in designing the intercepting system made allowance for treating with so large an area. We treated it as if it had been a smaller area, and as if the maximum flow which takes place, say at about 10 o'clock in the day, produced the maximum flow in all parts of the system. But the fact is this; supposing the maximum flow to be at Bow, or Greenwich, at 10 o'clock, and to flow off to the outfall at the rate of a mile and a half an hour, that has flowed off long before the sewage from Bermondsey has come down to it. The sewage from Bermondsey has flowed away long before the sewage from the western district, and that has averaged or equalised the flow. Now from the gauging we took we found that the maximum flow instead of being double is only 40 per cent. more than the average flow.

12,535. (*Chairman.*) Do I understand you to say that this thing did not occur to you?—It did not. We said, when making our design, we will provide for such a population, we will provide for the maximum flow being double the ordinary flow, whereas we find that instead of being double it is only 40 per cent. more. Now the result of that is this, that assuming that the population at the present time to be as stated in Mr. Baldwin Latham's table, 3,975,468, and assuming the maximum flow to be 40 per cent. upon that, it would be equivalent to a population of 5,565,656, with a uniform flow; but the population actually provided for with a uniform flow is double what we provided for at the time of Messrs. Bidder, Hawksley, and Bazalgette's report, being 6,897,000, so that there is a balance of 1,331,344, supposing the flow to be equal, but making allowance for the additional 40 per cent. that gives really room for an additional population of 950,960, nearly 1,000,000; that is to say, with the 40 per cent. flow upon a total population of 4,926,400, or nearly 5,000,000.

12,536. (*Mr. Norman Bazalgette.*) That population, according to Mr. Latham's table, would be arrived at in the year 1896?—It would. I do not quite agree with Mr. Baldwin Latham's table as to the increase of population, for if you observe, London is getting filled up, and it will not increase. It is shown that it is not increasing as fast as it did formerly, but without picking holes in that, let us take it as it is stated, and that carries us to the year 1896, nearly the end of the present century.

*Sir J. W. Bazalgette. C.B.*

11 April 1883.

12,537. Now we will pass from Mr. Baldwin Latham, and I will put this to you; When you gave your evidence on the previous occasion, you stated in answer to question No. 9 that "It appeared from "tables of rainfall that there were only from 14 to "21 days in the year on which the rainfall exceeded "the rate of quarter of an inch in 24 hours; there- "fore we said, if we can divert the sewage from the "river in dry weather altogether on all those days "excepting the 14 to 21 according to the season (a "very wet season has been 30 days) we shall suffi- "ciently divert the sewage from the river to make it "clear." Mr. Symons disagrees with you. Will you tell me in what way you believe Mr. Symons' criticisms upon that answer were wrong?—In the first place Mr. Symons based his calculations upon years subsequent to 1856, when the rainfall has been, as he admits himself, excessive. Prior to that, the actual number of days which has been taken out upon which over a quarter of an inch of rain fell, was 25; but I was not speaking of rain falling, but of rain running off. My answer in the latter part of No. 9 shows that provision was made not for a quarter of an inch of rain falling, but for a quantity equal to a quarter of an inch running off. Now I wish to refer to the gaugings in Appendix No. 4 of the Report of Messrs. Bidder, Hawksley, and Bazalgette.

12,538. (*Mr. Abernethy.*) You provided for the quantity actually running out of the outlet?—Our provision is for the quantity running. I now draw attention to a table put in the Report of Messrs. Bidder, Hawksley, and Bazalgette, showing the gaugings of a sewer in Savoy Street. This shows that the quantity of rain flowing off in the case of the Savoy Street Sewer was 64½ per cent. of the total rainfall, this being a town area paved and built over. In a town area the quantity running off would be much greater than in fields where it would be absorbed.

12,539. (*Mr. Webster.*) That is running off in that time—in 36 hours is it not—not actually flowing off altogether?—Yes, "in the above-mentioned time," it is so. And in the case of the Ratcliff Highway Sewer, 48 per cent. of the total rainfall was run off; and the conclusion is "that the foregoing abstracts are of themselves conclusive evidence that the rainfall of 0·4 is not likely to yield of itself more than a quarter of an inch. So we say that to get a quarter of an inch running off through the sewers you look to the number of times in which 0·4 of an inch fell, and in that case you expect to get your quarter of an inch running in, and in excess of that to get an overflow. Now there were, on the average, only 12 days upon which more than that quantity fell. Mr. Symons' observations refer to the years 1877 to 1880 inclusive, in which years he admits in his answer to question 6956 there to have been a rainfall above the average He has divided the quarter of an inch of rain falling in 24 hours into the hundredth of an inch per hour and has assumed four-hundredths of an inch of rainfall each hour to represent the same thing as a quarter of an inch of rain running off the whole area in 24 hours. Now four-hundredths of an inch of rain falling for one or two hours in the day upon a dry surface, and in many cases upon a very small area, would really produce no discharge into the sewers at all. A quarter of an inch of rain running off in 24 hours is the same thing, and is equivalent to one-hundredth of an inch in an hour; so Mr. Symons said, I will take the number of days in which one-hundredth of an inch fell in an hour, as those are the days upon which your sewer would have been full. Now if you will look at that diagram (*handing a diagram to the Commission*); that upper line represents one-hundredth of an inch. Suppose that quantity to fall upon this road opposite to us, it would hardly make it damp; you would hardly perceive it; so that to assume that that would pour so much water into my sewer as to cause an overflow, is something than can hardly be realised; it is too absurd.

12,540. (*Chairman.*) I am not quite sure that I follow you, but there is no magic in hours. If an hundredth of an inch in an hour would do it, two-hundredths of an inch in half an hour would do it—according to that reasoning—not your reasoning, but according to the reasoning against you?—The reasoning there is that if a quarter of an inch running off in your sewers in 24 hours will fill those sewers, then one-hundredth of an inch, which is the same thing, for one hour falling upon a surface will fill your sewers too.

12,541. You deny that?—Yes.

12,542. I was venturing to help you by suggesting that if that argument is correct, then the two-hundredth of an inch falling in half an hour would fill your sewer?—Clearly.

12,543. And the four-hundredth of an inch in a quarter of an hour would fill your sewers?—Yes.

12,544. Whereas your argument is that it would not be sensible—that it would not be perceived at all—you might go still further and make it almost infinitesimal?—You might make it ludicrous almost.

12,545. You might say that a six-thousandth of an inch falling in one minute would fill your sewers, which of course it would not?—It would not affect them.

12,546. (*Mr. Norman Bazalgette.*) Now I believe you have taken 104 days in 1877, upon which Mr. Symons has said that 0·4 of an inch fell, and you have taken the number of hours during which the rain fell at that rate, and you have shown upon how many days that fall actually occurred?—I have.

12,547. Will you state to the Commission the way in which you have done that, and what the results are?—The figures Mr. Symons has put in show that in the year 1877 four one-hundredths of an inch or over fell in an hour upon 104 days, and the assumption as it stood was that upon those 104 days the sewers must have been full, and some overflow taken place. I have analysed that and I find that of those days, on 40 days that quantity fell for one hour only in the day; on 24 days it fell for two hours; on 16 days it fell for three hours; on 15 days it fell for four hours; on three days it fell for five hours; on five days it fell for six hours; and on one day for eight hours. If I add those hours all up together it reduces the 104 days to 10·37 days of 24 hours each in which the rain was actually falling.

12,548. I will just take it shortly, will you give the result for 1878?—The result for the year 1878 shows that out of the 82 days there were 32 days when the rain fell for one hour, 22 days when the rain fell for two hours, and that there were 14 days when the rain fell for three hours and so on, all of them show very much the same result. In the end they show that in 1878 there were actually eight days of 24 hours in which that quantity was falling, in 1879 there were 10·4 days, in 1880 there were 8·4 days, adopting the same principle. If you take the year 1879, there were 40 days upon which the rain lasted for one hour only, and 19 days on which it lasted for two hours, and then it continues decreasing for the longer periods.

12,549. Does it not follow from this, that but a few if any of the rainfalls which have been mentioned would have contributed to the sewers a quantity equivalent to a quarter of an inch running off in them from the whole metropolitan area at the same time?—Very few of them, the necessary periods would be reduced very considerably.

12,550. As the hours upon which the rain fell were not consecutive, would that have an effect in encouraging evaporation?—Yes; we find in many cases where it has fallen for two hours or three hours, that there have been dry periods between, it has fallen for an hour, or part of an hour, and then it has dried and evaporated, and then rain has fallen again. There is another point which I aught to allude to, and that is this, that these rainfalls are recorded at Kew. Now it does not at all follow that because that quantity of rain fell at Kew, it fell over the whole of the metropolis. On the contrary, the probability is that

it did not fall upon the whole of the metropolis, upon any single occasion. I have taken out a statement of the rainfall at Kew, and at Greenwich during the same days for several years, and I beg to hand it in, (*handing in a printed report*), it is very remarkable as showing that the two do not coincide I think in any instance. When you have had a heavy fall of rain at Kew, you have had little or none at Greenwich, and the table is really very instructive in that respect. It shows that there is the greatest inconsistency in the fall as one might expect. An ordinary rainfall does not cover 117 square miles, the rain cloud passes over from one end of the metropolis to the other, and it is discharging first at one hour in one part, and another hour in another part. There is another table at the end in which I have got out the number of days, and the number of hours per day in which 0·4 of an inch fell, worked out very carefully.

12,551. Does that also contain the number of days worked out in the same way in which one-tenth of an inch of rain fell in an hour?—It does.

12,552. You might just give us the sum of the results of that table as we have not yet had it, without giving us the details. I will put them to you. In 1877 the rainfall lasted at the rate of one-tenth of an inch per hour for two days upon the average equal to 48 hours in the year?—Yes, and in 1878 you have a rainfall for 2·8 days of 24 hours; in 1879 for $2\frac{1}{2}$ days for 24 hours, and in 1880 for $2\frac{1}{2}$ days.

12,553. I think you have said already that $\frac{1}{100}$th of an inch, or $\frac{4}{100}$ths of an inch falling in an hour in dry weather would scarcely do more than wet the surface?—It would, that is all.

12,444. Would it do about as much in the way of charging the streets with water as a water cart?—I should think not so much, a water cart throws it more heavily upon it, but it does not cover so large an area.

12,555. Having dealt with the theory of the thing, I believe you have some record of the number of times on which certain overflows which have been watched have actually occurred?—I have.

12,556. Will you give those to the Commission?—I undertook to give, as far as I could, the number of times of overflow; it is not an easy thing; in fact it is only possible in five cases, two upon the north side and three upon the south. We can only do it at our pumping stations, or where some one has been placed in charge and has been constantly there, and I put in a Table showing the results of those, and afterwards I will give some explanation with respect to them (*handing in the following Table*):—

STORM OVERFLOWS.

| Year. | Rainfall for the Year at Greenwich. | Deptford Creek. | Vauxhall P. S. Effra. | Battersea Creek P. S. Falcon. | River Lea, Old Ford. | Western Pumping Station, Pimlico. | | |
|---|---|---|---|---|---|---|---|---|
| | Inches. | Number of occasions of Overflow. | | | | | | |
| | | | | | | From Rain. | Special. | Together. |
| 1872 | 30·0 | 20 | — | — | — | — | — | — |
| 1873 | 23·4 | 16 | — | — | — | — | — | — |
| 1874 | 20·0 | 9 | — | — | — | — | — | — |
| 1875 | 27·3 | 20 | — | — | — | — | — | — |
| 1876 | 23·9 | 19 | — | — | — | Not known. | | 25 |
| 1877 | 26·8 | 30 | — | — | — | Not known. | | 53A |
| 1878 | 29·2 | 17 | — | — | — | Not known. | | 43B |
| 1879 | 31·3 | 21 | — | — | — | 36 | 12C | 48 |
| 1880 | 29·7 | 26 | 25 | 23 | — | 24 | 6 | 30 |
| 1881 | 25·2 | 37 | 19 | 18 | 22 | 12 | 6 | 18 |
| 1882 | 25·17 | 39 | 18 | 14 | 18 | 10 | 1 | 11 |
| Average per year | 26·40 | 23·09 | 20·66 | 18·33 | 20 | 20·5 | 6·25 | ·6 |

A. More than half the time for cleansing Isle of Dogs syphon.
B. Do. Do. and forming shafts.
C. Forming connections, &c.

The places are upon the south side, Deptford Creek, Vauxhall Pumping Station (the Effra), and Battersea (Falcon Brook). Upon the north side we have the river Lea, nearly opposite Deptford Creek, and the Western Pumping Station, at Pimlico.

12,557. The first column in the Table you have handed in, shows the rainfall for each of those years at Greenwich, does it not?—Yes, it does. You will observe that in 1881 and 1882 there is a very large increase in the times of overflow, and I will give you an explanation about that directly. At Vauxhall we only put up this pumping station in 1880, and therefore I cannot go back before that time. In 1880 there were 25 overflows; in 1881 there were 19, and in 1882 there were 18. At Battersea, in 1880, there were 23; in 1881 there were 18, and in 1882 there were 14. Then we come to the river Lea at Old Ford. I am sorry to say I have only two years of that; the man that we had there formerly did not write and kept no record; he died, and since then we have had another man who has kept a record. It shows that in 1881 there were 22 overflows, and in 1882 there were 18 overflows. Then at the Western Pumping Station, in 1876 there were 25, and in 1877 there were 53; more than half of those were pumping into the river during the cleansing of the Isle of Dogs branch and syphon. At that time we pumped into the river and did the same the following year; but we have since arranged, in order to cleanse a certain length of sewer, to put a board across the sewer and pump the sewage across that board into the other side of the sewer, so that it should flow, keeping the portion of the sewer you want to cleanse free of sewage so that you can get into it. Then, in 1878, we put in a number of shafts into the low level sewer to enable us to get in and cleanse it more easily than we could with fewer shafts, and that in the years 1877 and 1878 caused a large number of overflows. In 1879, which was a year of considerable rain, there being 31 inches of rain, out of the 48 days of overflows, on 12 of those days we were performing connections with the low level sewer, and diverting the sewage from the river, so that the actual days of pumping into the river were 36 for rain. In 1880 there were 24 days for rain and six days for making connexions or doing works in the sewers. In 1881 there were 12 days overflow for rain and six days for getting into the sewer, and in 1882 there were 10 days for rain, one for working in the sewer, making 11 in all.

12,558. (*Chairman.*) How is it that there would be four times as much overflow at Deptford Creek as there was at the Pimlico Pumping Station?—I am going to explain that.

12,559. (*Mr. Norman Bazlagette.*) Will you just state what the averages are for each of the overflows for the 10 years?—Taking all these things into consideration, the average overflows during the 10 years, including all these things has been, at Deptford, 23·09 times in the year; at Vauxhall, 20·66, or $20\frac{1}{3}$ times; at Battersea, 18·33; at the river Lea, 20; and at the Western Pumping Station, for rain, $20\frac{1}{4}$, and for other purposes $6\frac{1}{4}$.

12,560. Is the average of all of them taken together 19·66?—I have not averaged it.

12,561. (*Chairman.*) Of course, upon these occasions the whole of the overflow is not sewage, nor is it rain; could you at all tell what per-centage of sewage went over and overflowed; you could not tell, I suppose?—No, it would vary so much with different rains.

12,562. Some of these overflows, I suppose, may have had an almost inappreciable effect upon the water of the river?—Where there is a very heavy fall of rain and it is continuous, it would have a very slight effect; it would be very highly diluted.

12,563. I suppose you may say that if the rainfall is small the overflow is small, and if the rainfall is large the overflow is large but is much diluted?—Yes, precisely.

*Sir J. W. Bazalgette, C.B.*

11 April 1883.

12,564. (*Mr. Norman Bazalgette.*) I see at question No. 9, when you gave evidence first, you said that when you were considering the main drainage system, you estimated there were from 14 to 21 days in the year when the storm overflows would come into action?—Yes, and in a wet season I should think it might rise from 20 to 30.

12,565. Referring to the Tables I see that the overflows range from 18 times to 23?—Yes, if you take it for rain alone. Now I wish to explain how it is that in the years 1881 and 1882 you get that excessive discharge at Deptford Creek, which the Table shows. This (*producing the same*), is a model which we had prepared for a trial which arose, which I am going to explain to you. This represents the high level sewer, coming down to Deptford Creek; the sewage under ordinary circumstances falls through this grating at the bottom of the sewer and passes into three iron pipes, which carry it underneath the creek into the outfall sewer, and it is so arranged that when the sewage flows into this sewer up to the height of the lower gate, it is discharging the calculated maximum quantity of sewage for the district. When it rises above that quantity and this flap opens, it flows over and into the creek; but it was found that this flap, in times of heavy rain, did not let off a sufficient quantity, that is to say, did not let it out of the sewer fast enough. So what is done is that a sluice keeper is kept there, and he lets go this fastening and discharges the whole contents of the sewer into the creek for the time being. Now in doing that (it is a narrow creek and there is a wharf opposite it) on one occasion it burst out with such force that it blew away the wharf wall opposite to it; it undermined the wall and that gave rise to an action.

12,566. That happened in the month of August 1879, and the action was in 1880?—The upshot of it was that the flapkeeper received instructions, "When "you find that the barometer is falling, and there is "an appearance of rain, and that the sewage is rising "very fast in the sewer, do not wait till it rises to the "top of the outfall, but let it go before, so that it "shall not go out with such force." He has acted up to his instructions, and has let it go rather more often than we expected; he has taken care of himself, no doubt quite rightly, but the result has been that he has let it go more frequently than we expected. We are now constructing a new outlet behind this sewer into the Thames itself, instead of into the creek; as soon as that is finished, there would be no necessity to do this any more, and the overflow will return again. I have no doubt, to the quantity at which it had previously stood, from 9 to 30 days.

12,567. Now, to pass from the storm overflows to the reservoir, what was the object of fixing the lowest part of the reservoir at 2·75 feet above ordnance datum?—The object was not to discharge the whole of the sewage at one time, but to discharge it over a period of 2½ hours; that was the original intention.

12,568. Why over a period of 2½ hours?—Taking about half the tide, not to discharge it immediately at high water, but so as to have it not all in one mass; it was considered better to let it go down the river and partial return than to pour it out all in one mass at high water; that it would become purified by the admixture with the Thames water, and would not return in the form of sewage.

12,569. (*Chairman.*) In order to do that, you did what?—We placed the bottom of the reservoir at the level to which the tide falls upon the average in 2 hours 40 minutes. The overflow weir is about 5 feet 6 inches above high water, so that when we open the sluices at high water there is first a very large discharge from the reservoir—it empties itself rapidly. Then, having come down nearer to the tide, it discharges itself more slowly as the tide falls, and is completely emptied in 2 hours 40 minutes. That is shown by Mr. Baldwin Latham's diagram of the tides. We call it 2½ hours, he makes it 2 hours and 40 minutes.

12,570. In 2 hours and 40 minutes the contents of the reservoir are emptied?—In 2 hours and 40 minutes after high water the tide has fallen to the level of the bottom of the reservoir, and therefore the sewage has flowed into the river, the reservoir having emptied itself.

12,571. But it will flow into the river after that, will it not?—If we keep the gates open all that has come in will flow out; as a matter of fact, we have kept the gates open a longer time, and have discharged four hours after high water; but that is because, as I have described, our reservoirs were too small.

12,572. If your reservoirs were larger, and you could discharge upon the first half of the tide, you would have less return to you?—If our reservoir were large enough, and we could manage it, we should close it 2 hours and 40 minutes after high water, instead of going on, as now, for four hours.

12,573. The consequence of which would be that you would have less return to you?—Yes, that is so.

12,574. But you said it was, you thought, objectionable to discharge such a great quantity all at once; why do you think so?—I think it better not to pour so large a mass into the river at one moment, but to give it a couple of hours time to flow off.

12,575. If you could let it off in the first half hour, the vessels about there would be in truth in a flood of sewage, and nothing else; would not that be so?—No, I do not think it would reach the middle of a river; it would make a larger mass, of course.

12,576. (*Mr. Norman Bazalgette.*) I believe, as a matter of fact, about one half of the contents of the reservoir is discharged upon the first hour of the ebb?—About 5 feet 6 inches.

12,577. And the remainder in the next hour and a half?—Yes.

12,578. I may, just to clear up this point, while I am upon the subject of reservoirs, ask you is it the fact that the reservoirs of the main drainage system were designed with a view of carrying out any chemical process or deodorization in them?—No, they were not. I may also say that the reservoirs are in this respect unlike the rest of the main drainage system; there would have been no object in making them, in the first place, large enough for the future population, because they can be added to now, and they can be added to 10 years hence, and it would have been a waste of money to build them at the present time of the size which will be required 30 years hence.

12,579. You told me when you were first examined that the Board of Works have, as a matter of fact, actually let the contract for enlarging the reservoirs, and are only awaiting the result of this inquiry to proceed with the work?—Yes, the work would have been in hand a year ago, but the Board determined to await the result of this inquiry. I think I have mentioned that the Board are now carrying out works for the getting rid of storm water more rapidly, and preventing flooding, the estimated cost of which is a million and a half, of which half a million is now in hand—one-third is in hand and the other two-thirds have yet to be carried out, and that two-thirds includes two sums for enlarging the reservoirs, 60,000*l.* for the southern reservoir, and 150,000*l.* for enlarging the northern reservoir.

12,580. Captain Burstal told us he took certain float observations in 1866, will you tell the Commission shortly what part you took in those observations, if any?—Captain Burstal received instructions from the Government to make float observations, and to test the original observations, and I received instructions from the Metropolitan Commissioners of Sewers to make them in concert with him, and though we did not ourselves follow the floats up and down, we met and arranged matters in concert.

12,581. You supervised the movements of the floats and checked the results, though you did not follow the floats yourself?—That is so.

12,582. When and for what purpose was the system of catch-pits introduced in London?—The system of catch-pits was introduced for the purpose of preventing deposit from getting into the sewers, that is say, the

road detritus and the heavier matter, and it has been very successful in doing so.

12,583. Can you give the Commission any idea of the quantity of road detritus which has been intercepted by these catch-pits in any given year?—I can. There are 775,000 cubic yards per annum removed from the streets.

12,548. A cubic yard is about equal to a ton?—Yes. Of that quantity 616,500 are removed by scavenging by carts, 133,000 tons are removed from the catch pits, the catch pits are placed by the side of the road to catch the heavy detritus and let the water flow over it, to prevent it going into the sewers, and 25,600 cubic yards are removed from the sewers. (I am taking the figures for the year 1878), so that the great bulk is removed from the surface, and then a large quantity from the catch pits, and a smaller quantity from the sewers themselves. There is a direct interest to us in doing that, inasmuch as it is very much more costly to get it out of the sewer than it is to get it out of the catch pits, and more costly to get it out of the catch pits, than to get it off the roads. I may say that of those quantities as nearly as we can estimate about 40 per cent. is road detritus, 40 per cent. is water, and 20 per cent. is garbage from the markets, and refuse.

12,585. Br. Frankland told us that he did not think the operation of these catch pits was efficient; what do you say to that. I presume the quantities you have given us are your answer to that?—They are efficient if they are properly looked after, if they are neglected and allowed to get full, they cease to operate, but if they are emptied from time to time they answer very well.

12,586. (*Chairman.*) But sewage would not get by that means into the river, it would only be the washings of the streets?—no, the sewage would not, it would only be the deposit of the roads and the manure droppings in the streets.

12,587. (*Mr. Norman Bazalgette.*) Would a sample of sewage taken at the outfalls, before the system of catch pits was introduced, afford in your judgment a fair criterion of the amount of suspended matter delivered at the outfalls after the system of catch pits was introduced?—Certainly not.

Cross-examined by Mr. Webster.

12,588. My learned friend Mr. Bazalgette has suggested to you that a comparison between the two samples would be fallacious. When do you say the catch pits were introduced?—I do not remember at the moment, but it was stated in my evidence before the last Commission.

12,589. (*Chairman.*) You cannot tell us anything about the mud banks and smells, or anything of that kinds?—No, I cannot.

(*Mr. Norman Bazalgette.*) The Corporation have called five or six engineers, all of whom have made different parts of the Corporation case, and Sir Joseph Bazalgette has confined his evidence to the drainage system.

12,590. (*Mr. Webster.*) A little speech has been made by my learned friend Mr. Bazalgette as to whether a particular comparison would or would not be reliable. I wish to know when this catch pit system was introduced, I am informed it was in 1846?—I will endeavour to get it as correctly as I can, but it would be dangerous to give you any particular date, it began to be used at one time and then its use increased in subsequent years.

12,591. Could you give us the number of catch pits at any intervals of years, say in 1870, and in 1880, and so on, because the mere general observation as to a sample before catch pits, and a sample after catch pits might be a truism; but I want to see what the figures are?—I beg to read my answer upon a former occasion in the Mud Inquiry. "It would be difficult "to say when they were first made some 30 years ago "there were very few of them, and they were of very "defective construction, that is to say, they were "mere pits which would receive the road detritus, and "when it rose to the level of the overflow, a good deal "of the detritus would go into the overflow sewer "and pass away." Then I say "about 30 years ago "considerable attention was paid to the subject of "forming catch pits," and that "since then they "have been very much improved and very largely "extended."

12,592. What date is that?—1880.

12,293. That takes us back to the year 1850, it refers to a time when the catch pits were largely extended and an improved kind of catch pit was introduced?—It is about 30 years ago.

12,594. Upon this question would you give us, if it is of any value at all for the purpose of comparison, the difference in the number of catch-pits at any epochs which you could pick out for yourself?—I do not think I could.

12,595. There is information upon the point is there not?—I cannot give you any information as to the number, because they were in the hands of so many vestries and district boards.

12,596. You have said that this enables you in some way to form a judgment upon the amount of detritus which goes into the river and that which does not. All you have given is the total quantity of detritus, which you have taken as 775,000 cubic yards, which you divide into three quantities, 616,500 removed by scavengering and carts, 133,000 from the catch-pits, and the balance 25,600 taken out of the sewers?—Yes.

12,597. That does not take any notice at all of what may have gone out along with the sewage?—It does not.

12,598. Therefore except that it tells us that so many tons are taken in those three ways, it does not give us any information at all?—It simply shows that this detritus did go into the river until it was intercepted.

12,599. Does the 25,600 go through the catch-pits?—Yes, it does.

12,600. That is something which the catch-pits will not intercept?—Yes.

12,601. Have you made any estimate at all of what the total road detritus due to the whole surface area of the streets is.

(*Chairman.*) You mean for the metropolis.

12,602. (*Mr. Webster.*) Can you tell us at all what does go out into the river and is not taken out of the sewers, because you have given us what was taken away in carts, and what was taken away from the catch-pits, and what was taken out of the sewers. I want to know if you have any estimate of what goes through the sewers?—Yes, we have made an estimate. What I understand you to want is the total quantity put on to the roads.

12,603. You shall give it me in any way you like. I only want the facts; you have only given to me those three figures, but those three figures you have given do not exhaust the question, because they simply give what is taken by carts, what out of the catch-pits, and what out of the sewers, are you able to give us what the balance of the road detritus is which passes through the storm outlets or the sewers?—I cannot give it you here, but it is a small quantity, I can tell you that.

(*Chairman.*) (*To Mr. Webster.*) Do not suppose I am finding fault with you, but I do not understand. Suppose Sir Joseph were to tell you that there was as much more unaccounted for or half as much more, what then?

(*Mr. Webster.*) In the first place it does contain, I will not say so much matter, but more or less offensive matter, there is no doubt it does contain, as Sir Joseph told us, the dung of the streets and other things which tend to produce noxious matter, but the important question is what is the specific gravity of the sewage which naturally comes out, and I wanted to know

*Sir J. W. Bazalgette, C.B.*

11 April 1883.

whether Sir Joseph meant to say that no detritus at all went out into the river, and if any did, what did, the three figures do not exhaust the whole question.

(*Chairman.*) The rest goes through the sewers, and is an element or portion of the offensive matter.

(*Mr. Webster.*) It is an element which must be considered.

(*Chairman.*) Is that so.

(*Mr. Webster.*) To a greater or less extent. I want the figures to be complete.

(*Witness.*) In the year 1878 there were 1,338 miles of macadamised roads, 274 miles of paved roads, 61 miles of paved courts, 22 miles of asphalte, and 15 of wood paving, making in all 1,710 miles of roads, and upon those roads were put in the year 1878, 307,700 tons of macadam flint or hoggin, and in addition to that I estimated that off the granite paved roads another 39 tons were probably worn away in the course of the year.

12,604. (*Mr. Webster.*) Is that all?—Yes.

12,605. You have spoken of 775,000 cubic yards, and you told my learned friend, Mr. Bazalgette, that a yard was equivalent to a ton?—Yes.

12,606. What you have given there as being put on is not half that?—No.

12,607. What would the rest be made up of?—The rest would be made up of 40 per cent. of water, 20 per cent. of garbage, and the refuse of markets, houses, and streets.

12,608. What you have given me is not what I asked for, which was not an estimate of the amount of granite or hoggin put on and worn away, but what the total amount of road detritus, water, and garbage was for the corresponding year for which these figures have been given. You said, I think, that you had an estimate somewhere or other of what the total quantity would be, showing the balance beyond the 775,000 cubic yards which does go into the river or disappears somewhere else?—No, I think I have given you all the figures I have.

12,609. Are you unable to tell us what you estimate to be the quantity of detritus that passes into the sewers?—I am unable to do so.

12,610. Do I understand that you have not considered this question of the effect of the present mode of dealing with the Metropolitan sewage; as you have not given evidence about it, do I understand that you have not considered it?—I have considered it.

12,611. Speaking generally, you do not deny, I presume, that there is a washing backwards and forwards of the sewage for a certain period, between, we will say, 10 miles, or I should think I might put it at 15 miles, or I will say 5 miles above and 10 miles below the middle point of Barking and Crossness?—I cannot speak to figures.

12,612. I said "speaking generally"?—I cannot speak to figures, because I did not conduct the experiments.

12,613. Forgive me for bothering you about the matter, but you have been with the Board for many years, and have considered this matter more than most people, I suppose; it is not an incorrect statement to make, is it, subject to what more accurate examination may show, that there is a washing backwards and forwards of the sewage from a distance of 10 miles below what I may call the middle point to five miles above?—Theoretically, supposing the sewage to remain unchanged, that is so.

12,614. I will come to that directly; have you in past years investigated the distance to which that oscillation takes place?—Yes.

12,615. When did you first investigate it?—When the float experiments were made.

12,616. When was that?—I think it was in 1856.

12,617. Will you tell us now if you recollect what conclusions you came to as to the length of distance, in the first place, that this carrying backwards and forwards was spread over?—Yes, about 12 miles from high water to low water.

12,618. Have you altered your opinion since with regard to that question of distance?—No.

12,619. Do you think it is about right?—I think that a float put in about high water would go down for about 12 miles and return again.

12,620. I was not dealing with the float. I was asking you the area over which you think the sewage would oscillate?—I did not enter into that question at all.

12,621. I have not much curiosity about a bit of wood floating up and down the river. I am here upon another subject altogether. I want to know whether at any time during the last 30 years you have formed an opinion as to the distance over which the sewage would oscillate?—No, I cannot say that I have.

12,622. At no time?—No.

12,623. (*Chairman.*) I thought you said 12 miles would be the distance it would travel upon a tide?—But Mr. Webster objects to my taking a float as representing the sewage.

12,624. I understand the effect of Mr. Webster's question is, supposing the sewage did not get mixed but continued to float up and down the river?—I considered that if it did not get mixed it would float down about that number of miles; that with a spring tide it would rise higher up the river, and that with a neap tide it would go further down.

12,625. (*Mr. Webster.*) As a mere question of floating, you consider it would probably be driven backwards and forwards over a distance of 12 miles?—Yes, I do.

12,626. Quite apart from chemical action, did you ever form an opinion as to during what period the oscillation would take place over that range before the sewage was carried out?—No, I never went into the question of what the sewage would do.

12,627. I want to put this to you. I am not dealing with the question of the capacity of your outfall, or the size of the sewers, or anything of the kind at the present moment. Had you formed no theory before the construction of these works as to the time within which the sewage would disappear and go to sea?—No, I have not. I believed that it would never go to sea in the form of sewage.

12,628. I am not going to suggest that when I use the word "sewage" it is to avoid the necessity of putting in every question the words "sewage which has been subject to chemical action." However, you did not form an opinion as to what period it would get to sea and never come back again?—I cannot say that exactly, because I was obliged to take into consideration the evidence afforded by the floats.

12,629. Do you agree with the evidence suggested by the Corporation as to the length of time in which the sewage, altered or unaltered, floats backwards and forwards before it reaches the sea?—I should not like to express an opinion upon that subject.

12,630. Did you form an opinion upon that subject at any period before the year 1870?—Yes, I did.

12,631. What did you assume then was the period during which, or over which, this oscillating action might take place, as distinguished from the space in which it would take place?—Again I am unable to answer that question, unless you permit my reference to the solid body unchanged.

12,632. Now have you formed any opinion yourself, from your experience, as to the effect of any chemical action, either dilution or oxidation?—I had formed an opinion that the dilution and the oxidation would destroy the sewage rapidly after its discharge into the Thames.

12,633. I would ask you first when you formed that opinion?—I formed that opinion before I designed the main drainage.

12,634. Was that the result of experiments made by yourself?—It was the result of general observation.

12,635. Pardon me, was it the result of experiments made?—No, not of any special experiments.

12,636. Is it embodied in any report?—It is embodied in several reports.

12,637. I should like you to tell me, if you c of any report in which you have dealt with the question of dilution and oxidation prior to this Commission?—I will ask leave to produce them by-and-bye.

(*Chairman.*) (*To Mr. Webster.*) Is the object of this to show that Sir Joseph Bazalgette designed this great work without contemplating what mischief he would do.

(*Mr. Webster.*) I merely meant this. I wished to suggest that it was not known what would be the effect of this large mass of sewage. I am exceedingly anxious not to appear here in any way on behalf of the City, as attacking the Metropolitan Board of Works in the slightest way. I am only here for the purpose of getting at the facts.

12,638. (*Chairman to the witness.*) How is that? Had you before you designed this work speculated upon what would be the effect of it, and whether the mixture and oxidation would have between them some effect, and what effect?—I had taken a good deal of trouble to inquire into the matter during the time I was designing the system. I had before me the effect of the sewage poured in at low water at London, and the effect at high water when diluted by a large body of water. I also went with Messrs. Bidder and Hawksley round to Manchester, Birmingham, and other towns to see the effect of putting sewage into their rivers, and to trace the sewage down a certain distance to see at what points it became destroyed and lost, and how soon the rivers purified themselves. So I took a great deal of trouble and care to look into the question before we fixed upon these points of outfall, and I think I shall be able to produce some reports in which I brought that out.

12,639. (*Mr. Webster.*) Of course I have only what is before me at the present time; what I want to know is this,—if you wish to postpone the answer until you can get the reports, by all means do so,—I want to know if the effect of oxidation was taken into account by you as a distinct integer which would counteract the otherwise injurious action after the sewage got into the river?—It was.

12,640. What was the value put upon that action or agent for the purpose of avoiding possible nuisance; to what extent was it supposed it would act?—I do not suppose I can give it you in figures.

12,641. Neither with regard to time nor volume nor anything else?—I have no doubt that at the time those elements were entered into very fully, but I have no record of it before me now. My attention is called now to a report by Dr. Letheby to us at that time, who had considered the matter very fully.

12,642. If you can refer to any reports either now or afterwards, will you do so?—Yes, I will do so afterwards.

12,643. It amounts to this, that generally the possibility of oxidation assisting to deodorise the sewage would have been taken into consideration?—It was.

12,644. But to what extent it would operate you do not recollect; whether it was put down as a question of time or volume?—It was both.

12,645. I know, in general terms; but taking the volume you had to deal with, to what extent?—Speaking from this distance of time, I cannot give you the figures.

12,646. Of course a small drain turned into a comparatively small stream may get oxidised, and not do much harm in consequence. On the other hand, if you had a much larger volume of sewage going into the same water, it would take a much longer time to oxidise?—We went into it in that way.

12,647. And having gone into it in that way, I should be glad to see any report which would embody the effect of your inspection. Did you at all deal with the question of the solid matter? I have no doubt you did?—We did.

12,648. Did you form an opinion as to what were the solid constituent parts of the sewage going into the Thames?—Yes.

12,649. Do you remember what that was?—I do not.

12,650. Has that changed, or are you assuming that the figures you have calculated are correct?—I cannot recollect what those figures were.

12,651. And you cannot tell me whether your present judgment has caused you to deviate from those figures at all?—I do not recollect.

12,652. It was imagined, was it not, that although theoretically there would be this floating backwards and forwards, yet to a great extent the sewage would be carried direct out to sea?—I do not think so; not as sewage.

12,653. You say "as sewage," I say carried out to sea so as not to remain in the water in any way noxious. Perhaps I ought to put this to you; besides the oxidation which is largely mixed up with the dilution, was there any other chemical action that you relied upon, or that you thought was an assistant?—No, I think not.

12,654. It was thought to a great extent that you had gone so far down, that there would be, comparatively speaking, a short period in which noxious sewage would remain in the river?—Yes.

12,655. Were you one of those who thought you need not have gone as low as Barking?—No, I always recommended Barking.

12,656. There wers others, were there not, who thought that Barking was too low at that time. I have a recollection of reading that in some of the reports?—I have heard it so stated, but I do not remember it.

12,657. The importance of the lower reaches of the Thames, from a port point of view, is increasing every year. I am referring to the fact of vessels passing through it, and the increased trade coming to the Thames; therefore, from a sanitary point of view, you would admit that the lower reaches are much more important now than they were 20 years ago?—Yes.

12,658. The main and pressing question you had to deal with at that time was that the Thames was a nuisance under the noses of the people living in London?—It was.

12,659. And you would not deny, I presume, that if the same thing, though not to the same extent, was growing up again in these lower reaches, that would be a serious evil?

(*Chairman.*) Is Sir Joseph an expert upon this question? He is a gentleman whose opinion I should be glad to have on anything, even upon an astronomical question; I have no doubt he would be able to instruct us, but do you think it is necessary to put this question to him?

(*Mr. Webster.*) The idea was, before the date of the discussion as to the outfall, that the sewage should not be returned to the metropolitan area. It may be (but I do not think the Commission would come to that conclusion), that they have fulfilled, or still do fulfil, the letter of the restriction existing or proposed, or wished to be arrived at at that time, namely, that the sewage should not be permitted to flow back into the metropolitan area, but there may be the same nuisance growing up to the lower reaches of the river, and what I wanted to get at was whether Sir Joseph Bazalgette considered that if that was the state of things——

(*Chairman.*) It would take less time to ask him the question than to discuss it, because he is a gentleman whose opinion we should be glad to have upon anything.

12,660. (*Mr. Webster.*) Assuming that there is growing up, as I have said lower down in the river, that which will become a nuisance especially in hot weather from the smell, and the condition of the water. do you consider that that is a thing which must be borne with and not corrected by taking the outfalls elsewhere?—If you begin by assuming that there is a nuisance.

12,661. Growing, I do not say actually existing at the present time, but growing up?—If there is a

*Sir J. W. Bazalgette, C.B.*

11 April 1883.

nuisance it should be removed, but I do not admit that there is a nuisance.

12,662. Is it your opinion that the nuisance in the Thames in the old times was solely due to the water, that it arose entirely from the sewage in the water? —Yes, I think so, in the water and upon the banks.

12,663. I was coming to that, do not you think it arose to a very considerable extent from the sewage deposited at the bottom of the river and upon the banks giving off gases?—I think it did.

12,664. It is your opinion, is it not that this nuisance from the soil upon the bottom of the river and upon the banks was not the result of a merely temporary deposit but was aggravated by the length of time that the deposit had remained there?—I daresay it was.

12,665. I mean that a sewage bank, or a bank that would be affected by sewage mud is not of necessity the result of the growth of a couple of months; it may take much longer to grow up?—It would take some time to go if it is of any extent.

12,666. Have you yourself ever examined the question in hot weather of the existence of smells in the water?—No; I am, fortunately or unfortunately, a bad person to judge of that; my sense of smell is not very quick, and I should not detect it rapidly.

12,667. I am not now dealing with an expert's analysis of the water of the present time or last year, but I want to ask you if any person is coming who will give us actual evidence as to the condition of the water in the last five, or six, or seven years?—Yes, there is.

12,668. Now will you give us, in the shape of a table, or somehow or other, how often or over what period sewage has been discharged from the high level and the tower level, that is to say, from the northern and the southern outfalls respectively, after high water? —We have discharged up to four hours after high water, and sometimes we have been obliged to discharge before the beginning of ebb tide, that is to say in a flood when you have heavy rains.

12,669. I am afraid I want it a little more in detail, if you will give it me. I presume a record is kept of the discharge?—Yes.

12,670. There can be no difficulty in putting in a tabulated statement for, say, the last eight years, the hours of the outpouring or letting out of the sewage upon the north side and the south side respectively?— I do not think there would be any difficulty about that.

12,671. Would you also kindly show upon that table the instances in which it began before high water, and of course the duration of it; in all other cases I presume it began at high water?—Yes.

12,672. What did you contemplate as being the time which would be required for emptying the reservoirs?—Our reservoir is arranged for emptying itself in 2 hours and 40 minutes after high water.

12,673. You can open when you like, because I understand if it is anything like full, there is always sufficient head to enable the sewage to run out even upon the top of the highest tide, is that not so?—Not all of it.

12,674. I did not say "all of it." I spoke of commencing to discharge. I assume you do not turn out the sewage before high water unless you have a pressure of sewage in the reservoir?—That is so.

12,675. In an ordinary high tide, how much below high water mark is your sill, you say it is designed to run for 2½ hours?—It is 8 feet below mean high water.

12,676. (*Sir John Coode.*) Is that the mean of spring and neap?—Yes.

12,677. (*Mr. Webster.*) And the tide falls, roughly, that 8 feet in 2 hours and 40 minutes?—Yes.

12,678. When the reservoir is full, what depth of water is there above the 8 feet sill?—13 feet; 13 feet 5 inches is the depth of the reservoir.

12,679. It amounts to this, therefore, that you have a head of somewhere about 5 feet which will run off even when the water is at the ordinary high water mark?—Yes.

12,680. You can of course continue the discharge as long as you like until the tide comes back again? —Yes.

12,681. And it will be the necessities of the supply of the sewage and rain water mixed together which would regulate how long the outfall was opened upon the one day or the other?—Yes.

12,632. You had better give us the same information for the southern outfall, if there is any difference? —There is very little difference, the southern outfall is rather deeper, and therefore there is a greater head upon the south side, it is 2 feet higher, the bottom is the same level, and it is 2 feet 6 inches deeper.

12,683. Is the bottom of the sill 8 feet below ordinary high water mark?—Yes.

12,684. But it is 15 feet 6 inches deep instead of 13 feet, is it not?—Yes.

12,685. Now, I will ask you a question or two about some of the things you have said to-day, with regard to the question of capacity. I am afraid I do not quite understand about the double flow, you made the sewers for double the maximum flow, I understand?—For double the average flow.

12,686. You made them for double the average flow of an assumed population for the day, that is so? —Yes.

12,687. And that without rain?—Yes, first; that is the first part of it, then we made provision for the rain in size.

12,688. The first estimate you dealt with was the sewage?—Yes.

12,689. You said to-day that the first thing you did was to assume double the population. Having got the estimated flow of the existing population, then you doubled it; is that correct?—No. What I stated was this, we took an assumed future population with an average flow of 31 gallons per head, then we said we will provide for double that quantity.

12,690. That is 62 gallons. It would either be double the population or double the flow from the same population?—Yes.

12,691. Now what did you add on besides that?— We added on a quarter of an inch of rain. I am reminded that with regard to some of the outlying districts we added only an eighth of an inch of rain.

(*Sir John Coode.*) Can you tell us what proportion one district would bear to the other, that is to say, the area for which you allowed a quarter of an inch compared to that for which you allowed an eighth of an inch of rain?

12,692. (*Mr. Webster.*) I think I can get it in answer to this question. First, I understand you to say that you adopt now the figures which Mr. Baldwin Latham gave of the population, namely, 3,832,441?—Yes.

12,693. Could you put your hand upon the figure of the population which you did actually take?—It was 3,448,500.

12,694. Will you kindly divide that into north and south?—North, 2,353,900——

12,695. But you are here reading off Mr. Baldwin Latham's figures?—No, I am now reading the quantity provided for by Messrs. Bidder, Hawksley, and Bazalgette.

12,696. You are quoting from the same report as was quoted by Mr. Baldwin Latham?—Yes.

12,697. Those are the figures upon which you acted?—Yes.

12,698. Having got that, taking your 31 gallons (which I presume you take the same on both sides as the ordinary flow)?—We did.

12,699. What did that come to? Have you got the figures there?—No, I have not got the figures here.

12,700. Now I want you to answer what Sir John Coode put to you, because it was a matter I was just going to put to you myself. Will you tell us, as nearly as you can, either in distances or sewers, where you allowed for the quantity of a quarter of an inch

of rainfall and where you allowed for one-eighth?—I will put it all in full for you.

12,701. Did you always allow as much as an eighth?—Yes.

12,702. I do not understand why you say the increase now is only 40 per cent. Would you just explain that to me again. I dare say the members of the Commission followed it. You say now experience shows that instead of estimating for a double flow you need only have estimated for an increase of 40 per cent. Do you mean that an increase of double the population would be only equal to 40 per cent.?

(*Chairman.*) The way I understood it was this, that he thought the sewage, instead of flowing at an average equal rate, would at one period of the 24 hours be double the average, and, therefore, he arranged for double what would be required if it were all flowing at the same rate in 24 hours; but he says, experience tells us that the maximum flow is only 40 per cent. above the average, and, therefore, he says, we have fortunately got a much larger discharging power than we should have had if we had known the truth.

(*Mr. Webster.*) That assumed the population remaining constant.

(*Chairman.*) Then he says, the population not remaining constant, I add the increase of population to my 40 per cent., and get to the conclusion that still I have more than enough.

12,703. (*Mr. Webster.*) Do I understand you to say that experience shows that the maximum flow is never more than 40 per cent. above the average?—The only actual experiment I have is that which was made at Crossness.

12,704. When was that experiment made?—The experiment to which Mr. Baldwin Latham has referred many times was made on the 12th July 1876; it shows at different hours of the day the quantity flowing off, commencing at 1 in the morning and continuing till 12 at night.

12,705. Do I understand you to say that your evidence about finding that 40 per cent. is the increase or excess above the average flow, is based upon that experiment only?—That is so.

12,706. You have no experiment with regard to the northern outfall at all?—We have not; we had not the means of doing that.

12,707. Do I understand you to say that from any data you can give us on the northern side, it never flows more than 40 per cent. as the maximum above the average which the population would show?—I cannot say that; we can only judge by what we have got.

12,708. Now I would like to ask you this. The south would be no criterion for the north for that purpose, would it?—Yes, I think it would.

12,709. You have got, according to you, 16 gallons per head per day, and we say more, which is due to exceptional circumstances; it is 16 out of 50 or 16,000,000 gallons, which is due to exceptional circumstances?—Yes.

12,710. The experience of other places is, is it not, that there are hours of the day when the flow varies much more than 40 per cent. above the average?—Yes, and that is our experience too. I explained in my evidence in chief why it was that when you are dealing with a large area, it necessarily reduces the rate of flow to a more uniform rate.

12,711. That is just what I was coming to. I want to get at this,—what data have you upon the north side of the Thames for saying that the maximum flow in any given 24 hours is never more than 40 per cent. above the average?—I can only say, from the experiments I have made upon the south side, which I believe to be under the same conditions as the north, that that is what I find to be the case, subject possibly to some variation, owing to water being let in from the Thames, which might have made it somewhat worse or somewhat better.

12,712. In the first place, I have already pointed out that that is one experiment only, and that is based upon what was flowing when there were 50 gallons a head flowing through as against 31 gallons of ordinary sewage. I do not see how the fluctuations in the 24 hours, when that exceptional flow of water was going through upon the south side, would be any criterion from which you would say as an engineer that the flow of sewage upon the northern side would never rise in any part of the 24 hours more than 40 per cent. beyond the average?—I think the tendency would be upon the south side to increase the maximum flow.

12,713. The tan yards counted for 25 per cent., you think, of this extra water?—Yes.

12,714. How do you get any information at all as to the mode of dividing it out into one quarter to the parishes, one quarter for yourselves, one quarter leakage, and so on?—I cannot get it any nearer than that.

12,715. Now, taking the question of rainfall, are we to judge of this by the eye. Do you ask us to look at this thin strip (*pointing to a diagram*) and ask us to consider that quantity falling and flushing the sewers at all?—Yes.

12,716. In what period is that supposed to fall?—In an hour.

12,717. Would the next strip flush the sewers?—If falling for an hour, it would probably contribute something to it.

12,718. You have had such things as flooding the sewers, have you not?—Undoubtedly, we have had as much as 2 inches of rainfall in an hour.

12,719. That is not quite the point; what I want to know is what from actual experience you find has been the effect, do you not find that a much smaller quantity of rain falling than this thick line, that is, the tenth of an inch, will cause flooding?—No, certainly not.

12,720. Do you remember the correspondence between the vestry of Paddington and the Metropolitan Board of Works in August 1878?—No, I do not.

12,721. Do you remember that the sewers were rising, so that building operations had to be stopped?—Yes, at Paddington.

12,722. Do you remember the quantity of rain that fell?—Yes, it was something very heavy.

12,723. Have you a record of it?—Yes, I have, but not here.

12,724. Would you mind bringing us that here upon the next occasion?—You are referring, I presume, to Mr. Whitehead's premises?

12,725. I am referring to the correspondence between the vestry of Paddington and your Board in August 1878, you reported upon that?—I do not remember what the report is, but I will look it up and see what it is.

12,726. While I am upon that, I want to ask you this: what opportunity, or have you any means of telling what was happening at the other storm outlets at any period of time?—No, I have given you all of which I have any record.

12,727. How many storm outlets are there?—I have stated it in my evidence-in-chief.

12,728. All those red dots upon the map are storm outlets?—They are. I beg to hand in a list of them.

*The following list was handed in:—*

STORM OVERFLOWS.

*North Side.*

| Level. | Size. | Outlet. | Position. |
|---|---|---|---|
| +3·0 | 6 ft. Bl. | Stamford Brook | At Hammersmith Creek. 9¾ miles above London Bridge. |
| +0·60 | 5 ft. Bl. | Brook Green Sewer. | At Bridge Road, Hammersmith. 9¼ miles above London Bridge |
| −2·90 | 9′ 6″ × 9·0 | Counters Creek | At Cremorne. 5¼ miles above London Bridge. |
| 0·00 | 4′ 0″ × 2·8 | Church Street Sewer. | At Chelsea Embankment. 4¾ miles above London Bridge. |
| 0·00 | 4′ 0″ × 2′ 8″ | Queen Street Sewer. | At Chelsea Embankment. 4¾ miles above London Bridge. |

Sir J. W. Bazalgette, C.B.

11 April 1888.

*North Side.*

| Level. | Size. | Outlet. | Position. |
|---|---|---|---|
| 0·00 | 4′ 0″ × 2·8 | Smith Street Sewer. | At Chelsea Embankment. 4½ miles above London Bridge. |
| −1·20 | 9′ 2″ × 9·6 | Ranelagh Sewer | At Chelsea Embankment. 4 miles above London Bridge. |
| −1·20 | 6′ 9″ Bl. | Western P. S. - | At Pimlico. 3¾ miles above London Bridge. |
| −3·0 | 18′ 0″ × 20·0 | King's Scholars Pond. | At Vauxhall Bridge. 3 miles above London Bridge. |
| −0·7 | 2′ 0″ | Grosvenor Ditch | At Millbank. 2½ miles above London Bridge. |
| −0·2 | 2′ 6″ × 2·0 | Horseferry Road Sewer. | At Millbank Street. 2½ miles above London Bridge. |
| −0·2 | 2′ 6″ × 2·0 | Wood Street Sewer. | At Millbank Street 2½ miles above London Bridge. |
| −8·5 | No. 2 5′ 9″ × 2·9 No. 4 2′ 6″ diam. | Regent and Victoria Street Sewers. | At Charing Cross Bridge. 1½ miles above London Bridge. |

NOTE.—Some of the outlets are larger than the sewers draining to them.

12,729. And all but two are self-acting, are they not?—Yes.

12,730. Then I do not at the present time see what information this table of rainfall which you handed in would give one, beyond what was happening at these particular outfalls?—It would not.

12,731. According to you, the rain and the pressure upon the sewers may be very local in London. You said you could not compare Greenwich and Kew?—No.

12,732. Therefore one thing may be happening at one time in one part of London and a very different thing in another?—Yes; these things happen in different parts of the river at each end of London, and I think may fairly represent what is going on between them.

12,733. As you have put in this diagram, can you tell me what is a quarter of an inch of rainfall upon a square mile in cubic feet?—I cannot give it at the moment, but it would be something very considerable in cubic feet, and on the other hand the amount of absorption and evaporation upon a large surface is very great.

12,734. Now, with regard to the Savoy sewer table; that was a record, if I remember rightly, of how much rain ran off in a period of 36 hours?—Yes.

12,735. There fell 2·90 inches in the 36 hours; do you know at all how that was distributed over the 36 hours, or have you only got what appears on the table?—I have only what appears upon the table.

12,736. You have no means of telling us whether or not it was raining right up to the end of the 36 hours or not?—I believe it was raining continuously.

12,737. I need hardly say that the rain which had fallen within the last half hour or an hour, or even a longer period than that, would not have got to the sewer at all, would it? You would not expect the whole of the water to find its way into the sewerage during the 36 hours?—No, but it would get in rapidly here, because this is a sewer with a rapid falling surface.

12,738. You find in London, do you not, with paved courts and roads and comparatively very little garden ground, that a very much larger proportion of the rainfall finds its way into the sewers than if you deal with another and less urban kind of area?—Yes, undoubtedly.

12,739. Taking the populous parts of London; Park Lane upon the one side, and four or five miles eastward of that upon the other; taking the Thames at the southern boundary, and then going up the Marylebone Road, and taking right through the populous parts; what proportion of rainfall do you think finds its way into the sewers?—If you include the Parks?

12,740. I excluded the Parks on purpose. I take it east of Hyde Park and west of Victoria Park, and bounded by the Thames upon the south?—That being an urban portion, I should think it would behave very much as this area in the table did.

12,741. That not more than 74½ per cent. would find its way to the sewers?—No.

12,742. I mean, taking all the rain, not merely the portion that went off while the rain was falling?—The area drained to the Ratcliffe Highway and the Savoy Street sewers is quite as dense as that; it fairly represents the town area.

12,743. But that was 2·88 inches in the 25 hours, and 300 acres were drained?—Yes.

12,744. But you do not suggest that it all gets off in the 25 hours?—The sewage will not begin running so quickly as the rain begins to fall; it will begin a little later, and continue a little later: you will get it cut off at one end and put on at the other.

12,745. But you will observe, "Total quantities of "rain discharged by the sewer in the above men-"tioned time;" it disregards all that which went off afterwards. Now have you any doubt that a considerable portion of that rain went off afterwards?—Some of it would go off afterwards.

12,746. You stated that the three outfall sewers upon the north side are capable of sending out 33,000 cubic feet per minute?—Yes.

12,747. Would you divide that, if you please, or is it equally divided into high level, low level, and middle level?—In that sewer there are three sewers running parallel with each other, and communicating with each other so that they can relieve each other. They communicate by arches.

12,748. Those are the three pipes which take you from Abbey Mills to Barking?—Yes.

12,749. They are not, as a matter of fact, fed by drains upon the way?—No.

12,750. Then what is there at Abbey Mills which delivers to Abbey Mills?—There are two sewers and the low level sewer.

12,751. All three go to Abbey Mills?—Yes, the low level being 10 feet 3 inches in diameter.

12,752. And how much do they deliver at Abbey Mills?—10,300 cubic feet a minute.

12,753. And the other two?—I think each of them is capable of delivering 11,000 cubic feet a minute.

12,754. If you would rather give me the actual figures, I will postpone the question. Now do they drain equal areas?—No.

*Sir J. W. Bazalgette, C.B.*

11 April 1883.

12,755. It would be convenient, I think, if you could put upon a small map, if possible, the area which is drained upon the north side by the high level, low level, and the middle level sewers?—I have given you that.

12,756. You read some acreages off, but I should be glad to see it upon a map (*exhibiting a map to the witness*). The green colour is the low level?—It is.

12,757. And the blue the middle, and the yellow the hgh level?—It is.

12,758. Am I right in saying that the low level delivers to Abbey Mills with 10 feet 3 inches diameter?—That is right.

12,759. The middle level appears to join the high level at some intermediate point. Is that so, or does it only run parallel?—They run parallel to the river Lea. They join at the river Lea.

12,760. Then I may take it that there is one sewer from that point to the Abbey Mills. Will you tell me what is the diameter of the sewer from the point of unction by the river Lea down to Abbey Mills?—Two nine feet sewers.

12,761. Then the high level, is that a nine feet sewer?—That is 12 feet.

12,762. And the middle level, how much is that?—That is 10 feet 6.

12,763. Does the upper part of the green go into the low level, or is that only accidentally coloured the same colour?—It goes into the low level.

12,764. Will you tell us the proportion of the green as distinguished from the yellow and the blue areas?—I think I can perhaps save you some trouble if I explain to you that the high level sewer is much larger compared to its area and population than the low level. Mr. Baldwin Latham fell into the mistake; he said the population upon the high level sewer is so large that in time of storm it will not be able to take the sewage off.

12,765. What I really want is this, I want the population of the green, the blue, and the yellow approximately?—It will be impossible to get that, except very approximately.

(*Mr. Norman Bazalgette.*) I may state that the next witness who will follow Sir Joseph is prepared to give those figures.

(*Mr. Webster.*) I also want the storm outlet shown with regard to the numbers in those districts.

Adjourned to Tuesday, 1st May, at half past 12 o'clock.

---

# THIRTY-THIRD DAY.

## Tuesday, 22nd May 1883.

PRESENT:

The Right Hon. LORD BRAMWELL, F.R.S., in the Chair.

Sir John Coode, Mem. Inst., C.E.
Colonel C. B. Ewart, C.B., R.E.
Professor Williamson, F.R.S.
François de Chaumont, Esq., M.D., F.R.S.
Thomas Stevenson, Esq., M.D.
James Abernethy, Esq., F.R.S.E., Mem. Inst., C.E.

Wm. Pole, Esq., F.R.S., *Secretary*.

Sir Joseph Bazalgette recalled; further cross-examined by Mr. Webster.

12,766. You were good enough to say upon the last occasion that you would produce some reports in which the effect of the oxidation of the sewage as a deodorising factor was taken into consideration as an element of the scheme?—I did.

12,767. I do not know if it is much to read,—if it is I would ask you to read it afterwards?—Yes, there is a good deal about it in various parts.

*Sir J. W. Bazalgette.*

22 May 1883.

12,768. Then I will ask you to read it afterwards, but I will ask you this question upon it; is it reduced into figures at all as a result?—It is.

12,769. Perhaps you can read the passage in which

*Sir J. W. Bazalgette.*

22 May 1883.

it is so reduced to a result?—It would be difficult to do that, as it is spread over a good deal of the paper.

12,770. I should wish it to be upon the notes, but I will ask you to read it now unless there is one passage in which the result is given in figures, or if you will state the effect or the practical result if arrived at?—The report is the Report of Messrs. Bidder, Hawksley, and Bazalgette, and the date is the 6th of April 1858, and the passages to which I will call attention by-and-bye are contained upon pages 66, 67, 68, 70, 71, and 88 of that Report, and pages 116 and 118 of the Report of Dr. Letheby.

12,771. Of what date?—It is an appendix to the same report.

12,772. Could you now give us without now reading the passages what the effect of it was stated to be, either with respect to the quantities of sewage or time or anything of the kind?—The effect of it is generally that the process of oxidation is taking place in the river, and I think I can give you one result very shortly in Conclusion No. 4 of Dr. Letheby's Report; he says: "This may be obviated by defecting the sewage by "means of lime, and allowing the clear liquor only to "be discharged into the Thames, or by discharging "the sewage into the Thames in such a manner that "it will mix with and be diluted by 200 or 300 times "its bulk of water."

12,773. I think that is the report of the 15th March 1858?—It is.

12,774. The conclusion that you have read from Dr. Letheby's Report commences:—"The mischief "which really results" (I am reading from paragraph 3 of the report) "from the present mode of "disposing the sewage is caused by the insoluble "organic matters which collect upon the banks of the "river near to the sewers, and there undergo per-"petual putrefaction. That this may be obviated by "defecting the sewage by means of lime." That of course has not been done?—No.

12,775. "And allowing the clear liquor only to be "discharged into the Thames, or by discharging the "sewage into the Thames in such a manner that it "will mix with and be diluted by 200 or 300 times "its bulk of water." That means of course that each bulk of sewage will have 200 or 300 times of unpolluted river or sea to mix with?—Yes.

12,776. Have you in any other conclusion as regards the effect of oxidation drawn attention to anything other than that which is stated to be a mixing with water?—Yes. Then I am afraid I must read.

12,777. But have you any other conclusions in figures or time?—I am afraid I cannot give it you shortly.

12,778. Then you shall give it afterwards; now I will draw your attention to a table you put in upon the last occasion, it is to follow Question No. 12,502. Your total area is 50·21 square miles upon the northern side of the Thames, is it not?—That is correct.

12,779. Have you taken that as extracted from the original report which you made?—Yes, except that my Report of 1856 gives the total area as 51·44 square miles.

12,780. Now I will attention to this; it is not a very large difference, but for the purpose of accurate comparison I may want it afterwards. I am told that the summary of the mileage upon the north side in that report is 51·6 square miles.

(*Sir John Coode.*) Does it matter whether it is 51·4 or whether it is 51·6?

12,781. (*Mr. Webster.*) It is not that; I am comparing it with the 50·21; it is a difference of a square mile and a half; it is not very important, but I want to ask Sir Joseph Bazalgette whether he can tell us where the difference occurs (*to the witness*) because you have put in a table showing 50·21?—I cannot say where the difference arises.

12,782. Would you kindly just look through the detail and let us know what the accurate figure is, not for the purpose of showing that anything is wrong but for the purpose of making a comparison with the figures themselves. Now of the 50·21 or of the 51·6 what is the area of the western district. I am told from your own figures that it is 14½ square miles?—That is about it.

12,783. I am told that your 50·21 does not include Acton?—It does not include Acton.

12,784. Will you tell me what is the area of Acton. I am told it is four and a half square miles?—Yes, that is so.

12,785. Then for my purpose these two figures of 14½ square miles of the western district, and the 4½ of Acton are not included?—No.

12,786. You stated upon the last occasion that one of the sewers upon the north side was made 10 feet 3, because you thought that some time or other you might include the western district, are you sure that that was the reason?—Yes.

12,787. That 10 feet three sewer only goes to Abbey Mills, does it; below Abbey Mills there are three 9 feet sewers, are there not?—Yes.

12,788. Then, as a matter of fact, the three sewers from Abbey Mills to the outfall are three 9 feet sewers, while the three sewers down to Abbey Mills are two nines and a 10 foot three?—Yes, that is correct.

12,789. The gradient or the fall is the same, is it not?—Yes.

12,790. What is the difference in cubic feet per minute between what the three nines will take away, as compared with the two nines, and the 10 feet three?—They each discharge 11,000 cubic feet per minute.

12,791. Each of the nine's?—Yes.

12,792. What excess quantity can be brought down to Abbey Mills by the 10 feet three sewer?—The 10 feet three sewer will bring down 14,000 cubic feet per minute, 3,000 more; but the 9 feet sewers above Abbey Mills have a discharging capacity of 3,690 cubic feet per minute in excess of the quantity they were intended to carry; and the flow of all the three 9 feet sewers is limited below Abbey Mills, and they thus become of the right discharging capacity for the duties they were intended to perform.

12,793. These capacities of the 11,000 and the 14,000 are, are they not, assuming the sewers to run full?—Yes, they are.

12,794. Are not the storm outlets placed at a level below that which will admit of the sewers running full?—No, above; at least the weirs are placed so that when the sewers run full they overflow.

12,795. I want to know one way or the other, do I understand you to say that no storm outlet can act until the sewer is running full; is it not the fact that the weir is below the crown of the sewer?—It is.

12,796. How much below, 12 inches?—Generally something like 12 inches.

12,797. Then, as a matter of fact the storm outlets do act when the water or the sewage has risen to within 12 inches of the top?—They begin to act, but they do not prevent its rising to the top and so running full.

12,798. That depends upon the hydrostatic pressure or the water coming down, but what I want to know is, what quantity would be passing out at the storm outlets, assuming the sewer to be running full; can you give us that information in any shape?—No, I cannot.

12,799. By "storm outlets" you mean the outlets which go into the river?—Yes.

12,800. I want to know what quantity would be running out of the storm outlets if your sewer is running full, that is to say, supposing this (*illustrating by a folded sheet of paper*) to be the barrel of the sewer, the storm outlets are a foot below the top, so that the storm outlets would be acting as soon as the sewage rises to within one foot of the top, now the capacity or what the sewer will take away, that is to say, the 14,000 cubic feet a minute, is upon the basis that the sewers are running full, is it not?—Will you permit me to make a correction there? A sewer (though it may seem strange to say it) discharges more when it

is not running quite full than when it is running full.

12,801. Do you mean it is better that there should be an air space at the top?—I mean to say the frictional surface is greater when it is running full than when there is a small space left.

12,802. What would be the discharge when it is running full?—11,000 cubic feet when it is nearly full.

12,803. What would be the discharge capacity when it is running within a foot of the top?—About the same quantity, and if it rose a little higher to within about 9 inches, it would discharge more than if it were running quite full. Mr. Baldwin Latham, I think, adops a formula for discharging his sewer which gives a higher result than I have adopted for mine, but I have taken the same formula for the outfall sewer, and for the discharge of these sewers, and if you take my formula for the discharge of the outfall sewer, you must do the same with the rest, if you add on to one you must add on to the other.

12,804. You called attention upon the last occasion to the large quantity per head going out upon the south side as compared to the north side, I think you spoke of 50 gallons a head?—Forty-six gallons, I think, 46·88 or nearly 47 gallons.

12,805. In the first place in getting at your 47 gallons per head, you assumed, did you not, that the whole of the southern area drained into the Southern outfall?—No, I assumed that the whole of that population residing upon the southern side drained into it.

12,806. That is nearly the same thing, is it not?—Not quite.

(*Chairman.*) I have an impression that Sir Joseph told us that there was a portion of the southern area that was not drained at all.

12,807. (*Mr. Webster.*) I am coming to that directly, my Lord. (*To the witness.*) As a matter of fact there is a considerable strip, is there not, of the southern area between the Southern outfall sewer and the river itself, and also another part of the southern area which is not drained into the river?—There is.

12,808. Would you give us at all approximately with reference either to population or to area, or to anything that would be some guide to us, what part of the 51 square miles or of the population represented thereby, does not drain into the river. I will give you your population if you require it?—According to my calculation there are on the south side altogether, including that which is outside the area, 51·78 square miles drained into the river.

12,809. 51·75 you put it in your table, but never mind that?—Now there are upon the south side altogether 67·78 square miles. Now, I make out that in the marsh lands, the portion of the area draining towards Beckenham away from the metropolis, and Bostal Heath, and commons of that kind there are 6¼ square miles. And there are undrained, the surface waters of which fall into the rivers Quaggy, Ravensbourne, Wandle, and Graveney, and the Beverley Brook about 10 square miles more.

12,810. (*Sir John Coode.*) When you say "undrained" do you mean not sewered?—Not provided with any sewers.

12,811. I think that sum of 16·57 square miles is upon your table?—Yes.

12,812. (*Mr. Webster.*) When you arrived at your 47 gallons a head upon the south side, which you arrived at by calling attention to the tanneries and other things of that kind, which had water in them, what population did you take, did you take the whole of the population upon the 51 square miles?—Yes.

12,813. Is there not in that 51 square miles a very considerable strip of the south side of the river, which drains direct into the river, for instance between Nine Elms and Bermondsey?—No, none at all.

12,814. Then you say it is correct to take the whole of the population of that 51 square miles?—Yes.

12,815. Then I must ask you what population you took when you brought in your 46·88 gallons; in your answer to Question 12,524 you did not say what population you took; did you not then take the entire southern population?—For the 51 square miles I took it as 1,113,000.

12,816. I must go back again to what you said just now; you said that all the drainage along the banks had been diverted to the sewers, but do not you remember telling the Commission the very first day they met that you were advised some three years ago that you, or the district boards, ought to connect all those places with the sewers. Will you just turn to Question 39 with regard to the area undrained or unconnected upon the southern side; you pointed out that there were outfalls draining into the Thames which you had given notice to local boards to divert. Did you mean that what is left now is not worth considering when you said that there is no area which still drains into the Thames between the outfall sewer and the river?—I take that practically is the case, there may be some houses which do.

12,817. Now one question, if you please, upon this; you have accounted for the high quantity of gallons per head discharged upon the south side by referring to the Bermondsey inlets, the tanneries and other such matters; have you got the hourly discharge of that day, the 12th July, 1876, upon which Mr. Baldwin Latham's deductions and your own conclusions were given?—Yes.

12,818. Would you just put it in?—I think that has already been put in.

12,819. I think not; it was upon the Mud Inquiry.

(*Chairman.*) I think this evidence ought to have been given in a different way; it is not as though you were getting facts from a reluctant witness; the facts are agreed upon, and why could not they have been put in a different form which we could all understand.

(*Mr. Webster.*) We suggest that it is leakage into the sewer to a very considerable extent upon the southern side. Sir Joseph Bazalgette comes and says (and we respect his opinion), that he thinks it is due to the tidal water getting in through certain inlets. I can get information which apparently would indicate that it is impossible to account for it in that way, and I need not remind your lordship that it is my duty to put that to Sir Joseph Bazalgette.

(*Chairman.*) Certainly. Do not imagine I am suggesting that you are pursuing a useless inquiry; may I ask what is your object at the present moment.

(*Mr. Webster.*) The first thing is this; the very first sending in of leakage water would have no bad effect, because it would dilute the particular sewage that was going in at the bottom, but it may have, and we believe does have, the effect of choking the sewer with that water low down, so that it is full of water, that it was not intended to carry off, and the result is that the sewage in the upper districts does go into the Thames in a way that is was never intended to go.

(*Chairman.*) Through the storm overflows?

12,820. (*Mr. Webster.*) Through the storm overflows (*To the witness*). Can you tell me at what time of the tide the water is taken in by the Bermondsey inlets?—Do you mean for flushing?

12,821. Not for flushing only, but for the use of these tanneries that you mentioned?—I apprehend that all water taken from the river would be from half tide to high water, and down to half tide again.

12,822. I do not wish for an "apprehension" but do you know as a fact at what time of the tide that water is taken in?—I presume at high water more particularly.

12,823. Could you tell me what would be the total quantity taken in?—I stated it in my evidence in chief.

12,824. That is to say, 4,000,000 gallons in 24 hours?—Yes.

12,825. Does that assume a continuous flow?—No, that assumes that was taken in at the two high waters in the 24 hours.

*Sir J. W. Bazalgette.*

22 May 1883.

12,826. You say 4,000,000 gallons in the two periods of high tide?—Yes, two periods of six hours.

12,827. Can you tell me what times the high tides were upon that day. I will give them to you, 5.18 a.m. and 5.36 p.m. I will ask you to look at this table of the flow, do you suggest that there is any period of the flow in which you could indicate that there was excess water, due to water taken in at the inlets at high tide; will you kindly look at it, from midnight to noon. (*The following Table was handed to the witness.*)

CROSSNESS SEWAGE DISCHARGE.

Hourly Sewage Discharge in dry weather, 12th July 1876. No rainfall from the 24th June to 6th July, on that day, at 8 o'clock, p.m., when 0·16 in. fell, 0·01 in. on the 7th, and 0·02 in. on the 8th.

| Time. | Gallons. | Per cent. | Remarks. |
|---|---|---|---|
| Midnight | | | |
| 0.00 a.m. | | | |
| 1.00 | 1,971,524 | 3·0 | Sewage in main sewer kept at the level of −8·00 throughout the whole time of experiment. |
| 2.00 | 2,198,357 | 4·3 | |
| 3.00 | 1,887,064 | 3·6 | |

(*Mr. Webster to the Chairman.*) This is the particular day, my lord, upon which they gauged; from which the calculation is taken, when you will see 1,971,000 at one o'clock, and 2,198,000 at two o'clock.

(*Chairman.*) What is that?

12,828. (*Mr. Webster.*) Gallons flowing out at Crossness outfall, there having been no rain for the previous 12 days; 3 o'clock 1,877,000 gallons, 4 o'clock 1,940,000 gallons, 5 o'clock, 1,351,000 gallons, 6 o'clock 1,339,000 gallons, and so on (*to the witness*). I suggest to you that there is no fluctuation of any kind, such as would appear if it were due to an abnormal taking in of water at high tide? I do not think I can go with you there.

12,829. Will you tell us at what hour in the first 12 hours, or if you please the first 16 hours that water went in?—It begins with a high flow at about midday.

12,830. What do you mean by the "high-flow" there?—The flow has risen to four or five per cent., 2,800,000, and it continues a high flow until 8 o'clock that evening.

12,831. I should like to know this, and I point it out to you; if I am correct (the dead low water you know, is just before noon); how is that table consistent with the view that the large quantity is due to any tidal influx of water through those inlet pipes twice a day?—I think if you take the distance of these inlets from the outlets, and calculate the time it would take flowing down to the outlets, you will find it has arrived at the outlets somewhere about that period, which shows the high flow.

12,832. I should like you, if you please, if you say that that is what this table shows, kindly to put your inference or your reasoning in the shape of an answer which can appear on the notes?—It wants a little working out, but it does appear to me, looking at the distance of the inlets from the outlets, and the rate of the flow that that is consistent with my theory.

12,833. Do you know whether that was a neap or a flood tide?—I do not know.

12,834. I will tell you that it was a neap tide, but do you know what time, or how long the water could come in upon that day at all?—I did not go into the calculation.

12,835. Will you oblige me by going into it. I suggest to you that this table indicates and proves that your theory of the excess being accounted for by the inlets at Bermondsey and elsewhere cannot be correct; therefore I will ask you kindly to consider it in order that I may not take you by surprise?—I will do so. I think you will find it is consistent with my theory.

12,836. You will remember the time of the tide, and the time of the flow?—Yes.

(*Chairman.*) You suggest that this great discharge is attributable to leakage, while Sir Joseph Bazalgette on the other hand suggests that it is attributable to the inlets of the tanneries.

(*Witness.*) I know as a matter of fact that about one-fourth of the leakage is let in by the tanneries.

13,837. (*Mr. Webster.*) Upon the last occasion you said you could not tell us how much; you said you thought it would be about that?—I put in the report with respect to it.

12,838. But as to the quantity, you said you could not give us the quantity?—I said, I think, that three-fourths of the excess arose from flushing and so on, and one-fourth from the tanneries and factories.

(*Chairman.*) But what I would ask is this. Let it get in from whatever cause it may, would it not equally cause a filling of the sewers.

(*Mr. Webster.*) Certainly, but you know the way in which it was put was, that it was a burden upon the back of the Metropolitan Board of Works, which they could not help, whereas, if it were the sewage that leaked, it was a defect which ought to be remedied quite independent of the rights of any riparian owners or manufacturers.

(*Witness.*) That is not the way in which I put it—the way I put it was, that we flush the sewers only in dry weather when there is a very small flow, and we do not flush the sewers in times when there is heavy rain and when the sewers are likely to be overcharged, and therefore that quantity does not take up the capacity of the sewer at the time when the capacity of the sewer is most likely to be wanted.

12,839. (*Mr. Webster to the witness.*) Now you proposed to tell us, upon the last occasion, upon what area the sewers were calculated to take off a quarter-of-an-inch of rainfall in the 24 hours upon the northern side—in fact upon both sides, and upon what area an eighth of an inch in 24 hours?—That is the calculation that was made in 1856. The calculation then made was to take off a quarter-of-an-inch of rain upon the north side from 28·7 square miles, and an eighth of an inch from 22·8 square miles, or a total of 51·5 square miles. Upon the south side, to take a quarter of an inch from 14·3

square miles, and an eighth of an inch from 28·3 square miles or a total of 42·6 square miles.

12,840. You have given already to-day a capacity of discharge upon the north side of 33,000 cubic feet per minute. That report you referred to contemplated, I think, 20,000 cubic feet per minute as being the capacity of the outfall sewer?—That report left it open.

12,841. But you dealt with it as that, did you not?—Yes, I think at that time we contemplated dealing with the western sewage separately.

12,842. Also did it not contemplate taking in the 4½ miles of Acton?—No, nor do I contemplate taking in the 4½ miles of Acton now.

12,843. Are the 4½ square miles included in your 50, or not?—No.

12,844. Then you have to take away from the 50 square miles only the 14½ square miles of the western district?—Quite so.

12,845. Then the area, less the western district, would, roughly speaking, be 36¾ square miles?—Yes.

12,846. And for that did you, or did you not think at that time that a discharge capacity of 20,000 cubic feet a minute was sufficient?—28,000 was what I thought sufficient.

12,847. Including the western district, or not?—Excluding the western district.

12,848. I think you must be making a mistake there, because I can scarcely understand how 33,000 is to be sufficient if you include the western district?—Because the western district gives about 5,000 cubic feet a minute, I think.

12,849. Do I understand you to say that?—Yes, that is right.

12,850. Do you justify the 33,000 as being sufficient for the present time upon the theory that the western only produces 5,000?—Yes, I do, undoubtedly.

12,851. Do you say that the 33,000 cubic feet per minute has allowed any provision for increase of population upon the old area that was taken in?—Yes.

12,852. How much. You told us on the last occasion that the increase was partly compensated by a more regular or a more extended flow—what part of the 33,000 do you say provides for the increase in the population?—The report of 1856 provided for an increase of population.

12,853. But you do not follow me. You said you thought 28,000 cubic feet per minute discharged from the outfall sewer———

(*Chairman.*) Do you mean a sewer which had a capacity for discharging so much?

(*Mr. Webster.*) Yes, my Lord. (*to the witness.*) Now I ask you—it does not matter how you give the information—what part of that 28,000 cubic feet per minute represented the outfall capacity or power, for increase of population. What margin was there?

(*Chairman.*) As I understand the question is this; how much did you suppose would be discharged from the existing population served by the sewer.

12,854. (*Mr. Webster.*) How much did you suppose would be actually discharged in sewage and rainfall, the population being as it then was?—I did not make that calculation.

12,855. But you have said to us that 28,000 cubic feet per minute was what you thought necessary without the western district.

(*Chairman.*) What he thought would be desirable.

12,856. (*Mr. Webster to the witness.*) Did that take into account the increase of population in that district, or did it not?—It did take into account the increase of the population.

12,857. How much of the 28,000 cubic feet a minute was the discharge capacity which was to meet the increase of population; what did you assume the normal flow would be for the next 12 months?—The population at that time was about 1,600,000, exclusive of the western division, or 1,766,000 with the western division. The population contemplated was 2,056,800 or, with the western division, 2,353,900. Of course I did not go into the calculation how much will it take to carry it now, and how much in the future, but I looked to what it would have to carry in the future and made my provision for that.

12,858. Do I understand you to say that the 28,000 cubic feet a minute were considered desirable for a population of 2,353,900?—Yes, with certain other assumptions which I have given before.

12,859. Then you did not estimate it for the existing population and then add on a margin, but you took it at what would be necessary in the future with the existing population?—Yes, I can give it you in detail.

12,860. (*Chairman.*) It is so clear to my mind that Sir Joseph Bazalgette ought to be able to give an intelligible answer to the question you intended to put, that I cannot understand what the difficulty is. (*To the witness.*) I suppose you reckoned that there would be a certain discharge per head?—Yes.

12,861. What were the number of heads at the time that you made your sewer that were to be served?

(*Mr. Webster.*) Upon the northern side.

(*Witness.*) 1,766,000, including the western division; excluding the western division it is 1,614,000.

12,862. (*Chairman.*) You calculated that they would discharge a certain quantity of sewage?—I did not do that, that was not my object; was to see how large the sewer should be to provide for future generations, and I knew if it would take the larger it would take the lesser, so I did not think it necessary to calculate the lesser.

(*Mr. Webster.*) Your answer is that you considered 28,000 cubic feet a minute was sufficient for 2,353,900.

12,863. (*Chairman.*) You say I will not trouble myself to calculate what is wanted at the present moment, but you said, I will make my sewer big enough for the remainder of the century?—Yes; I thought if the hole was big enough for the cat the kitten could get through.

(*Mr. Webster.*) If you were correct in saying that 28,000 cubic feet a minute was excluding the western district, I had better model all my questions with regard to that excluded district, and will then ask you what population did you take, excluding the western district.

(*Chairman.*) I would rather you asked the witness what population did he suppose would be the maximum population that those sewers would serve.

12,864. (*Sir John Coode.*) If Sir Joseph could give a direct answer to Mr. Webster's question, "How much of that 28,000 cubic feet a minute was "margin for increased population"; we should know all that we require. (*To the witness.*) You say, as I understand, that that 28,000 cubic feet a minute did include a margin; we should like to know how much margin it included?—I cannot give you that without working it out.

(*Sir John Coode.*) I think it would be better to have that than a series of round-about answers, but you can probably tell us to-morrow, of the 28,000 cubic feet, how much was margin for increased population.

(*Witness.*) It is a little complicated to do it in that way, because the rain will be much more constant than the flow of sewage; the population will increase but the area will not.

(*Sir John Coode.*) You can give us the answer to-morrow.

12,865. (*Mr. Webster.*) Just tell me with regard to this what rainfall capacity you did assume in that 28,000 cubic feet a minute, how much rain was it to provide for as well as sewage,—was it the whole of the quarter of an inch and the eighth of an inch?—An eighth of an inch upon eleven square miles, and a quarter of an inch upon twenty-seven square miles.

12,866. But can you tell me what part of your 28,000 cubic feet a minute the rainfall would take up.

(*Chairman.*) I will ask you how long was this eighth of an inch to be falling.

*Sir J. W. Bazalgette.*

22 May 1883.

(*Mr. Webster.*) In twenty-four hours,—the discharge in twenty-four hours of that quantity,—it was the discharge of an eighth of an inch of rainfall falling in that time.

(*Chairman.*) Supposing in twenty-four hours there is an eighth of an inch of rain falling.

12,867. (*Mr. Webster.*) Which has to be got rid of. (*To the witness.*) Now how much of your 28,000 cubic feet would that rainfall occupy?—That rainfall would occupy about half.

12,868. Did you assume that the eighth of an inch would be spread over the twenty-four hours equally, or that was the amount that was to be got rid of, falling during the twenty-four hours at some time or other?—It is that quantity falling at some period in the day and to be got rid of.

12,869. Did you assume it would fall in any given time?—No, I did not.

12,870. (*Chairman.*) I suppose it might all fall in half an hour?—Yes, it might, but I should qualify that by saying, not over the whole area,—if it were to fall in half an hour it would be a thunder shower.

12,871. (*Mr. Bidder.*) Does the eighth of an inch mean a discharge through the sewer equal to an eighth of an inch of rainfall over the area, or does it mean the discharge which might be expected to be produced through the sewers if the eighth of an inch fell over the area?—That is clearly what I do mean, and that represents a great variety of rainfalls under a great variety of circumstances upon areas of different kinds.

12,872. It is the latter that you mean?—It is a provision for an eighth of an inch running off in the sewers divided over the twenty-four hours.

12,873. (*Mr. Webster.*) An eighth of an inch over the whole area?—Yes, an eighth of an inch over the whole area.

12,874. (*Chairman.*) And spread over the whole time?—Yes, spread over the whole time.

12,875. (*Mr. Webster.*) Is it the fact, that the intercepting sewers, as you stated at Question No. 11, were to take the calculated quantity of sewage matter and the quarter of an inch of rain over the whole area?—I was surprised to find I got so much as an eighth of an inch.

12,876. What was the original calculation?—That which I have just given. I stated that at first I provided for a quarter of an inch.

12,877. Now a quarter of an inch in twenty-four hours if spread over the whole time would be roughly $\frac{1}{100}$th of an inch in an hour, and the eighth of an inch would be $\frac{1}{200}$th of an inch in an hour?—Yes.

12,878. Now do you put it that the rain ever does fall as slowly as the $\frac{1}{200}$th of an inch in an hour?—Yes.

12,879. Do you say that from experiment?—Yes, I have put in tables which show that.

12,880. Do you say the tables are already in?—They are, and very elaborate tables.

12,881. You have no other experiments?—You have a good many tables showing that already. I have no others than those I have put in.

12,882. Do you mean put in before this Commission?—Yes.

12,883. Would you kindly show us which the tables are in re-examination?—They are tables at Greenwich and Kew. We have taken out the various rainfalls and their duration.

12,884. I am not saying that by dividing a certain quantity of rain by a certain number of hours, you will not get a certain quantity of rain per hour, but I was asking you whether you suggested that the rain actually falls as slowly as that?—Yes, the tables show that.

12,885. You said you were dealing with 51 square miles of the northern area, and that it must not be assumed that it was always raining over the whole of that area, but I will ask you, have you any record or data as to what portions of the area it does, as a rule, rain over, out of the 51 square miles. I am told that it is exceptional if it does not rain over the whole area, but rains in part only; now have you any data to the contrary?—Yes, the data which are before the Commission. If you take the tables of rainfall at Kew and at Greenwich, it is most remarkable how varied the rainfall is. I have looked at it, and it struck me, when there is a heavy rainfall at Greenwich you will frequently find little or no rainfall at Kew, and *vice versâ*, and in very rare cases do they accord.

12,886. It is a fact is it not, that the rain in the large majority of instances, travels from the west to the east?—Yes, I expect it does.

12,887. If it be a partial rain, or a rain travelling over the area, you will have the rain falling upon the western portion before it falls upon the eastern portion?—Yes, or you may have the clouds discharge themselves in the western portion and not in the eastern,—it may clear up before they have reached the east,—they may have emptied themselves.

12,888. Now I will ask you whether or not, you think there would be any effect due to the way in which the rain passes from west to east as distinguished from the other direction,—would it not have a tendency to put a greater strain upon the sewers in the one case than the other, due to the outfall portion being congested by the rain which had previously fallen upon the western portion?—I do not think that.

12,889. At Question 12,519 you corrected Mr. Baldwin Latham's answer by saying that he had drawn a wrong deduction, because the western district sewage had not been taken off at Barking in the years 1875 and 1876; you are accurate about that?—Yes.

12,890. Is not it the fact that the western pumping station was opened in August 1875?—Yes.

12,891. Was not it taking in the western sewage after August 1875, and all through 1876?—No, the low level western sewers were not completed until April 1876, although the pumping station was completed in 1875.

12,892. I find by the Report of the Metropolitan Board of Works of the 31st December 1875, "The "western part of the low-level sewer and the pumping "station were completed and publicly opened by the "Chairman of the Board on the 5th of August last. "At this station the sewage from the low lying "western portions of the metropolis is lifted a height "of 18 feet into the low level sewer, which runs from "this point to the pumping station at Abbey Mills, "West Ham"?—Then you are incorrectly informed, or I am.

12,893. No portion of the western sewage was running then?—Yes, some portion of it.

12,894. But you suggested in your answer that the western sewage had not been diverted to Barking in the years 1875 and 1876?—I say a very small portion of the western district sewage was.

12,895. And "This year has witnessed the com- "pletion of the western portion of the Northern Low "Level Sewer, and of the pumping station in Gros- "venor Road, Pimlico, which were the only parts of "the system of main drainage unfinished at the "beginning of the year, with the exception of certain "works incidental to the main system for intercepting "the sewage from small areas in the City of London, "Wapping, and North Woolwich." What quantity do you say was coming in in 1876?—I can only give you the quantity shown by the discharge at Barking.

12,896. But you say only a small portion was coming in in 1875 and 1876; what portion?—I cannot tell you that off-hand.

12,897. I should like to know, because you criticised Mr. Latham's deduction which says, that it was going in, while you say that none of it had been diverted at that time; cannot you tell me how much of it was going in at that time?—I cannot offhand, but I will endeavour to find it.

12,898. You were going to give us a table of the dates when the storm overflows acted; have you got that?—You mean at the outfalls?

12,899. Wherever they are.—I put in a table of storm overflows as regards the sewers.

12,900. But you were to give us the dates when the waters ran out at the storm overflows?—I have given you that.

12,901. I do not think you have; you gave us the number at the time?—I told you I could not give you particulars with regard to the storm overflows, excepting at Deptford Creek.

Re-examined by Mr. Norman Bazalgette.

12,902. I will ask you first of all this,—at Question 12,631, you were asked, "What did you assume, then, "was the period during which or over which this "oscillating action might take place, as distinguished "from the space in which it would take place"; have you got a report which you made, dated 3rd April 1856?—Yes, I describe that action at pages 8, 9, and 10 of my Report of the 3rd April 1856.

12,903. What did you in that Report assume the period was in which the oscillating action would take place?—I then reported, "With regard to the point "of discharge, I cannot do better than quote from "the Report of Mr. Stephenson and Sir William "Cubitt, dated the 11th December 1854, wherein "they give the following brief summary of a series "of experiments made by the late Mr. Frank Foster "upon this subject, 'On the 15th July 1851, a float "'was put into the centre of the river opposite "'Barking Creek two hours after high water. This "'time was chosen because it was found that sewage "'discharged into the river two hours before high "'water arrived at about the same point above "'Barking Creek that sewage discharged two hours "'after high-water did by the next flood tide. At "'low water it reached 11¾ miles below that point, "'and returned with the next flood tide to one mile "'above it, having gone 12¾ miles that flood, it being "'then the period of spring tides. As the neaps "'came on, the float continued to work lower down "'each succeeding high water, and by the 24th "'July it was 13 miles below Barking Creek at high "'water, having gone down the river 14 miles dur-"'ing the falling off of spring tides to neap tides. "'As the flood again became stronger it worked up "'the river each succeeding tide until the 29th of "'July, when it again came within five miles below "'Barking Creek at high water, having worked up "'the river nine miles from high water neap tides "'to high water spring tides; the excess of the ebbs "'over the floods being only five miles in 14 days. "'Another experiment was tried at the same place "'on 6th of August 1851, it being then lowest neaps "'and the float being put down two hours after high "'water. It worked up each succeeding high water "'till top springs on the 12th of August, when it "'reached 6¼ miles above Barking Creek at high "'water. The float then again worked down the "'river till the 20th August being neaps, when at "'high water it reached 9½ miles below Barking "'Creek, being a distance of 16 miles during the "'falling off of spring tides to neap tides. The "'excess of ebbs over the floods would, in this case, "'have been about 7 miles in 14 days. The wind "'and other causes would vary the result, but it "'may be roughly assumed that a substance in "'suspension works up the river about one mile a "'day each high water as the springs strengthen, "'and down the river two miles a day as they fall "'off. The main object was, of course, to determine "'how near to London the sewage could be dis-"'charged into the river at or near high water "'without finding its way back again to the in-"'habited part of the town. The experiments prove "'that it was essential to go as far as Barking Creek, "'and also, as regards the level of the discharge they "'demonstrated that it should take place at or as "'near high water as practicable.' Now, although "it is desirable to fix the place of discharge as far "below the metropolis as possible, it will be found "that a practical limit to it is imposed by the neces-"sity of maintaining sufficient fall in the sewers to "keep them clean, and at the same time of pre-"serving as a safety valve, a discharge into the river "at low water by gravitation in case of accident to "the pumps as well as during excessive floods. It "must be borne in mind 'that the delivery of the "'sewage at high water into the river at any point "'is equivalent to its discharge at low water at a "'point 12 miles lower down the river, therefore, the "'construction of 12 miles of sewer is saved by dis-"'charging the sewage at high instead of at low "'water.' The position selected is Plumstead "Marshes, and the period of discharging the sewage "into the river would be from two to four hours "nearest to high water. The amount of sewage pro-"posed to be intercepted from the more closely in-"habited districts has been estimated upon data, "which makes provision for the increase of future "generations. Thus, where the population as at "present existing exceeds 30,000 to the square mile, "the actual numbers are estimated for, and where it "is less, allowance has been made for that number, in "order to provide for future increase. The supply "of water per head has been reckoned at five cubic "feet per diem, being on a more liberal scale than "now actually obtains, and of this quantity it is con-"templated that one-half will pass away during six "hours of the day. For reasons more fully set forth "in former reports, it is proposed in the urban dis-"tricts to intercept a quantity equal to a quarter of "an inch of rain in 24 hours running off, which is at "the rate of about one hundredth part of an inch per "hour, any excess beyond that amount falling on "occasions of heavy storms being discharged into the "river by the drainage sewers. With a view to "economy by the reduction of the sizes of the sewers "as far as practicable, it is now proposed to continue "the drainage of all those portions of the suburbs "which are not likely to be built upon for many "years to come into their natural valley outfalls, and "where building has already commenced, and is "likely to be extended to provide for an increase of "population, varying from 10,000 to 20,000 to the "square mile, instead of 30,000. It is further pro-"posed from the more thinly peopled suburbs to "carry off by the intercepting sewers only one half "of the quantity of rain water for which provision is "made in the more crowded districts."

12,904. Then, as a matter of fact, in that report of 1856, you considered both the range and the period of oscillation?—We did.

12,905. Now I will go to Question 12,637, in which "you were asked "I should like you to tell me if you "could of any report in which you have dealt with "the question of dilution and oxidation prior to this "Commission" to which you replied "I will ask "leave to produce them by-and-bye;" can you pro-duce them now?—Yes, in the Report of Messrs. Bidder, Hawksley, and Bazalgette, dated April 6th 1858, on page 66 this is stated: "For the proper "understanding of the reasons for our final recom-"mendations, it is necessary that we should draw the "especial attention of the board to the results of the "investigation we have caused to be instituted by "Dr. Letheby, to whom (on account of his eminence "in chemistry, his knowledge of medicine, and the "personal interest he has taken as the medical officer "of the city of London, in all that concerns the "health of the metropolis) we have thought it right "to commit the hygienic portion of our inquiry. We "have also considered Dr. Letheby not the less fit to "assist us, because he commenced the investigation "under the known influence of casually acquired pre-"possessions, adverse to some of the views to which

*Sir J. W. Bazalgette.*

22 May 1883.

" we had been led by our own observations on tidal " rivers, made in many previous years, and in many " parts of England and the continent, as well as upon " the River Thames during the period in which its " physical condition has become the subject of public " complaint. From the results of our own practice " and experience in hydraulic engineering, and par- " ticularly in reference to the drainage of towns and " the utilization of the products of sewage, we have " long been aware of the important fact that those " organic matters which are commonly received from " the domestic drains into the street sewers, and are " there acted upon by water and air undergo changes " and decompositions not necessarily of a putrefactive " character, but in the course of which they either " become resolved into their original elements or " become combined into new forms essentially differ- " ent from those in which they had originally " existed. These changes are effected with great " rapidity, so much so indeed, that it is rare to find " in the waters discharged from the sewers of a large " town any of those rich fertilising agents it has been " the object of so many endeavours to obtain; " fertilising agents of a class which, if they could " continue to exist and act in combination with " flowing water as they observedly exist, under other " circumstances would engender nuisances of a cha- " racter most prejudicial to health and intolerable to " the senses. The elements of the organic com- " pounds which are found in the excreta of towns are " all essentially pure and inocuous. It is only the " condition and proportion in which they become " united in effete matter that communicates to such " matter its disagreeable, or it may be poisonous, " properties. Sulphuretted hydrogen is a deadly gas " largely evolved from excrementitious matter whilst " passing through the process of putrefactive decom- " position. But hydrogen, one of the two elements " of this deadly gas, constitutes a ninth part by " weight of the water we not only drink with " impunity, but know to be in a thousand ways " essential to animal and vegetable life; whilst " sulphur, the other element, is in its natural state a " perfectly inert substance, incapable by its presence " of producing any injurious effect on the vital " economy. So hydrogen and nitrogen, the latter a " gas which constitutes four-fifths of the atmosphere " we breathe, and both of them inodorous, combine " together to form ammonia, the pungent basis of " many of our most valuable manures, and this again, " in union with sulphuretted hydrogen, is a most " noisome emanation from the fæcal matter trans- " mitted to the sewers. If the excreta then could " continue to exist as such, and could undergo the " same process of putrefactive decomposition after " being conveyed into the drains, as we know would " otherwise result, our sewers and rivers would on " the one hand, have long since become cesspools of " the most offensive and deadly description, while on " the other hand, the manufacturers of fertilising " compounds would have experienced no difficulty in " recovering the rich products of animal existence " for which they have hitherto sought in vain. We " feel assured, however, from the facts before us, " that so soon as the refuse of life has become " thoroughly blended with water, chemical changes " of the most important character become gradually " effected by the oxygenation (*without putrefaction*) " of some, if not of all, the combustible elements, and " the consequent decomposition and arrangement of " the other elements into inorganic forms nowise " injurious to the health of animated beings. Hence " it is that the substances which enter into a " sewer are either not to be found at its mouth, or " are only to be there obtained in a much altered and " scarcely recognisable form. And hence, too, it is " that the admission of foul organic matters into our " streams and rivers fails to render them permanently " impure or sensibly injurious. This beneficient " process of nature is indeed gradual, and to a " certain extent undoubtedly dependent on the " volume and the quality of the water into which the " dejecta are received. Observation, however, has " satisfied us that when sewage water of ordinary " strength becomes intermixed in a flowing stream " with 10 or 12 times its own volume of fresh or " freshened water, it ceases to have any tendency to " run into putrefactive decomposition, and is finally " 'consumed' by the oxygen with which one or " more of its elements enter into purifying combina- " tion. We have examined the River Mersey, which " flows from Manchester, Stockport, Bolton, Bury, " Rochdale, Oldham, and numerous other of the " important manufacturing and densely populated " towns of Lancashire and Cheshire; the River Aire, " which flows from Leeds, Bradford, Halifax, Hud- " dersfield, and other towns of the West Yorkshire " manufacturing district; the River Don, which " flows from the crowded towns of Sheffield and " Rotherham, and yet becomes pure enough to be " drank at Doncaster; the River Soar, which for- " merly quitted Leicester of inky blackness, and yet " became beautifully pellucid and full of fish and " vegetation before its arrival at Loughborough; and " in all these instances we have remarked with " wonder the rapidity of the oxidizing process by " which nature causes the disgusting feculæ of towns " to become resolved into pure and inoffensive sub- " stances. The valuable analytical researches contri- " buted to the Referees' Report by Dr. Hofmann and " Mr. Witt, afford scientific evidence of the accuracy " of the conclusions derived from the study of the " phenomena of observation. At page 8 of their " Report, the referees with another object compile " from the results of Dr. Hofmann and Mr. Witt, " the following remarkable table exhibiting the con- " dition of the river at six places, commencing at " Kew Bridge *above* London, and terminating at the " Victoria Docks *below* London." Then the table gives the organic and mineral compounds at Kew in river water to be nearly 25—24·9 grains per gallon; at Fulham, 22; at Wandsworth, 26; at Westminster Bridge, 25½; at London Bridge, 25·8; at Victoria Docks, 27; the mean being 25 grains per gallon. Then the Report proceeds:—" Now from this table " it is manifest that the organic matter nowhere much " exceeds 2 grains in a gallon = $\frac{1}{3500}$th, and that " it is of nearly the same amount in all parts of the " river between the points named, at London Bridge " as at Kew; this amount being in itself very small " and scarcely in excess of the quantity of organic " matter to be found in the waters of nearly all tidal " rivers, and in many non-tidal rivers, whether flowing " from peopled or uninhabited districts." " Dr. Taylor " the eminent analytical chemist, in his examination " before a Committee of the House of Commons on " the Metropolis Water Supply."

(*Chairman to Mr. Norman Bazalgette.*) Does not this, which has been already read by Sir Joseph Bazalgette, sufficiently answer your question?

(*Mr. Norman Bazalgette.*) The object of the cross-examination was to show that Sir Joseph had not sufficiently considered these questions before he designed the main drainage.

(*Chairman.*) But does not this extract show abundantly that he did consider it?

(*Witness.*) There is very little more to read.

12,906. (*Mr. Norman Bazalgette.*) Will you go to the conclusion?—I will. " Our own experience had " informed us not only that it is extremely undesir- " able in a sanitary point of view to cause sewage " matter to become intermixed with sea water, and " especially under circumstances which will occasion " it to be brought up the river by the flood tide, but " that if the sewage matter were poured into a " much larger volume of fresh or freshened water " in a flowing stream, it would become immediately " oxygenized and cease to exist as a noisome and " offensive agent. The experiments of Dr. Letheby " and Dr. Odling have fully confirmed our views. " We have therefore unhesitatingly selected for recom- " mendation as points of outfall, places situated in

" approachable situations as near as possible to the " metropolitan boundary and as far as possible from " human habitations. Barking Creek on the north " side, and Crossness Point on the south side, fulfil " all the favourable conditions that are attainable " on either side of the river. Both are situated in " low and dreary marshes where neither the works " nor the sewage can give reasonable cause of offence " to anyone. Barking Creek is about 2 miles from " Woolwich and about 4½ miles from Erith. Cross- " ness Point is midway between the two places and " about 3¼ miles from each. The mean sectional " area of the river at these places is four times as " great as at London Bridge, and the average volume " of tidal water about 400 times as much as the " volume of the sewage water to be admitted into " it. The river is fresh, or nearly so, at low water, " and only moderately mixed with salts of marine " origin at high water, more so, it is true, than we " could wish, but much less so than at any point " lower down the river."

12,907. Now, you have told us that in coming to these conclusions you were also guided by the report of Dr. Letheby, which is contained in the appendix to your report; his conclusions are contained on page 116?—Yes. He says, " As an example of the " injurious effect of this mud on one hand, and of " the rapidity with which the soluble organic matter " of the Thames becomes inocuous on the other, I " may mention that in the course of my inquiries " into the state of the water in the docks of London " I have remarked that all the docks on the northern " side of the river which receive their water from " the Thames below Blackwall are never offensive. " It may be that they are not so crowded with ship- " ping as the London and St. Katherine's Docks, and " therefore do not receive so large an amount of " putrescible matter; but, be this as it may, the " water in both of the last-named docks is always " turbid, and in the summer time is offensive, from " the putrefaction of the mud. All organic life has " long since disappeared from it, except perhaps the " infusorial life which swarms everywhere. It is " not so, however, with the docks lower down the " river. At the West India Dock, which comes next " in the course of the stream, the water is compara- " tively pure, and it is generally well stocked with " fish. In the summer time, however, the mud even " there undergoes putrefaction, and kills the fish. " At the East India Docks the water is still purer, " and it is a rare circumstance for the mud to putrefy " and the fish to be killed, while at the Victoria " Docks the water is as clear as it need be, and fish " of all kinds are abundant in it. The mud never " decomposes, nor does the water ever show the least " sign of putrefaction. Now, in all these cases the " supply of water is from the river at certain periods " of the flowing tide, and it would appear that if the " organic matter of the soluble or insoluble part of " the London sewage is the cause of the mischief " observed in the London and St. Katherine's Docks, " this matter is completely inocuous by the time the " water containihg it reaches Blackwall. It is not " that the proportion of the organic matter decreases, " as will be seen by the tables, but its condition is " altered. This is, no doubt, occasioned by the " action of the air, and by the agitation of the run- " ning stream, and the fact is amply demonstrated " in every river in the kingdom, especially in those " which receive the sewage of large towns. Those, " therefore, who have looked upon the soluble sewage " of London as an unchangeable log of wood floating " up and down the river with the movements of the " tide, have taken a very erroneous view of the " thing, for so prone is the organic matter to undergo " change and to complete its course of putrefaction, " that it is doubtful if it exists as a putrefying body " a few hours after its entrance into the river. In " fact, while it has been traversing the sewers it has " generally been so much agitated and broken up by " the movements of the current as to be in a very " advanced state of putrefaction. Almost the whole " of the nitrogen has become changed into ammonia, " and its sulphur into sulphuretted hydrogen, and " then, when it reaches the Thames, it finishes the " last stage of its putrefactive career by the rapid " absorption of oxygen, and the formation of com- " pounds that are comparatively inert, so that, partly " by means of dilution and partly by the destructive " powers of oxidation, the Thames possesses the " means of self purification, which is fully equal to " the contaminating injury to which it is at present " exposed." And Dr. Letheby concluded his report by saying, " I am even of opinion that the discharge " of the sewage into the river in such a way that it " would be diluted with not less than 200 or 300 " times its bulk of water during each tide, and in such " a manner that the insoluble portions would not be " deposited on the banks, would be a safe and suffi- " cient means of disposing of it."

12,908. Now I will ask you one question upon that. My learned friend, Mr. Webster, this morning put it to you that 200 or 300 times its bulk was unpolluted water; was Dr. Letheby, when he wrote that, speaking of its dilution with Thames water?—Yes; his fourth conclusion is, " or by discharging the " sewage into the Thames in such a manner that it " will mix with and be diluted by 200 or 300 times " its bulk of water."

12,909. (*Sir John Coode.*) That is water fresh and tidal?—Yes, that is water which is in the Thames; he alludes to the Thames specially.

12,910. The proportion of fresh and tidal varying according to the hour of the day?—Yes.

(*Chairman.*) Will you allow me to ask you this, if the sewage goes up the river above Barking, and then you discharge into the mixture, and then that goes up, and then you discharge again into the mixture, and so on (I am not arguing the point), can that be said to be discharging into 200 times its volume of " water," the first discharge would be so, no doubt, but on the second occasion you would, would you not, be discharging into the mixture?

(*Mr. Bidder.*) Would that not depend, my Lord, upon whether the first discharge had or had not been got rid of?

(*Witness.*) If you take Dr. Letheby's report, you will see he shows that this process of oxidation goes on with great rapidity.

12,911. (*Chairman.*) Do not suppose I am arguing, I know nothing about it, but take it that you discharge at the beginning of the springs, some of that discharge as I understand it, will be carried above the point of discharge at the next high water, then you discharge into the mixture which is worse than it was before, and then some of that will be above the outlet at the next high water, then you discharge into that worse mixture, and so on; do you see what I mean?—I hope before the inquiry is finished to show that that sewage which was discharged is not a mixture, but has been destroyed, and has ceased to exist before the additional sewage was cast in.

12,912. (*Sir John Coode.*) That is to say the sewage which was discharged yesterday is not sewage to-day?—That taking the sewage which is discharged into the river each day, the water which comes in from the sea on one tide is sufficient to oxidize each day what is coming down that day.

12,913. (*Mr. Norman Bazelgette.*) Taking the population at the present time and the water supply, and the average discharge upon an ordinary ebb tide, what is the amount of dilution at the present moment?—Taking Mr. Baldwin Latham's estimate of the popu- lation for this year, 1883, and multiplying it by the water supply, we have 9,690,000 cubic feet of sewage discharged daily into two ebb tides containing 2,233 million cubic feet of water.

12,914. (*Sir John Coode.*) Is that at neap or at spring tides?—At mean tides. Nine millions divided into 2,233 millions gives you in round numbers a didution of 1 in 230, so that we have complied with

*Sir J. W. Bazalgette.*

22 May 1883.

what Dr. Letheby said was the proper amount of dilution to effect purification.

12,915. (*Mr. Abernethy.*) That calculation is all based upon an ebb tide?—Yes, upon an ebb tide.

12,916. (*Mr. Norman Bazalgette.*) I will go next to Questions 12,644 and 12,645, my learned friend Mr. Webster, speaking of oxidation, says—"But to "what extent it would operate you do not recollect. "whether it was put down as a question of time or "volume," and your answer was—"It was both. "(*Q.*) I know in general terms, but taking the "volume you had to deal with, to what extent. "(*A.*) Speaking from this distance of time I cannot "give you the figures," I believe by reference to Dr. Letheby's Report you can give us the figures, it is at page 116 in the Report you have just read. I think you will find the answer there?—That I think I have answered already by quoting Dr. Letheby's Report.

12,917. Then we will pass on to Questions 12,647 and 12,648. "(*Q.*) And having gone into it in that "way I should be glad to see any report which would "embody the effect of your inspection. Did you at "all deal with the question of the solid matter. I "have no doubt you did. (*A.*) We did. (*Q.*) Did "you form an opinion as to what were the solid con- "stituent parts of the sewage going into the Thames. "(*A.*) Yes." You are going to read us the opinion you formed as to the solid constituents of the sewage going into the Thames?—At page 74 we reported, as follows: "In considering the causes of the turbidity "of the Thames it should be remembered that the "amount of solid matter of every description which "is poured into the Thames by the London sewers is "a comparatively insignificant quantity, certainly not "greater than 250 tons a day, a quantity scarcely "scarcely exceeding that which is cleared out of the "docks by manual labour only. The mud incident "to the Thames as a tidal estuary is largely in excess "of the mud projected into the Thames by any "population on its banks; the former is permanent, "whilst the latter is perpetually undergoing destruc- "tive decomposition. Supposing, however, as an "extreme illustration, that the sewage mud is in- "destructible and that it takes 50 days to escape to "Gravesend, it would there find itself intermixed "with a volume of water no less in quantity than "250 millions of tons, so that only one-20,000th part "of solid matter (*i.e.*, 12,500 tons in 250,000,000 "tons) would at the expiration of 50 days become "intermixed with the river water between London "Bridge and Gravesend, or (supposing that there "were neither deposit nor decomposition) 2 ounces "of insoluble matter would remain in a ton of "water. Nothing, therefore, can be more erroneous "than to suppose that the opacity of the river is "an indication either of its unsanitary state or of a "condition produced by the admission of sewage "mud. The experiments of Messrs. Hofmann and "Witt, relied upon by the referees, demonstrate "that the Thames at Kew Bridge contains as much "organic matter as the Thames at London Bridge, "although everyone may observe that the water at "Kew is nevertheless much clearer than in London. "In many rivers besides the Thames (the Nile for "one example, the Humber for another, and the "Elbe for a third) whilst the opacity is excessive, "the chemical purity of the upland water is attested "both by experiment and use." Now at that time we calculated the solid matter at 250 tons a day.

12,918. Was that for the then population?—No, prospectively.

12,919. Dr. Tidy, I think, put it for a population of 4,000,000 at the present time at 294 tons?—Dr. Tidy, in answer to questions 10,422 and 10,437, for a population of 4,000,000, estimated the dry matter in fæces at 97 tons per day, and the urine at 197, or 294 tons a day altogether, that would have been a little in excess of our estimate, if you take the dry matter in urine as forming a solid deposit. Messrs. Bazalgette, Law, and Chatterton, in their Report upon the Thames, of the 15th April 1878, estimated the total solid matter discharged into the River Thames from 120,000,000 gallons of sewage, assuming 23 grains of solid matter to the gallon at 176 tons per day. Dr. Tidy, in answer to question 10,342, gives from 23 to 25 grains per gallon as the quantity of solid matter in normal sewage, showing that our estimate of the 250 tons was in excess.

12,920. (*Sir John Coode.*) When you spoke just now of prospective population, may I ask prospective for how long; you calculated, I suppose, a certain increase of population over a certain period—what was that period?—The population that we looked forward to was 3,500,000.

12,921. Taking both sides?—Yes.

12,922. And it was at that time how much?—I think about 2,500,000.

12,923. (*Mr. Norman Bazalgette.*) I think you told us the other day, that in consequence of the more even distribution of the sewage which you discovered from subsequent experiments takes place, you find you have room for a larger population than you anticipated at that time?—We have. A great deal of my cross-examination has been tending to show that the intercepting sewers are not sufficient, that the population has increased, so that they have now become too small. That is not the fact. On the contrary the intercepting sewers are not filled with sewage to the extent that we contemplated; for although the population has now exceeded what we contemplated, the rate of flow is so much more equalised that the quantity flowing in them does not come up to what we provided for.

12,924. (*Sir John Coode.*) What ratio does the one bear to the other?—I am just going to show you.

12,925. Did you not explain this to us before?—I think not. I am now going to tell you what has happened since we last met. We have three outfall sewers upon the north side, which take the whole of the sewage of the north side, and our estimate was, that when our maximum was attained, with a maximum flow of sewage, those three sewers would be half filled with sewage, that is to say, the sewers from Abbey Mills to the outfall. Now I am going to give you a fact that will be better than all the theories and reasonings upon which we might spend the day. My calculations, as I say, showed that these three sewers during the time of maximum flow should be half filled with sewage, and the other half should be left for the quarter or eighth of an inch of rain. I took the maximum flow of sewage to be double the rate of ordinary flow, but it is not that I said, if you double the rate of ordinary flow.

12,926. (*Chairman.*) By "ordinary" do you mean "average"?—Yes, the average. If you double the average flow at a certain period of the day, during that period my sewers would be running half full; that was what I believed would be the case, but upon the 15th, and from the 15th to the 19th of this present month of May, I had occasion to divert the sewage from one of these three outfall sewers, and to let two sewers do the duty of the three, and I for those days carefully watched what was the highest point to which the sewage rose; it was dry weather, it must be remembered. I turned the high level into the middle level, and when the two supplies were going through one sewer, it rose, (the sewer being 9 feet high) to 5 feet 2 at the maximum, and it rose in the other—there is some communication which equalised it a little, but not altogether, to 3 feet 10. Now the quantity flowing through those two sewers at the time, instead of being half, was only one-third, of what the sewers could carry off, in fact, I could now put the whole of the sewage of the north of London into one of those three sewers, and it would carry the whole away, and I have two-thirds of my capacity left instead of a half as I contemplated.

12,927. (*Mr. Lumley Smith.*) That is assuming no rain?—Yes, assuming no rain. As I said I contemplated the sewage running probably about 2 feet 6 at the bottom of this 9 foot sewer ordinarily,

but at the maximum flow I contemplated its rising up to fill them half fall; it does not do so, it only rises up to fill them one-third, and the consequence is I have two-thirds still left for increase of population and rain; and these sewers are large enough to last, at any rate, to the end of the present century.

12,928. (*Mr. Norman Bazalgette.*) Now I will go to question 12,668 where my learned friend Mr. Webster puts it to you in this way, "Now will you "give us in the shape of a table, or some how or "other, how often, or over what period, sewage has "been discharged from the high level, and the lower "level, that is to say, from the northern and the "southern outfalls respectively, after high water," to which you replied "We have discharged up to four "hours after high water, and sometimes we have "been obliged to discharge before the beginning of "ebb tide, that is to say, in a flood, when you have "heavy rains." And then at question 12,697 you were asked, "I am afraid I want it a little more in "detail if you will give it me. I presume a record is "kept of the discharge?—(*A.*) Yes. (*Q.*) There "can be no difficulty in putting in a tabulated statement "for, say, the last eight years, the hours of the out-"pouring or letting out of the sewage upon the north "side, and the south side respectively?—(*A.*) I do "not think there would be any difficulty about that. "(*Q.*) Would you also kindly show upon that table "the instances in which it began before high water, "and of course, the duration of it; in all other cases "I presume it began at high water?—(*A.*) Yes." Have you now got such a table?—Yes, I have. I now put in that table, and I should like, in putting it in, to give some explanation of it. (*The witness handed in the following table*).

TABLE A.

TABLE showing NUMBER of DAYS on which OVERFLOW before HIGH WATER occurred, and their duration at CROSSNESS RESERVOIR, in consequence of the insufficient Size of the Reservoir or Heavy Rainfalls, from 1875 to 1882, inclusive.

| Years. | Number of Days on which Overflows occurred. | Duration. |
|---|---|---|
| 1875 | 144 | 14 days. |
| 1876 | 135 | 11 „ |
| 1877 | 234 | 20 „ |
| 1878 | 253 | 22 „ |
| 1879 | 290 | 31 „ |
| 1880 | 195 | 15 „ |
| 1881 | 192 | 12 „ |
| 1882 | 153 | 9 „ |

From 1875 to 1879, inclusive, the sewage was discharged for three hours, and subsequently for four hours, after high-water.

TABLE B.

TABLE showing NUMBER of DAYS on which OVERFLOWS before HIGH WATER occurred, and their duration at BARKING CREEK RESERVOIRS, in consequence of the insufficient Size of the Reservoirs or Heavy Rainfalls, from 1875 to 1882, inclusive.

| Years. | Number of Days on which Overflows occurred. | Duration. |
|---|---|---|
| 1875 | 78 | 10 days. |
| 1876 | 77 | 10 „ |
| 1877 | 144 | 17 „ |
| 1878 | 157 | 18 „ |
| 1879 | 258 | 33 „ |
| 1880 | 212 | 27 „ |
| 1881 | 244 | 27 „ |
| 1882 | 223 | 29 „ |

The discharge of sewage on the ebb tide varied from three hours in 1875 to four hours in 1882.

(*Witness.*) The above table thows that on the south side the number of occasions on which overflows took place upon the flood tide owing to the reservoir being too small, and from rain, varied from 135 days up to 290 days.

12,929. (*Sir John Coode.*) Are those overflows from the reservoir, or from the outlets?—Those are overflows from Crossness reservoir upon the flood tide. You can judge of the periods, or the length of time, by seeing how many days of 24 hours it works out into; this shows the number of actual days and calculated days of 24 hours each.

12,930. (*Chairman.*) An overflow before high water occurred on 144 days and lasted during 336 hours?—That was in the year 1875, equal to 14 days of 24 hours. Now upon the north side it was doing it on fewer occasions but for a longer period.

12,931. (*Sir John Coode.*) Before you leave the south side, we all know that 1882 was a wet year, and how does it happen that the overflows were only at work for nine estimated days?—It puzzled me at first, and I will explain it. I discovered that by seeing that if you take the north side, that is not so; that I was very much struck with myself, but if you turn to my table of the discharge at the Deptford Creek, you will find that I have to give you an account of an excessive discharge at Deptford Creek. At Deptford Creek in 1881 and 1882 it jumped up from 21 to 36, 37, and 39, for reasons which I have to explain to you. It is quite clear that you cannot have it at both places,—we let it out at Deptford Creek, therefore there was less went down to Crossness,—that is the explanation, though it puzzled me at first.

12,932. (*Chairman.*) But allow me to suggest that you get out of one trouble into another; because it is much worse for you to discharge your sewage at Deptford Creek than at Crossness?—Yes; but I explained how we discharged at Deptford Creek,—we had had an action brought against us, and I mentioned that our man there let it out improperly. Then another question asked me was, for how long we discharged; we had been discharging upon the north side for four hours, and upon the south side only for three hours, and within the last year or two I gave the order that both should discharge till four hours after high water, and we are now discharging up to four hours after high water until we get our reservoirs enlarged, so as not to have so many overflows as we have had upon the south side before the period of high water.

12,933. (*Sir John Coode.*) Then you have ceased discharging at two hours below low water?—Yes, we have until we get our new reservoir.

12,934. But how long has that been so?—Upon the northern side it has been so for years, and upon the south side since 1879.

12,935. How are we to reconcile that with the statements which have been made to us about the discharge having been seen to be going on just immediately before high water. I think we were told, on one occasion, an hour before high water?—Those are the occasions given in this table.

12,936. That was because of the overflow?—Yes, our reservoirs not being large enough.

12,937. That is the explanation of the sewage having been seen to be flowing into the river just before high water?—Yes.

12,938. (*Mr. Lumley Smith.*) But we have no return of the number of times or hours upon which the flow has gone on after the four hours?—At no time after the four hours; always at the end of the four hours we have closed the penstocks.

12,939. (*Sir John Coode.*) That has been the order, but has that been done?—It has been done; there was a leakage at the Barking Outfall, but as soon as we discovered it we remedied it.

12,940. (*Mr. Norman Bazalgette.*) My learned friend, Mr. Webster, was asking you about the occasion when the sewers rose, so that building operations

*Sir J. W. Bazalgette.*

22 May 1883.

at Paddington had to be stopped. At Question 12,722, you were asked, "Do you remember the "quantity of rain that fell?" and you replied, "Yes, "it was something very heavy. (*Q.*) Have you a "record of it? (*A.*) Yes, I have, but not here. "(*Q.*) Would you mind bringing us that here upon "the next occasion? (*A.*) You are referring, I pre- "sume, to Mr. Whitehead's premises"?—I have no record, except the record which I have put in, which is the register at Kew.

Examined by the COMMISSION.

12,941. (*Chairman.*) I wish to ask you some time or other, if you do not think it an unkind question. Is the river in a satisfactory state between Erith and Greenwich?—I think it is.

12,942. You do?—I do.

12,943. And there is no fair ground of complaint?—I think the statements which have been made have been very much exaggerated. Having regard to the position of the river and the locality, there is nothing to complain of.

12,944. When you say the "position of the river and the locality," I do not understand you; do you mean considering it has the misfortune to be so near a great town like this?—I mean that the site of the outfall is in a neighbourhood where there is no population, where there are chemical works, and which, according to my view, is a suitable place for an outfall to be; no harm really is occasioned by the discharge of sewage there.

12,945. I do not think that is quite an answer to my question; your answer seems rather this, that it does not matter that the river is not in a very satisfactory condition. But I would rather ask, Is it in a satisfactory state?—Of course, at the outfalls, you will find sewage, but I think very quickly it gets diluted and destroyed by the water of the river, and that by the time you get a mile or two from it you cease to find it.

12,946. And you say that it is no serious inconvenience either to the health or comfort or the enjoyment of the people who live upon it, or upon its banks?—I think not. I have heard it said that people were poisoned who were drowned by the accident to the "Princess Alice" just above the outfall. I have seen the water taken out of the Thames at that spot in a glass, and I have seen a gentleman in this room drink it, and there was nothing offensive in it.

12,947. (*Sir John Coode.*) But do you recollect that this was the hottest period of the year, and in a dry season when this happened?—It was in the early part of September. Then we have heard about the mud banks being so bad; now there are honourable members of the Commission who have been down with me to Crossness, and landed upon the shore, and walked upon the shore where it was as clean as this floor.

12,948. (*Mr. Abernethy.*) That was a very limited section of the shore?—It was all round the outfall. I have sat here and listened with astonishment to the statements which have been made by gentlemen living down the river. I have been down the river and have never been able to discover anything offensive until you get close to the outfalls.

12,949. (*Chairman.*) How near would you call close?—I think it was the observation of the Commission that when they got three-quarters of a mile below the outfall the unpleasantness had ceased.

12,950. And it was better above?—Yes, better above. I can only say that if you will give me the 4,000,000*l.* that would be expended upon this suggested work to expend upon other works in London I could lay it out much more for the benefit of London.

12,951. Do you estimate it would take 4,000,000*l.* to carry the outfalls further down?—Yes; that is the estimate I gave you, taking the working and expenses of pumping capitalised, and I say that money could be expended very much more for the benefit of London than by doing what has been suggested.

12,952. The sewage could not be utilised upon the Maplin Sands, or anything of that sort?—I should have been glad to have seen that scheme tried, but unfortunately it became a failure.

12,953. (*Sir John Goode.*) When you say the money could be better utilised, do you mean better utilised in the way of treating or disposing of the sewage, or in some other direction?—His Lordship was referring to a scheme which proposed to utilise the sewage upon the Maplin Sands.

12,954. But you said, before his Lordship put that question, that if the 4,000,000*l.* which would be necessary to change the position of the outfalls had to be expended, it could be utilised in some better way than by changing the position; did you mean by utilising the sewage or giving improved water supply or what?—I meant that there are other works upon which that money could be laid out. I say that if that money were expended, first in relieving London from floods; next in the that works we propose to lay out money upon, and lastly, in making communications across the Thames below London Bridge, that money would be expended very much more to the advantage of those living in London than it would be expended by the extension of these works to a more distant point of the river.

(*Mr. Bidder.*) Would your Lordship ask Sir Joseph this question. Assuming that the outfall was moved further down the river to some other place nearer the sea, whether there would or would not be the same amount of local effect or nuisance, if you please to call it so, at the new outfall as there is at the present one.

12,995. (*Chairman.*) I will ask Sir Joseph, but we know his answer beforehand, I think, because he would probably say there would be more water for the sewage to fall into?—It would fall, moreover, into salter water, and the more salt the water the greater the liability to create nuisance.

12,956. I suppose there are places upon both shores upon which there is scarcely any population at all, are there not?—Not upon the Thames.

12,957. But if you take the inlets—take the Maplin Sands themselves?—That is out of the Thames; it is right upon the Essex coast.

12,957*a*. (*Chairman.*) But how far would the 4,000,000*l.* take you?—I was contemplating going below Gravesend then. I was thinking of going to Higham Marsh and Tilbury; my estimate was 2,000,000*l.* for sewers, 300,000*l.* for reservoirs, say half a million for engines and building, and 50,000*l.* a year as the annual cost of pumping capitalized, making another 1,000,000*l.*, that is 3,500,000*l.* in round numbers.

12,958. (*Mr. Abernethy.*) Was not there an Act of Parliament obtained to carry the sewage down to the Maplin Sands?—There was, and the works were commenced; the Maplin Sands scheme did not propose to take the whole of the sewage of London away; they proposed, I think, one outfall sewer with a pumping station, the sewer to be 10 feet in diameter.

12,959. (*Sir John Coode.*) Did they propose to take all upon the north side?—No, they proposed to take as much as suited them, to use their reservoir, and to let the surplus go into the river.

(*Mr. Lumley Smith.*) Would your Lordship allow me to say that with regard to this, which is new matter, we rather understood the wish of the Commission to be that we should deal with the state of the Thames as it is.

(*Chairman.*) Yes, that is quite so, but the one or two questions which have been asked are not of any very great consequence; indeed Sir Joseph volunteered the observation about the 4,000,000*l.* himself.

The witness withdrew.

[Mr. George Chatterton called; examined by Mr. Bidder.

12,960. You are a civil engineer and an Associate Member of the Institution of Civil Engineers?—I am.

12,961. You have been professionally engaged for some years past in observations, taking soundings and sections on the River Thames, have you not?—I have been engaged on the Thames since May 1877 very frequently.

12,962. And particularly, may I take it, in the neighbourhood of the metropolitan outfalls?—I have been engaged more particularly in the neighbourhood of the metropolitan outfalls.

12,963. You say since May 1877, at that time I think you were employed in taking sections in Long Reach?—I was employed in the early part of May taking soundings in the river at Long Reach at a little below Purfleet, opposite the West Kent outfall.

12,964. (*Chairman.*) Employed by whom?—By the West Kent Main Sewerage Board. I was then their assistant resident engineer.

12,965. (*Mr. Bidder.*) That was with regard to the scheme that was then pending, and afterwards sanctioned by Parliament, was it not?—No, we were then carrying out the scheme.

12,966. Quite independent of the metropolitan sewage?—Yes, it is quite independent of the metropolitan system, they have an outfall of their own.

12,967. Where is their outfall?—Their outfall is near a place called Little Powder Creek in Long Reach.

12,968. A little below Dartford Creek?—A mile below where Dartford Creek discharges into the Thames.

12,969. At that time for this purpose you were taking soundings, as I understand, in Long Reach; would that be at all times of the tide?—No; you can only sound in the river during the last three hours of the ebb; immediately the flood tide commences you must give up, but in that way I had a very good opportunity of judging of the condition of the river when the sewage from the metropolitan outfalls would be passing down; it would about reach that part of the river in three hours.

12,970. Speaking of that time, May 1877, was there in the part of the river that you were engaged in in Long Reach a perceptible smell or indication of the sewage from the outfalls?—There was no smell, no perceptible smell of any kind, but there was an indication of the sewage. By watching the river very closely upon a very calm day, you could notice corks and bits of vegetable, and traces of grease, which would float upon the surface, but there was no possible means of detecting any large bulk of sewage as far as the nose or the eye could detect it.

12,971. Had you occasion to walk upon the foreshore frequently?—I had to take foreshore sections between high and low water, and that I did with long boots on, and, of course, I became practically acquainted with the mud in that business, and I never found the mud differed from ordinary Thames mud or more disgusting in smell, or in any other way than any other mud.

12,972. (*Chairman.*) That was about seven miles below the Crossness outfall?—Over seven miles below Barking.

12,973. (*Mr. Bidder.*) And six miles below Crossness?—Over six miles below Crossness.

12,974. You have been there since, recently, have you not, in the same part of the river?—Yes, I have been there every year since, and I was there a great deal last year.

12,975. Do you observe any change in the character and condition of the river or of the foreshore, comparing 1882, or your most recent visits, with 1877?—I do not think it is possible, as far as the eye or the nose is concerned, to detect any change in the mud upon the foreshore. I do not think it is altered in the slightest; there is certainly a decided alteration in Long Reach in the set of the tide. The set of the tide has altered in Long Reach in the last few years; it does not take a very skilled person to detect that. For nearly two years there has been an enormous amount of dredging taking place in Long Reach upon the north side of the river, which has deepened the river very much there, and cut a regular gut-way, you may say; and there can be no doubt that the set of the tide is a great deal more now upon the north side of Long Reach than it formerly was, but I do not think there is any accumulation of mud taking place upon the south side, and certainly the character of the mud I do not think is altered.

*Mr. G. Chatterton.*

22 May 1883.

12,976. Are you now speaking of Long Reach?—I am speaking of Long Reach.

12,977. At that time, in the months of June and July 1877, I think you were engaged almost daily in superintending the construction of the works of the West Kent Drainage system?—Yes, I was; the tanks of the West Kent system are immediately adjoining the sea wall at Long Reach, and it was my duty to be there to see that the work was being done, and I was down there all through that summer almost every day.

12,978. Those being summer months, June and July, did you observe any smell or suffer any inconvenience from any smell of the water then?—I never heard of any complaint. I never noticed any offensiveness, and I do not think it was possible for anybody upon the banks, by eye or by nose, to tell whether there was sewage being discharged at the Metropolitan Board of Works outfalls or not. We had 200 or 300 men employed at the works there at one time. I never heard a complaint from them, and they used to bathe in the river in hot weather.

12,979. Have you referred to the records of the temperature to see whether the temperature which Mr. Baldwin Latham suggested, viz., 65 degrees, I think it was, at which the river would begin to smell, was exceeded during that period?—Mr. Baldwin Latham put in a table of temperature which is taken from the Astronomer Royal's Returns and Greenwich Reports, and they are quite correct. I have gone through them myself. I do not agree with Mr. Baldwin Latham when he says that the river would become noxious at about a temperature of 65°. At Question 7414 he says: "The river would become noxious, "say, at from 65 to 70 degrees." I do not think that can be right. I think it must be something a good deal nearer 70 than 65, because, according to the tables that he put in, the temperature of 65 was reached upon 19 days in June 1877, and 25 days in July, and 30 days in August. I must say that during that June, July, and August I never heard of a complaint.

12,980. Nor noticed it?—Nor noticed it.

12,981. I do not want to go into too great detail through every month, but I think you continued for the purpose of the work you were engaged upon visiting the river all that autumn?—Yes. I may say that one part of the month of June (it is not given in Mr. Baldwin Latham's tables, but it is upon the records), I find that upon the 21st and the 23rd of June the temperature of the Thames exceeded 69°.

12,982. May I take it that the same absence of smell and perception of the sewage would apply to the autumn as to the months that you have already of?—It would.

12,983. Now in 1878 were you engaged in another investigation which took you to the banks of the river, examining them from Greenwich downwards?—Yes, I examined them with the view to see how much of the banks was being washed away; I examined the banks of the river and the saltings all the way down, more particularly upon the south side. I walked down all the banks of the river from Greenwich as far as Cliffe.

12,984. You inspected practically the banks of the river?—Yes, I went from Greenwich to Cliffe and Cliffe to Yantlet.

12,985. Now I will ask you this. To the best of

*Mr. G. Chatterton.*

22 May 1883.

your observation, would the mud which has been spoken of by witnesses from Erith, and which has accumulated at Erith Bight, differ from, or would it be similar to, the mud that has accumulated above and below?—I do not think as far as an ordinary person can detect it that there is any difference between the mud in Erith Bight and the mud at the mouth of all the creeks down the river. At Cliffe Creek there is a good deal of mud, and I do not think that any ordinary person can detect any difference between the mud there and the mud at Erith; I know I could not.

12,986. I think some witnesses spoke of the difference of colour between the mud above and the mud below; do you find that it is light above and dark below?—Yes, the general character of the mud is that it is of a light colour upon the top, and when you put your foot or rod into it it is black; it is black as far as I have examined it below Higham upon the north side.

12,987. Through that year, 1878, were you frequently upon the river?—I was.

12,988. Can you say whether your experience as to the condition of the river was the same or different from what you described in 1877?—I never found the river offensive. I never smelt the river of sewage except as anyone would, immediately up under the outfalls. I may say that I have a good sense of smell—I can smell as well as most people.

12,989. That we may know your opportunities of observation, how many times were you engaged upon the river during the year 1878?—I was 37 days engaged upon the river during the year 1878.

12,990. There is one matter I should have asked you about, I think—it was in that year that you collected the sample that was given to Mr. Keates, the late Analyst to the Board, of the fluid coming from the Beckton outfall?—I did; that was the year that the "Princess Alice" disaster occurred, and there were great complaints after that, as you have heard, and thereupon Sir Joseph Bazalgette advised the Metropolitan Board of Works to go down and see for themselves what was the condition of the river; they went down in a steamer upon the 23rd of November, and the press went with them, and Sir James Hogg invited a good many people; they went a good way down, I think as far as Gravesend, and in coming back they stopped the steamer opposite where the Princess Alice went down. I know that outfall at Beckton was discharging a very disgusting sort of tar refuse, and I went ashore and brought away a sample of it, and it rather astonished everybody there.

12,991. Was that sample afterwards analysed?—It was, but the appearance of it was quite enough to satisfy anybody. It was disgusting, it had a strong tar smell, and from its appearance it would be likely to be a deadly poison, I should think.

12,992. There was something said about a very offensive smell upon the water at the time of the "Princess Alice" accident, but I do not know whether it is within your knowledge that there was a very severe fire at some works upon the river?—There was a very severe fire, I heard, occurred that day upon the river at Messrs. Price's, I believe, but I do not know it of my own knowledge.

12,993. In 1879 were you frequently engaged upon the river?—I was engaged taking soundings a good deal that year.

12,994. Will you say at what place?—I was engaged at Long Reach taking soundings over the same lines as I took them in 1877, the temperature of the water at the time I took the soundings was 62, it was rather cold, the condition of the river was very good; that was in the month of May, and in June and July I took soundings of the river. Upon the 18th July the temperature of the water was 67·8. I have never noticed any smell in that part of the river from the sewage when I have been there.

12,995. Last summer, in 1882, you were frequently, almost daily, upon the river, were you not, collecting samples and making observotions in connexion with the proceedings before the Commission?—Last year I was altogether 59 days upon the river.

12,996. Have you gone to the outfalls and followed the sewage from the outfalls at the point of discharge, tracing it down?—I have. I have tried to estimate the nuisance, or so-called nuisance, upon the river myself, as far as it is practicable for any person who is not a chemist to do so. I have taken every means of observing the discharge of the sewage, and seeing how far it can be traced, the opportunity I was looking for was a bright, calm day; upon a rough day it is no use, you cannot see it, but I did follow the sewage down very carefully upon a fine day.

12,997. What day was that?—That was upon the 22nd May last year.

12,998. I assume you begun at the outfall. Going to the point of discharge, what do you observe at that place?—Upon the 22nd May I got to Barking about half past four, and the sewage was not being discharged at the time, but I was in an open boat and I went out immediately in front of the apron of the outfall, so that I would be in the middle of the sewage when it was discharged. When the sewage comes out first it is most dreadful, most sickening, and when you are in the middle of it you wish to get out of it as fast as you can, it is very strong—it is a smell that you never forget when you are in the middle of the black filth coming out of the outfall, but when I got in there I waited until there was a lot of sewage all round the boat, it was very black and very offensive, and I put in a float as I wanted to trace any particular portion of the sewage to see how far I could follow it, and I followed it down and took notes all the way down.

12,999. I think you started upon that journey according to my proof at quarter past five in the afternoon?—I did. I put in a float at quarter past five, immediately off the outfall and in the middle of the sewage. At quarter to six that float was abreast of the lower portion of the reservoir, moving slowly, and I took test tubes with me about a few inches long. I would fill them about half full of the sewage, or the river water whichever it was, and shake it up, and smell it to see if I could perceive any smell.

13,000. Did it smell?—Yes, when that was done near the reservoir it smelt strongly.

13,001. When did you next observe it?—I observed it next at six o'clock.

13,002. Where were you?—The boat was then off the centre of Lawes' Chemical Manure Works.

13,003. Could you see sewage upon the surface of the water then?—Yes.

13,004. What distance would Lawes' Works be from the discharging point?—It is a very short distance.

13,005.—Would it be half a mile?—It would not be half a mile.

13,006. Then I gather this was just after high water and the tide had not begun to ebb rapidly?—No, it was just the beginning of the discharge, the first of the ebb, on that three quarters of a mile below Barking outfall the float was a little to the north of mid-channel.

13,007. Could you see the sewage there?—Yes, you could detect particles of grease and bits of vegetable, you could tell there had been something discharged into the river and you could see traces of sewage, three quarters of a mile below, but mostly in the shape of floating particles.

13,008. At that point was there a smell in the air without shaking up the water?—No, there was no smell at all in the air from the water, unless it were taken up in the test tube and shaken violently, and then it did smell of sewage.

13,009. When did you next examine it?

13,010. (*Chairman.*) How came you to do this?—For the purpose of this Commission I was asked to do it. Then at one mile from Barking outfall a sample of water taken up and shaken violently smelt faintly of sewage. At a mile and a quarter the float was to the south of mid-channel, and the water smelt faintly when shaken.

13,011. (*Mr. Bidder.*) But was there any smell in the air then?—No. Then off Half Way House more than one and a half miles below Barking, the float I put in as a guide was about 100 yards from the south shore—the sewage had gone from the north shore to the south shore, and you could detect traces of sewage—the water was perfectly calm, as smooth as glass. Then before Crossness was reached, I could not detect the Barking sewage.

13,012. Neither by sight nor smell?—I could not detect it by the smell, but I could detect it by particles of vegetable, which I had known had come down, such as bits of cabbage, and potato skin, and such particles as were alongside my float all the time, having floated down, but as far as any solid particles of sewage or any discoloration generally were concerned, it was impossible to detect them, and the water, when taken up in the test tube, did not smell.

13,013. Not when shaken?—No.

13,014. Then following the ebb, you came to Crossness?—Yes, following the ebb I came to Crossness; a little below the Crossness outfall the float was 200 yards from the Crossness Quay Wall.

13,015. Did you then come into the Crossness sewage?—I was then in the Crossness sewage. Off the Belvedere Guano Works, which are between Crossness and Jenningtree Point, I was in the centre of the Crossness sewage; the water was as smooth as glass, and the wind was south, and light.

13,016. What was the condition of the river then; was there any smell?—The water when taken up in the test tube smelt when shaken, but there was no smell in the air until I got a little lower down, when there was a most abominable smell from Johnson's Fish Manure Works.

13,017. I was going to ask you this; in that part of the river you observed, did you not, some very offensive smells from a succession of factories upon the banks of the river?—Yes, but upon this day I think Johnson, as he generally does, eclipsed them all; he was very overopwering.

13,018. Now going on downwards, the next point I see is Wilson's Works?—Wilson's Works are opposite, upon the other side.

13,019. What was the condition of the water and the smell there?—You could still detect sewage from particles of vegetable floating, and little bits of grease, and that sort of thing—and in the water when shaken up you could detect a faint smell of sewage, but nothing that would cause any discomfort I should say.

13,020. Then next I think you come to Rainham Creek, or a point a little below Rainham Creek?—Yes, at a quarter of a mile below Rainham Creek, or 4 miles from Barking, the traces of sewage were visible, it was setting over towards the north shore.

13,021. Then 4 miles below Barking would be about 2½ miles below Crossness?—I call it 2 miles below Crossness.

13,022. Was there any smell there?—No.

13,023. Then you came to Coldharbour Point, what did you observe there?—Off Coldharbour Point the float I had in was about 200 yards from the north shore.

13,024. Were there any traces of sewage there?—Yes, you could detect it there of course. When I say "traces of sewage," they were acting the same part as my float was, they were bits of vegetable and small fragments of insoluble substances floating down.

13,025. Was there any smell there?—No.

13,026. Did the water smell when shaken?—No.

13,027. Then when you got to Long Reach, what did you observe?—At the upper end of Long Reach, 6¼ miles from Barking, I could detect a few traces of sewage; it was a beautiful evening.

13,028. To shorten what I have to say, I will ask you, where did you finally lose the sewage?—I finally lost all trace of it opposite Long Reach Tavern, or the "Royal Hotel," Purfleet.

13,029. (*Sir John Coode.*) Which end of the Reach is that?—That is the upper end, seven miles from Barking. It was, as I say, a beautiful evening, and in the boat I cast across, and across the river, and it was impossible to detect any trace of floating matter from the sewers.

13,030. Was all this upon the 22nd May last year?—Yes.

13,031. (*Mr. Bidder.*) If I followed you rightly you had long since lost it as far as smell was concerned, before you came to Erith?—Yes, the last time I smelt it was somewhere below Jenningtree Point.

13,032. Those traces of sewage that you were enabled to recognise down to the point you have mentioned, were the particular particles accompanying the float?—Yes.

13,033. (*Chairman.*) Where is it the witnesses say it became necessary to take the fish out of the wells?—In the summer time they say they have to take them out at Gravesend.

13,034. So that taking the fish as witnesses, they are conscious of the sewage much lower than you are?—I would not say that; I would say they are conscious of the effect of the sewage, but not of the sewage itself. I think the fish have rather a finer taste than you would imagine—the fish are in the summer time, I think, taken out Gravesend, but in the winter they are not.

13,035. They come higher in the winter time?—As far as that goes, they can come right through the outfall—the Dutch eel boats I have watched coming through the outfalls.

(*Mr. Beaumont Morice.*) One of my witnesses said that at low water fish will not live at Gravesend.

13,036. (*Mr. Bidder to the witness.*) The day you describe so fully, I gather from its calmness, was an exceptionally favourable day for tracing the sewage a long way?—I was out upon the river almost every day last year, and I never saw any day so favourable for noticing the discharge. If there is any wind at all you cannot notice it—the thing is broken up.

13,037. (*Sir John Coode.*) Have you any evidence with regard to the quanty of fresh water coming over Teddington Weir for a week or two before this month of May?—I have Mr. John Taylor's gaugings at Seething Wells.

13,038. (*Chairman.*) Speaking generally, had there been much or little rain?—I cannot remember at the present moment, but the Greenwich rainfall is given in Whitaker's Almanack, day by day for the last year. I find that upon the 22nd of May 1882, there was ·02 inches of rain fell at Greenwich, and there had been no rain since the 6th of May, therefore, there had been no rain from the 6th until the day I was there—it was rather a dry period, as there were 16 days without any rain at Greenwich. There was some rain upon the 6th, and the 4th, and the 3rd, but there might, of course, have been rain up above though there was none at Greenwich.

13,039. (*Mr. Bidder.*) Now later on, in the summer of last year, I see you were on the river upon a great number of occasions?—I was.

13,040. And you took a large number of samples, which have been analysed by chemists?—I did. I may as well put in for the Commission a plan, showing the position of those samples, as I daresay they will be referred to hereafter. This plan shows the position of the samples, and this is a cross-section of the river showing the exact spot, and state of the tide at which each sample was taken.

*The plan and section were handed in.*
*See Appendices A.K. 1 and 2.*

13,041. I see that several times in the month of June you were there?—I was.

13,042. And several times in July, the dates of which you can give?—I was.

13,043. And I will ask you this: upon those occasions did you find, excepting as you have already described, when you got into the sewage flow immediately near the outfall, that you could perceive any smell from the water of the river?—I do not think there was any smell in the Thames last year, unless

*Mr. G. Chatterton.*

22 May 1883.

you went out into the immediate neighbourhood of the outfalls, when you were not really in the Thames at all, but were in the sewage; but for a reasonable distance below Barking and Crossness, say midway between the land magazines in Barking Reach and and off Jenningtree Point in Halfway Reach, I do not think there was anything to complain of at all; there was certainly no smell from the water any day last year that I was out.

13,044. (*Sir John Coode.*) When you say there was no smell from sewage, was there no smell of any kind or description?—There were very bad smells from the factories, but when once the sewage was dispersed into the bulk of the river water, there was no smell from the Thames itself.

13,045. Do you think that you are safe in assuming that the smell that was there, was the smell from the factories, and that there was no sewage smell mixed up with it?—There was no sewage smell. I have done everything I could to detect the smell of the Thames water. I have got out of my steamer on different occasions and steamed up past the outfalls as fast as she could go, and I have got into a small boat astern, and lain down on my face and put my nose within an inch of the water. I did that on one occasion when the water was over 65 degrees. I think it was 66 degrees, and when I came into the neighbourhood of Crossness, within a very short distance of Crossness, I could tell where I was by the smell of it.

13,046. About how far?—About 250 yards off.

13,047. You could see nothing in the way of sewage until you reached that point?—I could see perhaps bits of cork, and so on, upon the surface. I knew that the sewage was being discharged; but when you pass out of the outfall again you lose the smell; it is a very easy smell to detect, and there is no way to detect it so well that I know of as in going astern of a screw in a boat; it is a very favourite way of the watermen going about on the Thames, and I have no doubt they get the benefit of it if ever it does smell when they do so.

13,048. (*Mr. Bidder.*) If the Commission were to go down in a steamer, you believe that unless it were some particularly and exceptionally hot day, they could perceive no more than what you describe?—No; what I have described is nothing exceptional; everybody admitted last year that there was no smell; the fishermen are the people who complain the most, and they admitted that there was really no smell from the water last year.

13,049. You spoke of a sample you took at the Beckton Outfall upon the occasion of the "Princess Alice" catastrophe, have you observed that the Beckton Outfall does discharge offensive matter in recent years?—I have. I noticed it discharging upon the 13th June last. I do not place much importance upon the discharge of the Beckton Outfall, except that Mr. Baldwin Latham brought out a table showing that the thing discharged very seldom, and that what it did discharge was not very noxious.

13,050. I will also ask you whether you observed anything which was noxious at that part of the river known as Bow Creek?—Yes, I was going down the river upon the 3rd of July, and I got opposite Bow Creek about 9 in the morning, and I noticed a very large quantity of sewage coming down Bow Creek at low water, and the creek itself was in a very muddy condition, the Beckton outfall was also discharging that day.

13,051. (*Chairman.*) That is upon the River Lea, is it not?—That is the River Lea, and the sewage that I noticed was the West Ham sewage.

13,052. (*Mr. Bidder.*) Have you noticed any matter discharging upon the surface of the river from any of the factories of an offensive charactor?—No, I have never been able to see any great discharge from the factories. I have seen some refuse coming out of them. I know it does come from some of the factories, but I have never been able to discover it except on one occasion, at Rainham Creek. I have noticed a good deal of refuse being pumped into the river from barges.

13,053. Do you say "pumped into the river"?—Yes.

13,054. Of what character?—It is some refuse from gasworks. I do not know exactly what it is called, but I have seen a barge go down opposite Blackfriars Bridge in the summer-time of last year. It was upon the 3rd of July, and they were pumping this stuff away into the river as hard as ever they could, and there is a lot of bilge water from the paraffin ships which is pumped into the river, that is to say leakage from the casks.

13,055. (*Sir John Coode.*) Where do you say this barge came from, that was discharging opposite Blackfriars Bridge?—It came from these gasworks, which are just above Vauxhall Bridge.

13,056. (*Mr. Bidder.*) There is another day now later on. You completed your observations on the 27th of July; I will not ask you to go through them in the same detail, but upon that day how far could you trace or detect, by smell or otherwise, the sewage from the outfalls?—I could not distinguish the Barking sewage that day much further than between the land magazines.

13,057. What distance is that?—It is exactly 1,000 yards.

13,058. Did you notice in July, because we have heard a good deal of evidence of people smelling bad smells in the neighbourhood of the river, whether the smell of the various factories was particularly bad at that time?—Yes, on some days it was very bad, in fact every day that the wind was favourable. I refer more especially to the factories below Crossness. The smell from Johnson's factory was something d. eadful; the smell from Lawes' works is occasionally very bad, but the smell from Johnson's and the fish manure factory upon the opposite side was overpowering.

13,059. Now with reference to your evidence as regards the fish, you said something about that just now, but my learned friend, Mr. Beaumont Morice, was contending that there was evidence that no fish could live at Gravesend in the summer; have you observed fish in that part of the river?—I have frequently seen them catching fish at high water opposite the Ship and Lobster, and I frequently noticed fish last year in the wells of the vessels at Gravesend at low water, and they never take them out all through the low water; they are towed up by a tug upon the flood. Upon the 7th of August last year, I went on board a Dutch eel boat called the "London Van Work." I came up with her from Long Reach right through the outfalls, and I went below and watched the fish as we were coming up through the outfalls, and they did not seem at all uncomfortable; the captain told me it was the usual thing; it was his usual cargo; he had about 15 cwts. of eels on board.

13,060. Then on the 15th of August you went to examine the river above bridge at Battersea, did you not?—I did.

13,061. Did you make an examination to see if there were important contributions to the sewage of the river below Teddington?—Yes, there is certainly a great deal of sewage discharged into the river above London Bridge; I noticed upon that day at the Chiswick outfall, where they are supposed to purify the sewage, that they were certainly neglecting it upon this occasion.

13,062. Was that discharging sewage into the river?—Yes, and very strong sewage too; our chemists were on board that day, and they took a sample of it.

13,063. Then in the month of August, and again in September, through the Autumn, did you carry on further observations in the river?—I was engaged during the whole of the latter portion of August in taking soundings at Erith for the purpose of this inquiry,—from a little below Jenningtree Point to below Easton and Anderson's works.

13,064. Shortly, may I take it that the same description substantially will apply to your observations

upon these occasions, as regards the perception of the sewage in the neighbourhood of the outfalls, and its non-perception further off?—As far as the eye and the nose are concerned, you cannot detect the sewage unless it is a calm day. You will see, even as far as Erith, traces of vegetable and other floating matter which are not offensive, but they must have come from the sewers; they simply act as floats; they are insoluble; but as far as any smell from the Thames goes, there was no smell from the Thames in Erith Bight last year.

13,065. Did you, whilst taking soundings, take means to bring up mud from the bottom in any places?—I did.

13,066. What was the result of your observations of the mud. You are aware that it has been described to us as filth rather than mud. You saw many samples of mud in these soundings, but you saw, I think, none corresponding to this description?—No. In some parts, as in Erith Bight, there is a great deal of mud, but it is mud which I should describe as being mixed with a great deal of water; it is a very soft mud, indeed.

*Mr. G. Chatterton.*

22 May 1883.

13,067. (*Sir John Coode.*) Is it slimy or clayey?—You can hardly call it slimy.

13,068. You would call it sloppy?—It is not offensive, but I should not care to work in it very much or in any mud.

13,069. Then this mud at Erith is really offensive; I gather that from your last remark?—I should not care to work in any mud; not as some of the witnesess have described, working up to their middles in it.

13,070. (*Chairman.*) There is some mud which has a sort of sedgy smell?—I do not think there is any difference between the Erith mud and the mud right away down the river or the mud right up the river. It is certainly lighter in colour at Erith than mud in the River Mole.

Adjourned to to-morrow at half-past 12 o'clock.

# THIRTY-FOURTH DAY.

## Wednesday, 23rd May 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.

FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, Esq., F.R.S., *Secretary.*

Mr. GEORGE CHATTERTON further examined.

13,071. (*Mr. Michael.*) You have some figures, I believe, to put in?—I was asked for some tables yesterday of the discharge over Teddington Weir, and I now put in some gaugings taken at Seething Wells, at the Lambeth waterworks, by Mr. John Taylor, the engineer to the Lambeth Water Company; the table also gives the height of the Thames at this place above summer level for each day. I find that there was not very much water coming down at the time. Upon the 20th of May 1882 there was 577,000,000 gallons; on the 21st there was 601,000,000 gallons, and on the 22nd there was 653,000,000 gallons; the mean daily flow here is about 833,000,000 gallons.

13,072. What is the highest?—The highest for the month of May is 1,697,000,000 gallons in the twenty-four hours.

(*The Table was handed in. See Appendix A L.*)

13,073. (*Chairman.*) This table relates to the days when you examined the river?—Yes.

13,074. I suppose the object of it is to show that there was not an unusual quantity of fresh water in the river?—Yes.

13,075. Does it show that?—It shows that there was rather a small quantity of water coming down.

13,076. I suppose you give a general answer, in the negative, that there was not an abnormal quantity of water in the river, and justified that answer by the tables?—I do.

(*Mr. Michael.*) The quantity which came over upon that day when you made your special observations, and the days immediately before, was very much less than the mean of the quantity which passes over. It was important, as Sir John Coode put it to the witness, to know the quantity which passed at that time. The mean was very much larger than on the days you have given, there was about 22 per cent. less on these days than the mean.

*Mr. G. Chatterton.*

23 May 1883.

13,077. (*Chairman to the witness.*) Those are not your own gaugings, of course?—No, I am not responsible for these gaugings in any way. I got them from Mr. John Taylor.

13,078. (*Mr. Michael.*) You were beginning yesterday to give some observations you had made with respect to the set of the tide?—I have observed the set of the tide from the outfalls down the river. I thought I might perhaps just state where my observations were.

13,079. Did you put in a float at Barking in order to see what the set of the tide was?—I have made a good number of observations. Generally, if you put in a float opposite Barking outfall at high water, it will move at first very slowly until opposite Barking Creek. It will then begin to be deflected towards mid-channel; on reaching the land magazines or 1,000 yards below the Barking outfall, it will be about mid-channel; it will then set over close to Leather Bottle point, and, having turned the point, it will move parallel to the Crossness quay wall, or river wall, until nearly opposite the Belvidere guano works, when it will set over to the Essex shore, in the direction of Coldharbour Point; it will then pass close to Coldharbour Point, which is a point upon the Essex shore immediately opposite Erith, and it will set from Coldharbour Point towards the "Castalia," the twin Channel ship which lies there.

13,080. (*Sir John Coode.*) But she may be moved; geographically, where is that?—It is in about the centre of Erith Rands. The float will then set down to about opposite Easton and Anderson's works.

13,081. (*Mr. Michael.*) If a float is put in at another part of the tide, does it take the same course?

*Mr. G. Chatterton.*

23 May 1883.

—No, a float put in at the Barking outfall from one hour and a half to two hours after high water will take the same course until it gets to Leather Bottle Point or Halfway House, but instead of taking the south shore, and parallel to the Crossness quay wall, it will go over to the north channel, to the deep water upon the north side, and pass close to Dagenham jetty, and so along the north side of Halfway Reach and Erith Reach, and follow the same course as I have described already.

13,082. From that you are able to tell how the sewage will affect Erith?—As far as Erith is concerned, Erith being in a bight, the sewage never passes straight into the bight; it always keeps the opposite side when discharged, either at Barking or Crossness.

13,083. That is equally applicable to the Barking sewage and to the Crossness sewage?—It is so; the sewage discharged at Crossness follows a parallel course to the river wall until it reaches Jenningtree Point; when it reaches Jenningtree Point, it is deflected to the Essex side, and goes along down that northern side, and passes close to Coldharbour Point, in the deep water. I have never seen a float go into Erith Bight at that time of the tide.

13,084. Have you made many observations?—Yes, I have.

13,085. (*Chairman.*) I should like to ask you this, the witnesses say there is a place where the hard has got very much covered?—Do you refer to Erith Causeway?

13,086. If I understand you, the sewage ought not to have got there?—No, the sewage cannot get there upon an ebb tide.

13,087. Have you any notion how the shoaling has been caused there?—Yes, I know it perfectly. Wherever you find slack water in the Thames for any lengthened period, you must have a deposit, because the suspended matter goes to the bottom. Now, of all parts of the river, that near Erith Causeway is in about the slackest. On an ebb tide, at three hours after high water, there is slack water there, and at three and a quarter hours, say, after high water, immediately above Erith Causeway, when you get opposite the Corinthian Yacht Club, which is above, near the church, there is a considerable eddy tide all the way up there; I should think an eddy tide at the rate of one and a half miles an hour.

13,088. (*Sir John Coode.*) Is the Corinthian Club above the causeway?—Yes, it is.

13,089. How far above? I suppose you have not the track of the currents laid down upon the chart?—Some of them I have, but Mr. Law, who is coming after me, will give you those details. I have made careful float observations there; and below Erith Pier, which is a little below Erith Causeway, there is never any tide up, so that Erith Causeway, where this accumulation of mud has taken place, lies between two currents, one going down, and the other going up—you can make those observations yourself any day there, and you will find that three hours after high water, upon an ebb tide, there is slack water there, and at no time of the tide is there any considerable current over Erith Causeway. At 120 or 200 yards out from the end of the causeway, there is a down current, the eddy tide does not set up there, but the eddy tide is very marked indeed, and very curious there.

13,090. There must be something very exceptional there, because it is very remarkable that you should have a bight like this, with slack water, and it is for that reason I should like to see the currents laid down; there must be some abnormal conditions there at work?—There are, from its enlarged sectional area.

13,091. (*Mr. Abernethy.*) How is it with regard to the flood?—Upon a flood tide there is no eddy, but there is a very slack tide as far in as Erith Causeway.

13,092. (*Chairman.*) Sir John Coode raises a doubt how this can well be; but it rather strikes me as not an unreasonable supposition, because, the river bending round in this way, the flow of the water is against the north side of the river always, is it not?—The set of the tide there is for Coldharbour Point.

13,093. It flows against the north side?—Yes.

13,094. Then, when it gets below Erith, it flows against the south side?—That is not the explanation that I have in my mind. I would suggest that there is an excess of sectional area there. If you were to integrate the whole cross section, and add the whole tide running in one direction, and subtract the eddy tide going in the other direction, you would get at the true mean velocity of the stream.

(*Sir John Coode.*) I suggest that it is very remarkable; with this bight, and the current running through it, there should be this slack water here.

(*Mr. Michael.*) I am very sorry that Mr. Law was unable at the moment to be called, we are now interpolating Mr. Chatterton's evidence out of its proper order.

(*Chairman.*) I do not know if one may be permitted to assert one's own experience in a matter of this sort; it was always safe to keep upon what you call the convex side if you were rowing against the tide, was it not?

(*Witness.*) I do not know that.

13,095. As a rule it is at all events, because, if you have a concavity, the water would be more upon that side than it would be upon the other side?—That is all very well upon the Upper Thames, but I do not know that it will be a useful rule in the tideway.

(*Mr. Michael.*) I will pass this by for the present.

13,096. (*Chairman.*) Were not these causes in existence a long while ago—long before the sewage?—No, there was always an eddy tide at that place, but, on account of the dredging operations which have taken place recently, that effect has been more fully produced of late years.

13,097. (*Mr. Michael.*) You will see what the sectional area is at the present time, and how it has been increased, giving the reason for any deposit which has taken place. (*To the witness.*) Now we will go to the Erith Outfalls. You have examined all the existing outfalls, have you not?—Yes, I have. I have examined the sewer outfalls at Erith.

13,098. Will you state what nuisances you have observed there from the outfalls?—For any person working in the immediate neighbourhood of one of those outfalls there would certainly be a local nuisance. This (*producing a plan, see Appendix A M.*) is a plan of Erith, and immediately below Erith Pier there is a 15-inch sewer discharging on the river. That place where you see marked "Erith Gardens" upon that Ordnance map is called the South Eastern Railway wharf; I think it is Mr. Beadel's.

13,099. Does that mud remain uncovered by the tide?—Yes.

13,100. For how long?—I should think the end of the pipe would be exposed, from when the tide left it until the tide came up again, for three hours.

13,101. Have you noticed sewage coming out of that pipe?—I have.

13,102. What is the character of it?—I call it the "essence of sewage."

13,103. Do you mean it is so strong?—Yes, it is strong, and as if it had come from very badly constructed sewers.

13,104. (*Sir John Coode.*) Is there any reason why that should be more concentrated than the metropolitan sewage?—Yes, there are no good sewers in Erith, and it is old stagnant sewage.

13,105. (*Chairman.*) Is there any other criterion of the nuisance than the number of people who send it out?—Yes, I think the age of it, my Lord, the number of days between the time when it left the closet and got into the outfall; fresh sewage is not anything like so objectionable. But, however, I shall not say anything more about that, because there was a sample of it taken by the chemists, and they will explain to you what it was.

13,106. Can you give us what the population which drains into that sewer is?—That I will give, and

there is also a report of Mr. Edward Easton's which is put in.

(*Mr. Michael.*) It has not been put in, and I do not know when your Lordship would like attention to be drawn to various documents which have been agreed upon on both sides to be brought before the Commission. There are many important statements that we have agreed as to various points, and much has been cut out so as to make them as short as possible.

(*Chairman.*) We shall have summings up and speeches, and I suppose it would be done then.

(*Mr. Michael.*) That would be a break of continuity, and it would be desirable to have an opportunity of calling your attention to the most important passages as soon as possible.

(*Witness.*) What I say with regard to the outfalls is that a man working in the mud, and in the immediate vicinity of that outfall, in hot weather, must find it unpleasant; the mud will be tainted with the sewage. And if Sir John Coode will look upon the plan next to Erith Pier, and immediately below it, he will see a coal wharf, which was called the Erith Gardens; they try to bring barges alongside of that place, to unload them, and, in order to do so, they have excavated or dredged a channel in the mud there, and in order to keep that channel clean, they must flush it. You will see a place there called The Pier Hotel; immediately in front of that there is a tank, and that tank is filled every high tide, and discharged at low water, by which means it flushes out the portion in front of Mr. Beadel's wharf.

13,107. (*Sir John Coode.*) What is the "flood gate" one sees upon the plan, has that anything to do with it?—No, I think that is some land drainage. Now, that tank that I have referred to is not sufficient to keep the channel clear, but I have noticed that there are a certain number of men there, two or three men at work excavating, and always trying to keep the thing clear.

131,08. (*Mr. Lumley Smith.*) It would be convenient to have about the size of this tank?—I think it is about from 15 to 20 feet long.

131,09. But that does not give us the dimensions?—I have not measured it, it may be 25 feet long; you will see it at work any day down there.

13,110. (*Mr. Michael.*) Is there by the causeway another outlet of sewage?—Yes, there are a lot of small pipes coming in there. I have surveyed all those pipes and marked them on the plan myself; the most important of them is at the flour mill just above the causeway. I think I have called it upon the plan "Sewer C."

13,111. Does that run over the mud?—Yes, it runs over the mud that remains in a most disgusting state. When I went to examine it, I found a great quantity of sewage which had been deposited there the tide before, the tide is so slack there that it will not carry it away. The mud all along that place is locally fouled by the Erith outfalls, of which there are a good number.

13,112. (*Sir John Coode.*) Are there any more than you have marked upon the plan?—I do not think there are.

13,113. (*Mr. Abernethy.*) Are the dimensions marked upon the plan?—Yes, the dimensions are marked.

13,114. (*Mr. Michael.*) Is there any local accumulation of mud at the causeway of the Corinthian Yacht Club; in the first place, how is the causeway constructed?—The Corinthian Yacht Club Causeway is constructed on piles, and allows the water free passage for ebb and flood through the piles.

13,115. Does the mud accumulate?—No; there is a general accumulation all along the bight, but there is no local accumulation, that is to say, there is no heaping up at the causeway; the mud is no higher at the causeway than it is 100 yards above or 100 yards below.

13,116. What is the character of the other causeway?—The other causeway is a solid groyne running out.

13,117. Does that follow the usual course of groynes, heaping up the mud to the top of the causeway?—It does heap up the mud to the top of the causeway on the ebb side; on the other side there is no mud heaped up. I have no doubt that the way that causeway is constructed adds to the accumulation of mud at that place.

13,118. I think you have prepared a plan, have you not, upon which you have marked upon both sides of the river the factories which give out noxious smells?—I have. (*See Appendix BN.*) The most noxious factories that I know of on the Thames with regard to smell are the ones between Erith and Woolwich, upon the north side of the river. I have noticed lower down, upon the Essex side, there are some fish manure works, and then above that there are Messrs. Miller and Johnson's manure works, Wilson's chemical manure works, and above Rainham Creek there are the gas purification and chemical works, and the Rock Portland Cement Company.

13,119. (*Sir John Coode.*) That is hardly a noxious trade, is it?—It is not a smelling trade; it is a smoky trade. Then there is a candle factory above that, and then there is Crossfield's manure works, and then then there is the Barking guano works; then there is Lawes' chemical manure works, and then there is the Beckton gasworks; there are a great number above. I do not know that I need mention them all.

13,120. (*Mr. Michael.*) You have a list of them, have you not?—I have.

13,121. There are between 30 and 40, are there not?—There are 31 altogether.

13,122. (*Sir John Coode.*) Does that list include any other cement works?—No, but sometimes I have noticed a very nasty smell from those works. I do not think it is a real cement works.

13,123. (*Chairman.*) Are there discharges from those works into the river, or merely foul smells from them?—There are vapours.

13,124. (*Sir John Coode.*) I suppose any discharge from those chemical works is prohibited by the Metropolitan Board of Works?—The Metropolitan Board of Works have nothing to do with it, but the Conservancy would prohibit it.

13,125. So that, as far as they are concerned, it is a question of noxious smells?—Yes; it is for that purpose we have given them in the list.

13,126. (*Colonel Ewart.*) You did not notice any noxious discharge, except at Beckton?—No, I have noticed some discharge from one or two of the factories, but then it is only from a pipe.

13,127. (*Sir John Coode.*) If the discharge from those other factories is prohibited by the Corporation, or by the Conservancy, how is it the Beckton discharge is not prohibited?—I suppose that Beckton would say they merely discharge sewage.

13,128. (*Colonel Ewart.*) It is a question of how far the prohibition is enforced?—I do not think there is any prohibition enforced, or anybody who enforces it, at all events.

(*Mr. Lumley Smith.*) You will find some evidence upon the notes that what came from Beckton was pure water, and that there was no sewage at all in it; it does not follow that, though a discharge is seen, it is a noxious one.

Cross-examined by Mr. Lumley Smith.

13,129. Now, with regard to what you told us yesterday, in 1877 you were down, as I understand, upon work connected with the West Kent sewage scheme?—I was.

13,130. Not for the purpose of examining the river at all, but in the course of your duty, you had to be down upon the river?—No, I had double duty to perform. When I was appointed upon the West Kent works, the first thing was that I was ordered by the West Kent board to prepare soundings of the river,

*Mr. G. Chatterton.*

23 May 1883.

and an accurate survey of the bed of the river, in front of their works, because they anticipated that, in the event of any shoaling or unpleasantness taking place, they would be held responsible for it, and I was instructed to make the survey, which I did.

13,131. But that was not with a view of testing the quality of the water at all, but for the purpose of seeing the nature of the bed of the river in front of the West Kent works?—I believe also that samples of water were taken for the purpose of the West Kent works.

13,132. Where were the soundings taken that you spoke of yesterday at the West Kent outfall?—About 300 yards above Little Powder Creek.

13,133. As I understand, the result of your observations taken then is summarised in the general character you have given us of the banks—you do not produce any sections or any documents which were made at that time?—I do not.

13,134. But I think what you told us was that, as far as the banks were concerned, you did not find them covered with mud?—No; there is always mud upon the foreshore in Long Reach. When I knew the foreshore in Long Reach first, upon the south side it was mud between high water and low water, except in particular places. What I said was that I did not notice any change in the character of the mud between those dates—in Long Reach, from high to low water, it has always been mud.

13,135. Then it is the fact that between high and low water in Long Reach you do find mud?—Yes, and it always has been so.

13,136. Your observation dates from May 1877, I think?—Yes.

13,137. You tell us that you have not noticed any change in the character of the mud; between what dates are you speaking when you speak of there being no change?—The same dates, 1877 to 1882.

13,138. You still find mud upon the foreshore, do you not, between high and low-water mark?—Yes.

13,139. It is a straight long channel, the name Long Reach rather points to that?—Yes, it is a straight long channel, but the bed is uneven.

13,140. Is there a considerable current down the bed?—Upon the north side there is.

13,141. Your observation is based upon what you saw upon the bank, I understand?—Yes, walking about the bank.

13,142. We have had some evidence about anchors which were taken from the bed of the Reach, and so on. You have had nothing come under your observation, have you, which would show the condition of the bed of the river?—I have.

13,143. What have you?—When I sounded I took the samples. Every time I take a sample the pole is pulled up afterwards, and I look at it to see what is on the bottom. The sounding pole is of wood, with an iron shoe upon the bottom of it. I got that hollowed out and grease put in it to pick up whatever was upon it. Upon the gravel you can hear it, and upon the shingle and the sand you can hear it, and you know it at once; but in the mud you take it up. The man who is sounding takes a look at it, and very likely smells it. I ask him if it smells, and he says whether it does or does not.

13,144. But what is the result of this?—There has been always mud in parts of Long Reach, but there has not been mud all along the bed of the river.

13,145. I cannot understand why you should have required to have it smelt in 1877. I can understand why you should have it smelt now?—I have always examined the river in that point of view to see what effect the sewage would have upon it. As we, the West Kent people, were discharging sewage into the Thames there, and I being placed in charge there, it was natural I should acquaint myself with the character of the river before the sewage was discharged into it, so as to be able to compare it with what it was after the sewage had been discharged into it.

13,146. You were providing yourself with knowledge and materials in case an inquiry arose as to what was the state of the river and of the mud before and after?—Yes, and for another reason.

13,147. But that is sufficient; have you kept no memoranda at all with regard to the character of the mud?—Not as to the smell, but it is to be characterised as a light mud and a dark mud.

13,148. The year 1877 was a wet year, was it not?—I do not remember.

13,149. I am told that one of the biggest floods that ever occurred in the Thames happened in 1877; are you able to tell me whether it was or was not a wet year?—I am not. I have not the tables with me.

13,150. Can you give me the times when you made your observations in 1877?—Yes, May 4th, May 8th, May 9th, May 10th and 11th, and the whole of June, I was upon the bank there, and a great deal upon the river; also the whole of July, and the whole of the rest of that year.

13,151. Where do you get your dates which you took; from your reports, or from memoranda made at the time?—They were taken from my level books principally.

13,152. I presume, from your not putting them before us, that there is nothing in them specially with regard to the character of the mud?—No. Then I should say that I refer to the tables of the temperature of the Thames upon those days. I did not take the temperature myself, but I look to the common source of information, the Greenwich records. I have them all copied out, for ever since they were taken, from the year 1844 to the year 1879, when they were given up, and if his Lordship cares about it, I will present that to the Commission.

13,153. That is copied from the record at Greenwich of the temperatures of the Thames?—Yes.

13,154. Taken where, at Greenwich?—Yes.

13,155. But you have no memoranda at all with regard to any smells of mud at that time?—No; there never was a smell.

13,156. But have you any memoranda made at the time?—No, I have not.

13,157. Where do you get those dates, May 4th, 8th, 9th, 10th, and 11th?—They are taken from my level and sounding books.

(*Chairman.*) It is remarkable that you should have thought it necessary in the interests of your employers that you should make an inquiry into the condition of the water, and should have made no notes or memoranda of your observations.

13,158. (*Mr. Lumley Smith.*) Do your sounding books show anything more than the depth of water and the existence of mud?—They show where the mud is.

13,159. Not the character of the mud?—No, not the character of the mud, but where the mud is as compared with gravel and sand; I must rely upon my memory for the character of the mud.

13,160. (*Sir John Coode.*) Are the level books forthcoming?—The level books are not here, but they can be produced; but there is nothing in them except a mass of figures which relates to a matter which is not now before the Commission.

13,161. (*Mr. Lumley Smith.*) After 1877 your occupation there ceased, did it not; what had you to do then?—I had nothing then to do with the West Kent Drainage after 1877. I was then in partnership with Mr. Henry Law.

13,162. When were you next taken down to the river?—I was engaged to survey the banks of the river in 1878.

13,163. Was that with a view to the Mud Inquiry?—It was with a view to a Report that was issued afterwards.

13,164. For the Board of Works?—For the Board of Works.

13,165. It was not in 1878 that you at all went upon what I may call your smelling excursion?—No, that was last year.

13,166. Have you any memoranda in 1878 with regard to the character either of the water or of the mud?—No, I have none: that was when the investigation

was made for the Mud Inquiry; there are ample records of the condition of the water during that period which will be put in by our chemists when they come.

13,167. As far as you personally are concerned, you give us no information with regard to your visits in 1878, except as to your going down in a steamer in February? — I walked down the river banks in February to Yantlet, and visited all the saltings.

13,168. But yesterday your evidence was confined to having gone down in steamer after the loss of the "Princess Alice"?—I was out upon the river 37 days in that year altogether, and the 23rd November was one of them.

13,169. How do you get the 37 days?—I have taken that from my level books. I have no regular diary. I was down the river 37 days as I make it, it may be more or it may be less, but I took it as 37 days from my level book; many of those times were unconnected with this inquiry.

13,170. Were you taking levels in 1878? — Yes, almost the whole year; I was engaged for the Metropolitan Board of Works in connexion with the purchase of the toll bridges.

13,171. I do not remember any bridge at Purfleet? —No; when I say 37 days, I mean on the river. I do not say 37 days at Purfleet.

13,172. But we are dealing now with below London; I do not see how any days that you spent above London Bridge, say at Putney or Hammersmith, can affect this question?—No, that is true.

13,173. But it appeared yesterday as though all the days you mentioned you had been on the lower river? —That was not what I intended to convey.

13,174. (*Prof. Williamson.*) When you speak of 37 days, does that mean that on 37 days you were there for some indefinite period, or does it mean 37 times 24 hours?—No, it would mean a day's work upon the river of 6 or 7 hours each; the greater part of these 37 days I was not below the outfalls at all, but up the river between Waterloo and Hammersmith Bridges, and up the river generally.

13,175. (*Mr. Lumley Smith.*) On how many days in 1878 were you down at the outfalls, or below them? —I do not remember, but I should say perhaps 10 out of the 37.

13,176. What business were you on down below?— I made some current observations of the set of the tide for the Mud Inquiry, which was heard. I was engaged making float observations.

13,177. The mud case came on a little later?—Yes, but still we were preparing for it, and there was a Report published in that year for which I did most of the out-door work.

13,178. Could you give me the date of the Report? —It is April 1878.

13,179. That is the Report made in 1878; now, were the occasions upon which you were down the river near the outfalls in the spring of 1878?—There were a good number of them.

13,180. If they were for the purpose of preparing this Report, they must have been before April; now are we to take it that your visits down the river in 1878 were all before April 1878?—Not all of them.

13,181. Were the bulk of them?—I could not remember that at the present moment.

13,182. I suppose we may take it up to the end of April, that is not the season of the year at which the river as a rule is offensive?—It is not.

13,183. Therefore, as far as your visits are concerned before April, they would not affect the matter? —I was upon the river 10 days in March, four days in April, and six days in May and June.

13,184. All below the outfall or partly in connexion with the toll bridges?—It was partly in connexion with the toll bridges.

13,185. That is no use to me. What I want to know is upon how many days in April you were below the outfalls?—I do not remember.

13,186. Were you down below the outfalls any days between April and when you went down in a steamer in November?—I cannot tell you.

13,187. Now, with regard to the steamer, people, as I understand you, have been alleged to be poisoned when the "Princess Alice" went down?—Yes.

13,188. And then, in consequence of that, the Board sent some members of the Board down in a steamer, and you accompanied them?—I think all the members of the Metropolitan Board of Works went down to see the river themselves, and invited reporters down with them, and I myself went down.

13,189. I rather gathered from you yesterday that the Board of Works satisfied themselves that there was nothing in the condition of the water to poison the people who were immersed from the "Princess Alice"?—I do not think the Board stated that, but I think they instructed their chemist, Mr. Keates, to prepare a report upon the subject.

13,190. Your visit was in November 1878, and the disaster to the "Princess Alice" was upon the 3rd of September?—It was.

13,191. So that the condition of the water in November would not be any criterion of the condition of the water in September?—It would not.

13,192. Upon that occasion, as you stated, you collected the sample from Beckton?—I did.

13,193. What is the size of the sewer there?—It is an egg-shaped sewer, about 2 feet 6 inches high. I think it is a well known sewer, it is the most stinking place I have ever been in in my life, and the foreshore is in the most disgusting condition I have ever seen anything.

13,194. What we want to know is, what kind of smell is it?—A gasey kind of smell, in fact, a heterogeneous collection of smells.

13,195. (*Sir John Coode.*) I should like to know what was the quantity of fresh water which came over Teddington Weir between the accident to the "Princess Alice" and this inspection in November, because the condition of the river would depend in a very great degree upon there being much or little water in the river?—But I think the chemist went down and took samples of water immediately after the disaster.

13,196. What I should like to know is, what was the condition of the river water immediately after the disaster to the "Princess Alice," and between that and the time of Mr. Chatterton's inspection upon the 23rd of November?

(*Mr. Michael.*) That you shall have.

(*Sir John Coode.*) We can get it from the Thames Conservancy, we will go to the fountain head.

13,197. (*Mr. Lumley Smith.*) I am afraid Mr. Taylor's tables are not quite to be relied upon, and that is the reason we gauged the river later on, and that gave it us more accurately; but our records do not begin quite early enough. (*To the witness.*) Now, with regard to this sample which you took upon the 23rd of November 1878, what did you do with that; you gave it to Mr. Keates, did you not?—I handed it round and gave them a smell, and then I passed it on to Mr. Keates.

13,198. (*Chairman.*) That was the sample taken from the outfall at Beckton?—Yes.

13,199. (*Mr. Lumley Smith.*) Which you said smelt gasey?—Yes.

13,200. Now let us come on, if you please, to the occasion when you went down seriously for the purpose of seeing how far you could detect smells coming from the outfalls; one of those dates was in 1879, was it not, or can you give me the date of the first occasion?—The 22nd May 1882.

13,201. Was that the only occasion upon which you put in your float and followed it down the river, testing the smells as you went, or did you do it upon more than one occasion?—I have mentioned one other occasion upon which I did it.

13,202. Can you give me the date of that?—I am not quite sure that I did put in the float any other day to follow it.

13,203. Are we to take it that there was only one

*Mr. G. Chatterton.*

23 May 1883.

occasion upon which you conducted this experiment for the purpose of testing the smells?—I followed the sewage down upon a great number of occasions.

13,204. But you have given us with a good deal of precision what happened upon the 22nd May 1882, and then my learned friend Mr. Bidder put it to you that you had taken other observations afterwards. Are we to take it that that is the one you rely upon, viz., the 22nd May 1882?—I think that was the only day upon which I had a float out, but there was another day upon which I lay in the boat and smelt the water.

13,205. What was the day that you lay and smelt the water?—Upon July 14th 1882; I made some careful observations upon that day: I went down the river from Woolwich to Erith in an open boat, and at Jenningtree Point I noticed that there was a good deal of that bubbling which you see in the Thames; I smelt the water very carefully that day.

13,206. That was the 14th July 1882; now, are the two occasions upon which you made notes of what you smelt for the purpose of this inquiry, as we understand, May 22nd and July the 14th?—And July 27th also. I was on the river a great deal, as I told you, in June, July, and September, but, having done it so fully upon that day, I did not do it again.

13,207. Then it comes back to this, that, as far as precise observations are concerned, what you rely upon are the observations you made on the 22nd May 1882?—I cannot say that I agree with you there; I was upon the river the whole year, and if there were any bad smells I did not smell them; I cannot separate one particular day out, I will take them altogether.

13,208. Then the only occasion upon which you made any careful observations upon the smell of the water and of the shore was upon the 22nd of May 1882?—It was not; those are my notes as I gave them to you; they are practically my proof.

13,209. What I want to know is this: upon May 22nd 1882 you went and made your notes, smelling carefully as you went along, until you lost the smell?—I did.

13,210. Have you the notes now?—No.

13,211. Where are those notes?—I made them a year ago; I do not know where they are now; I wrote my proof, as far as that is concerned, a year ago, and I do not know where those notes are now.

13,212. But did it not occur to you, as being an intended witness here, that it would have been satisfactory to have had those notes?—I do not think so.

13,213. Have you the notes of July?—I do not think I have any notes; I took notes from time to time, and I jotted them down, and they are in my proof.

13,214. When was the proof written, can you tell me that?—A long time ago. My note as regards the observations of May 22nd was written a few days afterwards.

13,215. Have you got it?—I do not know; I dare say it has gone to the Board of Works.

13,216. Have you no original observations now?—No.

13,217. Nothing but your proof which is now before you?—No.

13,218. (*Prof. Williamson.*) I understood you to say just now that in one part of the river you noticed a bubbling of the water; I should be glad to know whether you had occasion to examine any of the mud which was at the bottom at that place where the bubbling was perceived; because, of course, it is known that bubbles are evolved chiefly where organic matter is undergoing active decomposition?—I have noticed a great deal of bubbling in the Thames, and anybody can notice it who goes down there on a summer's evening; you will notice it in Jenningtree Point, you will notice it in Erith Bight; as far as Long Reach you will notice bubbling; and what I wanted to satisfy myself was, was there any nuisance from those bubbles. I supposed they were in some sort of way the result of putrefaction, and I got my nose as close to the surface of the water as I could, but I could not perceive any odour from them. When I have been sounding, I have noticed them very much, and I have also noticed bubbles coming from a sandy bottom. I have been told it is absurd, that bubbles cannot come from a sandy bottom; but I disagree with that.

13,219. Did you take occasion to examine specially the mud underneath that part of the surface in which the bubbles appeared?—Yes, I did.

13,220. With what result?—I did not notice any difference from the ordinary mud upon the banks.

13,221. (*Dr. Stevenson.*) You did not collect any of those bubbles for the chemist, did you?—No, I did not, I tried to do it, but I could not do it.

13,222. (*Chairman.*) You stated that you saw them more particularly in Erith Bight, where the slack water goes?—Yes.

13,223. Where you say no sewage goes?—I did.

13,224. It might be Erith sewage, by the way, might it not?—I do not say that. As a matter of fact, I do not think the bubbles are any harm to anybody.

13,225. It depends upon what they come from?—I have examined them, and smelt them; there is nothing in them; anybody can go and see the bubbles, it is a matter of common observation.

13,226. (*Mr. Lumley Smith.*) You think nobody ought to find fault with them?—I never heard anybody find fault with them; I never heard anybody say they smelt them, and I do not believe they ever did.

13,227. You think bubbles are no nuisance, and that a nuisance does not arise from them?—I do.

13,228. Do you then entirely disbelieve the statement that patches rise from the bottom and give off odours?—I do not believe it; if you will point to the passage which states that, I will tell you what I think of it.

13,229. Now upon the 27th of July what was the condition of things when you lay down and smelt the water; whereabouts was that?—From below Jenningtree Point to above Crossness.

13,230. How came you to be out there; what were you doing upon that occasion?—Upon that occasion I went down with one of the chemists to take samples.

13,231. But you were coming up stream upon that occasion, how came you to be coming up stream?—I was coming back in the tug.

13,232. In what state of the tide was that?—That was upon the ebb.

13,233. Now, with regard to May 1882, in which month you took your careful examination, I just want to see with a little more detail what you did; you went, as I understand, in a boat to the opening of the outfall?—I did.

13,234. And waited for the outfall being opened at high water?—I did.

13,235. How far off were you from the outfall then?—I was just under the apron.

13,236. Then of course the sewage would come immediately all round you?—I shall never forget it.

13,237. As you tell us, it is a smell that is like no other smell?—It is a smell that is like no other smell; it is very disgusting.

13,238. You did not stay there longer than you could help?—I stayed there to put in the float.

13,239. And then you followed the float?—I did.

13,240. And that floated away?—Yes.

13,241. Then how soon after the outpouring of the sewage commenced did you put your float in?—Immediately.

13,242. Did you allow it to take its own course?—Yes; I did.

13,243. And followed it down the river?—I simply wanted to follow some portion of the sewage as it were.

13,244. And, in fact, you did follow the float down the river?—Yes; I did.

13,245. Keeping with it, I suppose?—Yes.

13,246. This was at the time of high water?—Yes.

13,247. And at the time when the bulk of sea,

water, the water which had come up from the sea would be at the highest opposite the outfall?—Yes.

13,248. And when whatever was put into the water would go into the largest quantity of water?—Yes.

13,249. Does it not occur to you that this was rather, for the purposes of your case, a favourable opportunity to test the sewage coming out of the outfall, because you would be following the very first spoonful of sewage that went out from the outfall, which in its turn would be going into the largest possible quantity of unpolluted water. In the first place, are my facts correct, that you are taking the very first outfall of sewage into the largest bulk of unpolluted water?—I do not think they are quite correct.

13,250. Why not?—Because I was there some time after high water.

13,251. But it was immediately that they opened the outfall?—The high water that day was one minute past five at London Bridge, and high water down there would be about 25 minutes to five. A float being put in there at Barking (as everybody knows, at high water it is slack water), it takes a long time at first for the float to move a little bit; it was a quarter to six when that float was opposite the reservoir. I only wish the float had gone away sooner because it kept me out in that place longer than I wished. I was there at five o'clock, and it was a quarter to six before it moved away, so that I was there three-quarters of an hour before it moved away.

13,252. But do you say the sewage was not moving away?—My float was not moving, but that is no reason why the sewage should not be moving; the sewage comes out and spreads itself out in the river like a fan, a very distinct line of demarcation being established between the sewage and the rest of the water. If my float had gone out and got into the outside line of the sewage, and got the start of the sewage, I would have been all right,—the fact was, the sewage was beginning to be discharged at five o'clock, and I was there for three-quarters of an hour.

13,253. Now you are giving us particular minutes, and we should like to have your original memoranda; were they sent in to the Board?—I do not know whether they were or not.

13,254. Does not it occur to you that it would make a great difference, as regards the mixing, whether you started with the sewage at high water, or whether you began when the sewage had half flowed out?—No, I think I was there at the most unfavourable time for the sewage, because in the first half hour of the tide the first four feet of the sewage goes off; so I worked in an abnormally large volume of the sewage; after that it falls away and discharges as the tide falls.

13,255. (*Chairman.*) Does more come out at high water than afterwards?—Yes, it must do so.

13,256. At the first discharge?—Yes, I have never gauged it, but I should think it must be.

13,257. (*Mr. Lumley Smith.*) The fact remains the same, that you took this observation going down with the float, which was put in when the outfall first commenced, and at high water?—Yes.

13,258. So that the quantity of water which comes up from below would be the highest possible, and you would get away from the outfall with the very first quantity of sewage which came out?—I told you I got away after three-quarters of an hour's discharge.

13,259. (*Mr. Abernethy.*) The high water would be the period of minimum head of the reservoir, would it not?—No. I think the level of the weirs of the reservoir is 16·50 above Ordnance datum; that is 4 feet of high water.

13,260. But the period of high water was not the period of the minimum head in the reservoir; the head would increase as the tide fell, would it not?—I should say that at high water it would fall more rapidly.

13,261. (*Chairman.*) What is the outlet, is it through some bore or culvert?—Through a culvert.

13,262. Not over a lap as it were?—No; there are penstocks in the reservoir; they are all lifted at nigh water, and the sewage rushes out at first, and when it reaches a sufficient level, then it falls gradually with the tide, as Sir Joseph Bazalgette told you yesterday, four hours after high water, and it ought to be three. It has got a greater head to start with, and it runs that off, and then discharges more slowly.

13,263. (*Mr. Lumley Smith.*) However can you say there is nothing in my suggestion; I say there is the maximum of water to dilute, and that you would go off with the van of the outfall?—I meant to take it in every way that would be against the outfalls, and I think I succeeded.

13,264. However you may have taken it against the outfall, the question is whether you succeeded?—I did my best to make it fair, and I think I succeeded.

13,265. Have you made any note of the direction of the wind?—There was hardly a puff of wind; the wind was south, south-west, and as the afternoon came on there was hardly any wind; it was a lovely afternoon.

13,266. Was the water quiet?—Yes, it was as smooth as glass.

13,267. You told us that after you had lost any sense of smell from the water, that if you shook it in tubes you detected a smell then?—Yes, you are quite right; when the sewage comes out first of course you can smell it.

13,268. I think I am correctly reproducing what you said yesterday; you got to a certain point where you ceased to smell it, when you sat in the boat?—Yes.

13,269. But that when you shook it up in a tube you could smell it?—Yes.

13,270. Now I will ask you this: I suppose the passage of a screw steamer would have the same effect as shaking the sewage up in the tube, would it not?—No, because when the screw of a steamer shakes it up the smell has some space to disperse into, but when you shake the stuff up in a test tube, and put your thumb upon the top, and then smell it, you get the first whiff of it.

13,271. Perhaps your sense of smell from having been so long in the smell was not so acute as if you had come from the sea to Jenningtree Point, when you would have smelt it?—I do not think it was at all impaired.

13,272. (*Sir John Coode.*) You told us yesterday that you thought the effect of a screw steamer was very much like shaking a test tube?—I certainly put the test tube first and the steamer afterwards; still it is a capital way to smell it, to sit in a boat behind the screw of a steamer.

13,273. (*Mr. Lumley Smith.*) You told us that the last time you could smell it was below Jenningtree Point?—It was some distance below Jenningtree Point.

13,274. Was that in the water or when it was shaken in a tube?—It was when it was shaken in the test tube; it was some little distance below Jenningtree Point.

13,275. You said that at Bow Creek you saw a large quantity of sewage coming down; when was that?—The 3rd of July at 9 o'clock.

13,276. Have you any memoranda of that?—I took two samples and sent them to the chemist.

13,277. There is in Bow Creek a storm overflow is there not, belonging to the Metropolitan Board of Works?—Yes, somewhere up Bow Creek, I believe, there is.

13,278. Did you go up Bow Creek to see where the sewage came from?—No; but I am pretty sure that it came from the West Ham sewer.

13,279. I am rather trying to divide your evidence into what you know of your actual knowledge, and what you derive from conclusions that you draw. Did this make any considerable stream out into the river?—It was getting on towards low water; it was the ordinary flow of Bow Creek.

13,280. Did this make any considerable smell in the

*Mr. G. Chatterton.*

23 May 1883.

river?—It was a cold morning, and you could not smell it.

13,281. But did it make any considerable appearance in the river?—I was going down taking samples, and I noticed the sewage coming down Bow Creek, and I stopped the boat and went up the creek as far as the Thames Ironworks, about 200 yards up the creek. I noticed the sewage or dirty water coming down, and I took samples of it, and sent them to the chemist. I think there were about 3 feet 6 inches of water there.

13,282. (*Sir John Coode.*) Do you mean in the creek or that the sample was taken 3 feet 6 inches under the surface?—No, in the creek. I think the sample was taken 2 feet below the surface.

13,283. (*Mr. Lumley Smith.*) Did you meet any stream coming out into the Thames; could you follow it for any particular distance?—I did not.

13,284. Now with regard to pumping from barges, you told us that upon the 3rd of July, opposite Blackfriars Bridge, you saw a barge pumping out something; do you attribute importance to that?—I do not, except that in the Thames there is nobody to look after the vessels; they put what they like into the river, and I do not think it is right that people should go opposite the embankment and pump what they like into the river.

13,285. That is what we may call *alia enormia*, that other people foul the river besides the Metropolitan Board of Works?—Yes.

13,286. You went on board a Dutch boat, you say, in August?—I did.

13,287. Now, you are aware that 1882 was an exceedingly wet year, that the river was exceedingly sweet except in one particularly part of the year 1882?—I do not remember that.

(*Chairman.*) We may take judicial notice, I think, that last year was a wet year.

13,288. (*Mr. Lumley Smith.*) You gave us some information to-day about the floats; you say you made some float experiments, and none of the floats went into Erith Bight?—No, none of the special ones. On one occasion following a float it did traverse Erith Bight, but that was one of the float observations made later in the year.

13,289. When was that?—My men were doing it; that was the time when the corporation float experiments were going on.

13,290. You were watching them?—I was watching them, and they were watching us.

13,291. What were the float observations about which you are giving evidence upon to-day; when were they taken?—They were taken during the summer.

13,292. For the purpose of this inquiry to satisfy your own mind?—Yes.

13,293. Were they for the purpose of this inquiry?—Yes.

13,294. Were they made for the Board of Works?—Yes.

13,295. I suppose you made observations of them?—I did.

13,296. Where are they?—I do not know.

13,297. But this is an inquiry in which one likes to be as precise as possible; where are the memoranda that you made of those observations?—I have them all in my mind. I was watching Mr. Birch's observation. I know the set of the tides perfectly well, and I did not write them all out.

13,298. But you made certain memoranda for the purpose of the Board of Works; where are they?—One of the float observations would be watching the sewage flow on the 22nd of May. I say I watched the set of the current in those reaches most carefully and attentively, and these which I have given are the result of my observations, watching them: and I give them to the Commission for what they are worth.

13,299. (*Chairman.*) These are your observations at the time, and you made notes at the time, I presume?—Yes, I did.

13,300. But you have not got them with you?—I have not preserved them.

13,301. Then I should advise you another time to preserve them, because you might at any time be called upon to justify the observations you made in your report?—I am sorry I did not keep them.

13,302. (*Mr. Lumley Smith.*) Now what did you do with them?—I do not know.

13,303. Now, with regard to the float experiments you have been telling us about to-day, they were float experiments for the purpose of seeing which way the sewage went?—I was down the river when the corporation were making their float experiments.

13,304. But that was not in the month of May 1882?—No, that was in November or October.

13,305. I want to know when you first reduced into shape your observations upon the current floats?—I do not believe I ever reduced them. I made them, and I have them all in my mind.

13,306. When did you first reduce them to shape?—I did not so reduce them; they had never been put into shape until they appeared in my proof.

13,307. When was that?—Some time before Christmas.

13,308. And you have no memoranda which show the result of your observations except what you have put in your proof?—No, I have not, but I have practical experience in it.

13,309. You can give us no memoranda?—No, I cannot. If you doubt my observations, the only way to do it is to go and see it yourself.

(*Chairman.*) Do not you see what is the effect of that answer? It amounts to this, that all I have said is of no use.

Cross-examined by Mr. Beaumont Morice.

13,310. You have told us that there is no difference in the mud along Erith Bight; is that so?—There is a slight difference in the colour I think, but there is no great difference in the mud near Erith Causeway.

(*Sir John Coode.*) Do you mean as between one part of the bight and another, or as within the period between 1877 and 1882?

(*Mr. Beaumont Morice.*) As between one time and another?

(*Witness.*) I thought the question referred to between one part of the bight and another.

13,311. (*Mr. Beaumont Morice.*) You have no knowledge of Erith before 1877, have you?—I have this much knowledge: I made a boring of the mud bank in 1878 at Erith 10 feet deep. I drove a tube into the river 10 feet deep.

13,312. But before 1877 had you any knowledge of the state of the mud in Erith Bight?—I had not.

13,313. During the period from 1877 to 1882 how often had you been yearly upon the river at that spot?—I was there more last year than at any other time.

13,314. But that is not an answer to the question. How often have you been upon the river at that spot?—I cannot divide it up.

13,315. Let me take it by years, beginning with the year 1877?—In 1877 I was not in Erith Reach. I have not spoken of the Erith mud in 1877. I have spoken of the Long Reach mud, not of the Erith mud.

13,316. But you stated, in answer to my learned friend Mr. Bidder, that the state of the mud in Erith Bight was of the same description as the mud in other places?—No; I stated the condition of the mud in Long Reach.

13,317. Then you have no experience in 1877 of the mud of Erith Reach?—No; I took a boring of the mud in 1878 in Erith Reach.

13,318. Then in 1878 do you remember how often you were there?—I do not remember how often I was there.

13,319. Were you there at all?—Yes; I have told you I took a boring there.

13,320. Were you there more than once?—I was there a dozen times between Purfleet and the outfall.

13,321. Have you any notes of how often you were there in 1878?—No, I have not.

13,322. In 1879 how often were you there?—I was very little in Erith in 1879. I was principally in Long Reach.

13,323. And in 1880?—In 1880 I was not very much there either.

13,324. And in 1881?—In 1881 I was not very much in Erith. I have not mentioned Erith in any one of those years.

13,325. Were you there at all?—Yes, I was.

13,326. In 1882, last year, were you there?—In 1882 I was. I was there last year a great deal.

(*Chairman to Mr. Michael.*) I do not know whether you will bring forward some of the inhabitants to say that they do not smell this smell that has been so much talked of.

(*Mr. Michael.*) I cannot say as to that, but we shall have some medical evidence.

(*Chairman.*) Mr. Morice is asking these questions with a view to see what knowledge Mr. Chatterton has generally of the subject. If a man who lives upon the bank of the river were examined, and could say, "I live there habitually and do not not smell this smell," that would be a different thing.

(*Mr. Beaumont Morice.*) I do not think my learned friend can do that.

(*Chairman.*) I assume Mr. Michael, judging from his look and gesture, will say that all Erith is against him; in that case it does become important to examine into the knowledge of a gentleman who is not locally prejudiced.

13,327. (*Mr. Beaumont Morice to the witness.*) You say you were there a good deal last year; how often were you there?—I was there in May. I was there in June. I was there in July. I was there in August. I was there in September. I was there in October, and I was there in November. I was down the river in all 59 days between May and November; and on about 45 out of those days I was past Erith. I sounded Erith Reach and Erith Rands last autumn. I took a great number of sections there, which will be put in; that alone took me a great number of days, and I lived down at Erith when I was doing them.

13,328. How long did you live at Erith?—Three or four days at a time.

13,329. (*Sir John Coode.*) Were any of these sections taken at Erith in the immediate locality?—Yes; Mr. Law will put them all in.

13,330. (*Mr. Beaumont Morice.*) With respect to your visit in November after the Princess Alice accident, you know as a fact, do you not, that the river is generally in a better state in November than in the preceding month?—It depends upon whether there is any land water that comes down.

13,331. But the river is generally in a better state in November?—Yes, certainly, the temperature is lower.

13,332. (*Sir John Coode.*) And there is a greater quantity of water coming down?—Yes, certainly, as a rule.

13,333. (*Mr. Beaumont Morice.*) Have you ever been in the neighbourhood of the river at Erith in August and September?—I was down there almost all August and September last year; my soundings were almost all done in August and September.

13,334. At what part?—From half a mile above the Corinthian Yacht Club to half a mile below Messrs. Easton and Anderson's works. I went there intending to make a survey of the river from Jenningtree Point to Dartford Creek, but I was not able to do so; I had not time.

13,335. (*Sir John Coode.*) Are not Messrs. Easton and Anderson's works somewhere to the eastern part of Erith?—Yes.

13,336. Almost immediately to the eastern part of Erith?—Yes, I took something like 44 cross sections of the river.

13,337. (*Mr. Beaumont Morice.*) Have you taken any soundings in Erith Bight proper?—Yes, I tell you I took about 44 cross sections of the river between those two places which I named.

13,338. But have you made any between the pier and the Corinthian Club-house?—Yes.

13,339. How many have you made?—Sixteen.

13,340. How many days were you taking soundings between those points?—I really could not tell you unless I referred to my level book. My sections were about 400 feet apart. I do not know what the distances are exactly.

13,341. Could you produce the level books, because I should like to know how many days you were taking soundings between Erith pier and the Corinthian Yacht Club-house?—I will give you that information, I have no doubt.

13,342. (*Mr. Balfour Browne.*) That is to say you will produce the level books?—I will produce the books of the soundings between Erith Pier and the Corinthian Yacht Club-house.

13,343. (*Mr. Beaumont Morice.*) You will give us the book in which you made those entries?—Yes, I will.

13,344. Do you know the character of the mud between those two points?—Yes, I do.

13,345. Is there any difference, judging without going into it chemically, between the ordinary mud in other parts of the river and that mud?—I do not think so.

13,346. Have you ever been on Erith Pier at ebb tide?—I have.

13,347. And seen the deposit?—I have.

13,348. Have you been down the causeway?—I have.

13,349. Do you mean to say the mud there was the same as in other parts of the river?—I do not think there is any difference. I am only speaking as a casual observer, but I think you may take it from me, that you will have chemical and other evidence upon that point which is more valuable than mine.

13,350. I ask you, if between those two points, Erith Pier and the Corinthian Yacht Club-house, there is any difference between the ordinary character of the mud and that in other parts of the river?—There is a slight difference which I think can be detected by the eye, between the mud at the Corinthian Yacht Club-house and the mud at Erith Causeway—the mud at the Corinthian Yacht Club-house is more compact and of a slightly darker colour than the mud at Erith Causeway—I take it that the reason of it is, that there is a stronger current at the Corinthian Yacht Club-house than there is at the Erith Causeway, and that it has washed away the finer particles of the mud, more than it has at the Erith Causeway. There is a difference in the texture of the mud if I may call it so.

13,351. You know upon the causeway there is a large deposit of mud?—Yes, I do; caused by the bad construction of the causeway, and generally acknowledged by the Erith people to be so.

13,352. Do you know that the deposit is upon both sides of the causeway?—I know that upon the lower side of it, it is sometimes from 2 feet to 2 feet 6 below it—it acts the part of a groyne while on the other side of it, it is upon the level of the causeway.

13,353. Do you know that upon the lower side there is a deposit of from 6 to 8 feet of mud?—I should not be surprised if there were. I made a boring of 10 feet.

13,354. You sounded and therefore stirred it up?—I have driven a rod into it.

13,355. Do you mean to say after that, that it is what you call the ordinary kind of mud?—Yes, ordinary river mud; there is no difference between that and ordinary river mud.

13,356. Is it slimy?—No, I do not think it is.

13,357. You know Mr. Beadle who has been

*Mr. G. Chatterton.*

23 May 1883.

examined here, do you not?—I know there is a Mr. Beadle who lives there.

13,358. But you know he gave evidence here, and you heard him examined here?—I was not here the first day, and I do not think I heard him examined.

13,359. Do you know that Mr. Beadle referred to this mud as a slimy greasy mud?—I do not know that. I do not think there is any difference in it from ordinary river mud.

13,360. Have you ever found any smell from it?—I have, just where the Erith outfall comes out. I have noticed the Erith outfall, but I have not smelt that mud.

13,361. When you were sounding this mud by the causeway, did you find any smell when you brought up your rod?—No, nothing more than ordinary river mud, all mud smells a little.

(*Chairman.*) I do not understand Mr. Chatterton to be a witness called by the Board for the purpose of showing the condition of this mud.

(*Mr. B. Morice.*) He has stated that there is nothing of a sewage or bad smell in the mud.

(*Chairman.*) He rather himself declined being that witness—he says "If you ask me, I will tell you what "I think about it, but there are other witnesses more "competent to speak about that than I am." Is that so?

(*Witness.*) Yes, I am not a chemist nor a microscopist and there are such who will be called before you.

13,362. (*Mr. B. Morice.*) Then I will go to another point; you have told us about the different factories?—Yes.

13,363. Can you tell the different smells of those factories?—I cannot distinguish every one of them, but you can put them into groups; they are very marked. I can tell, for instance, the smell of the fish manure from the others.

13,364. Speaking generally, you can tell the different smells?—Yes.

13,365. How often have you had an opportunity, by being down there, of judging between the different smells?—Every day that I was down there, when the wind was favourable, I smelt the factories from one side or the other.

13,366. During the period you have told us?—Yes.

13,367. You smelt them when you were upon the river?—Yes, and upon the land.

13,368. Have you ever smelt the sewage smell at the same time?—No.

13,369. If there had been any sewage smell you would probably have been able to distinguish it, would you not?—Upon my word, I cannot tell you that; I think I could tell the smell of sewage just below the outfall from the smell of the factories; certainly I could. Sometimes they are a little alike, but with practice your nose can detect the difference.

13,370. Therefore if persons resident in the locality say that they can distinguish between the two you would agree with them?—Yes, if they have had much experience.

13,371. You told us that the sewage smell was a local smell, and was disgusting?—Yes, but you must remember that when I told you that it was disgusting it was when I was in a boat in the middle of the sewage of all descriptions, but when you are out on the river 200 yards from the outfall there is a very different smell from the smell at the outfall.

13,372. You have never smelt that smell, though you have smelt the factories?—I have smelt the factories a great number of times.

13,373. Now with regard to the sewers of Erith; you have heard the evidence given by the surveyor to the Local Board?—I have.

13,374. Do you know how many houses there are in Erith?—I think I did, but I forget now.

13,375. I will remind you that there are 1,883 rateable houses; do you know how many of those are drained into the Thames through these sewers?—I know it was given in evidence; I do not remember the figure.

13,376. It is 507?—I have read Mr. Easton's Report upon the sewerage of Erith.

13,377. Will you kindly bear in mind that I am upon the evidence of the surveyor of the Local Board?—I do not think that the evidence of the Surveyor of the Local Board agrees with Mr. Easton's Report.

13,378. But the Surveyor of the Local Board is an official person, and he has given his evidence, and his statement is that there are 507 houses drained into the river through this sewer; are you prepared to say that the sewage of these 507 houses will cause the nuisance you have been speaking of to-day?—I am prepared to say that the sewage of 507 houses, being concentrated as it is, will cause a nuisance when discharged upon the middle of that mud; that is to say, if you were to discharge it in the middle of this table or this room it would be very disagreeable for everybody sitting round it.

13,379. Do you mean to say that the drainage caused by these 507 houses would amount to the nuisance you have been referring to to-day, and would account for the complaints of the people of Erith?—I say that the sewage of those 507 houses would account for the complaints of those men who were excavating a channel for Mr. Beadle, and I never said anything more than that.

13,380. Now you stated that last year, when you had such experience of the river, there was no smell from the river?—No.

13,381. Was there no smell from the Thames in Erith Bight last year?—No, I am positive of it.

13,382. That there was no smell?—That there was no smell, and everybody I talked to in Erith said the same.

13,383. And you say there was nothing offensive?—Nothing at all.

13,384. Nothing offensive either in the smell or the mud?—No, I say that last year I rather enjoyed myself there, except when I was in the middle of the sewage. Erith bight is a very delightful place to spend a summer in; you may laugh, but it is perfectly true; there is a very nice yacht club—a most popular yacht club there.

13,385. (*Chairman.*) Erith is a very nice place, is it not?—Yes, and there is a very nice yacht club there; it is becoming a very popular club. I have been invited frequently to go down there yachting on Sundays, but having been engaged all the week I prefer to spend my Sundays at home.

13,386. (*Mr. B. Morice.*) Do you know that there has been a tendency to silt up this place where you say the flushing takes place?—No doubt there is a tendency to silt up; but with regard to that excavation at the coal wharf that is quite recent.

13,387. In the examination of Mr. Beadle by the noble Chairman, he was asked, "But you said that it "was not necessary to do so a few years ago?" to which he replied, "Not as we must do it now; we "have to keep a gang of men sweeping it night and "day;" and in the previous question he was asked, "Was it only the last year or two that you have been "obliged to keep the place clear? (*A.*) No, we "always had a man in there to look after it; but "these last two years it has been almost impossible "to keep it clear"?—I quite agree with every word he says, and I can explain it. The foreshore low-water line has gone out at Erith Causeway an enormous distance within the last few years; every word that was said about that is perfectly right, and it is exactly what must take place on account of the slack water.

13,388. There is an increasing deposit of this mud?—Yes.

(*Chairman.*) I do not know what you mean when you say that the low-water mark has gone further out.

(*Mr. B. Morice.*) There has been an increased deposit of mud which sends the low-water mark further out.

(*Witness.*) But that is above the pier. Below Erith pier the foreshore has not gone out an inch since 1833, comparing it with the chart; but above Erith pier it is going out to this day, and I do not know

how far it will go out. Deposit at slack water must take place.

(*Sir John Coode.*) I understand this arises from dredgings upon the opposite shore?—I do not care to go into that; but I have many observations, and Mr. Law will put them in.

(*Sir John Coode to Mr. B. Morice.*) That is the point which is between you. You contend that that is due to the increase of the sewage, while the other side contend that it is owing to the dredging upon the opposite side.

(*Mr. B. Morice.*) And the question is also, not what caused it, but also what it is.

(*Sir John Coode.*) Certainly.

13,389. (*Mr. B. Morice to the witness.*) Are you aware that in the report upon the drainage system in 1857 it was stated that Erith reach would not be a good place to receive the sewage because it would silt up?—I am not.

13,390. Do you know as a fact that the accumulation in the bight near the Corinthian Yacht Club house is largely composed of sewage?—I know as a matter of fact that it is not.

13,391. You have heard the evidence of the man Lee, who is the man in charge of the yacht-house?—I have; he said it was "that which came from the "human frame." It is the greatest nonsense that any man ever talked about—he lives there, a great strong healthy fellow, with a lot of little children always playing about in the mud; it is absurd.

13,392. But he is living there, and should know all about it?—No doubt he should, but he talks about its being "what comes from the human frame"; it is the greatest nonsense in the world; it is just what does not come from the human frame.

13,393. You remember that Mr. Lee stated that some of his children had illness?—I do not remember that, but I know him well; I used to land there.

(*Chairman.*) How do you cross-examine this witness upon that footing?

(*Witness.*) It is the place where all gentlemen get into their boats, and leave their boats; it is a very nice place.

13,394. (*Mr. Beaumont Morice.*) You say there is no sewage in that bight?—The chemists can give you evidence about that.

13,395. But speaking popularly, as an ordinary observer?—Nobody speaking truly could say that there was sewage in that bight. Speaking ordinarily it will not smell of sewage.

Re-examined by Mr. Michael.

13,396. A very large number of samples of mud were taken for the former inquiry, and they were analysed by chemists?—They were.

13,397. And you took a large number of samples for determination whether the alleged sewage at those various places was sewage or not?—I did; I took a great number.

13,398. With respect to the time over which your examination of these various matters extended, how long last year did you practically live upon the river?—I was down there 59 days, between the months of May and November.

13,399. Had you a steamer?—I had most of the time.

13,400. Having made those observations, when were they reduced to writing?—Immediately after they were made.

13,401. And is this the proof which you have before you of observations which were made at that time?—It is.

13,402. (*Mr. L. Smith.*) Those are not the original observations?—No, not the originals.

13,403. (*Mr. Michael.*) As I understand, except these you only have your level book?—Yes.

13,404. Which you will produce here?—Yes.

Examined by the Commission.

13,405. (*Chairman.*) There is a question I wish to ask you upon which you have expressed an opinion. I understand you to say that there is what you call slack water always opposite to Erith?—Always at three hours after high water.

13,406. And you say the tide does not flow into it as it is flowing down the river?—No, it is coming by the point.

13,407. But when it is coming up the river, coming back, as it unfortunately does, diluted no doubt and mixed, but still when it comes back would it not flow into the bight?—I have not made any observations upon the flood tide.

13,408. But cannot you answer me?—I have no doubt it would go into the bight.

13,409. Then the sewage would be brought into the bight, would it not?—The composition of the banks along there is exactly the same as of the suspended matter in the water.

13,410. But that is no answer to the question—it is giving evidence upon a point upon which you disclaimed your competency, but it would be true, would it not, that the return sewage would come into Erith bight?—Yes, I have no doubt that the water coming up the river would.

13,411. (*Sir John Coode.*) Will Mr. Law's section show us how much the bed of the river has been dredged of late years?—He has got as much information as there is upon the subject; he has got comparative sections for the years 1833, 1861, 1879, and 1882.

13,412. It is rather important for the Commission to know what are the facts, in order that they may know what they should consider to be the proper weight of this contention as to the effect of this dredging in causing this deposit. It is contended, I believe, on behalf of the Metropolitan Board of Works, that this advance in the low water line is due to dredging upon the north side?—Yes.

13,413. And upon the other side it is contended that the deposit is caused by sewage, which you deny?—Yes, that is so.

(*Mr. Michael.*) We had a large number upon the former inquiry, and we have more now, of observations to show you the alterations in the shore, owing to the alteration of the sectional area. I think we shall be able to produce before you a series of contour plans which will show the periodical alterations of the river.

(*Mr. B. Browne.*) We want the level books put in, and the observations of 1877 and 1882.

(*Mr. Michael.*) They shall be put in.

The witness withdrew.

Dr. Theodore Maxwell called in and examined.

13,414. (*Mr. Michael.*) You are a Doctor of Medicine of Cambridge University?—I am.

13,415. And Bachelor of Science of the London University?—Yes.

13,416. And a Fellow of the Royal College of Surgeons, Edinburgh?—Yes.

13,417. And also a Fellow of the Chemical Society, and a holder of the Cambridge University Sanitary Science Certificate?—Yes, I am.

13,418. Have you for five years resided at Woolwich?—I have.

*Dr. T. Maxwell.*

23 May 1883.

13,419. Where does your practice extend over?—All over Woolwich and Plumstead.

13,420. (*Chairman.*) As practising medical man?—Yes.

13,421. (*Mr. Michael.*) Among what classes do you generally practise?—All classes. I have a good many club patients which comprise the working classes, and men who work in the arsenal and the different factories in the neighbourhood. I also attend many families of tradesmen and of officers, soldiers, and army pensioners.

13,422. And the river-side people who are working upon the river?—The arsenal is upon the river and a large number of people live very near the river; there are no houses actually upon the river side in Woolwich itself. I have sometimes attended people who live in North Woolwich, but I could not say that my practice extends to North Woolwich.

13,423. With respect to the diseases of a zymotic character, what do you say first with regard to typhoid fever and its prevalence in the district?—I have seen exceedingly little of it.

13,424. If it were present according to your experience would you be likely to see cases of typhoid fever and to know of it?—Very likely indeed. I cannot conceive of its being particularly prevalent without my knowing of it. During the five years I have been there, I have had in my own personal practice just three cases of undoubted typhoid fever.

13,425. Do you know what is the result of the practice of other medical practitioners in the district.

*Mr. L. Smith* objected to this question.

*The Chairman* allowed the question to be put.

(*Witness.*) I have seen one or two cases perhaps in consultation or when acting for some other medical practitioner which really did not occur in my own practice.

13,426. (*Chairman.*) You are of course upon friendly terms and communicate with the other medical gentlemen?—Yes.

13,427. And you hear from them the state of the place generally?—Yes, I do.

13,428. And you do not hear much talk about typhoid fever from them?—I do not.

13,429. (*Mr. Michael.*) With respect to diphtheria, have you had any cases of that?—I have seen since I have been at Woolwich, one case of undoubted diphtheria in my own practice; two or three weeks ago there was one at Shooter's Hill. I have also seen in consultation two other cases in the lower part of the town, and I have had under my own care a case which I believed to have been diphtheria, but about which there was some doubt, that is all I know about diptheria.

13,430. How far is Shooter's Hill from the river?—About two miles.

13,431. With respect to other diseases of the same class, scarlet fever and other diseases of that sort, are they prevalent according to your own experince?—I have nothing to remark about them. I do not think they are peculiarly prevalent, and I do not think they are less prevalent than they are elsewhere, but it would be extremely difficult to say. These include classes of cases in which doctors are called in and some in which they are not, according to people's fancies or to their means, so it would be extremely difficult to say whether there are more or less cases at Woolwich than in other places. I have no reason for thinking they are either more or less.

13,432. Has your attention been directed to the alleged presence of the sewage in the river, so that you could trace those cases of disease to the sewage in the river?—I know it is said that there is sewage in the river, and I know from personal experience that the river smells badly.

13,433. Have you any reasons to trace the diseases to the sewage?—I have been unable to do so.

13,434. (*Sir John Coode.*) Have you been able to trace the disease to any special cause?—The first case of typhoid fever was that of a clerk engaged in London, and I believe from what he said that the typhoid fever arose from defective sanitary arrangements in his office in London. I looked at his house in Woolwich, and I have no reason to think it came from there; and the only conclusion I could come to was, that it arose from the state of his office in London. Then, as to the other two cases I had in my own practice, they certainly did occur close to the river; they were the cases of a working man and his son, both of whom worked at some works upon the other side of the river, viz., at the Beckton Gasworks, and from inquiries I made of them at the time, the conclusion I came to was that the closet arrangements for the working population of Beckton were exceedingly defective. I knew of no other cases in the neighbourhood at the time, and the conclusion I came to was, that it had been caught from some cause or other over at Beckton.

13,435. Were those the only cases that you heard of, the clerk and the two men employed at Beckton?—I have had no others in my own practice.

13,436. (*Dr. Stevenson.*) Were those simultaneous cases, the father and the son?—They were almost simultaneous; the disease was almost evidently caught at the same time and place.

13,437. (*Mr. Michael.*) What is the general health of the people of Woolwich?—Very fair; it is, as far as my practice enables me to judge, as healthy as most places.

13,438. Have you ever been able to form any opinion as to the river exercising any injurious effect upon the health of the district?—I have never had any reason to think that it does so, and I have smelt it often enough.

13,439. Do you often cross the river yourself?—Sometimes I cross it frequently; sometimes a month goes by without my crossing it.

13,440. Do you exercise your practice constantly close to it?—I am constantly close to it; I was across it pretty often last summer, and I do not recollect noticing the smell very decidedly.

13,441. (*Sir John Coode.*) Do you live near the river?—No; I live upon the common, which is about a mile from it.

13,442. (*Chairman.*) And it is upon high ground?—It is on high ground.

13,443. (*Mr. Michael.*) But, as I understand you, your practice extends to the riverside?—Yes, it does.

13,444. Therefore, if there were any injurious influence, you would be likely to know of it?—I should be almost certain to know.

13,445. (*Chairman.*) At what distance from the river can you smell it; can you smell it at any distance, or only when you are upon the river?—I do not think I have ever smelt it except when I have been upon it, crossing in a ferry boat.

13,446. (*Sir John Coode.*) Have you ever smelt it at your own house?—There are manufacturing smells which I can clearly distinguish at my house, but I should not like to say that I have smelt the sewage there.

13,447. Some of the manufacturing smells are very strong indeed, are they not?—They are very strong indeed.

13,448. (*Dr. Stevenson.*) To what, in your opinion, do you attribute the smell of the river?—I have always supposed it was sewage in the river.

13,449. The smell reminds you of sewage?—Yes, I think it does.

13,450. (*Chairman.*) It is such as you would expect a sewage smell to be?—It is.

Cross-examined by Mr. L. Smith.

13,451. These two men you have referred to worked at Beckton; can you tell me the time of the year when they had that typhoid fever, and what year was it to begin with?—It was about three years ago. I cannot tell you whether it was in December or January; it was in the winter time. It was not in the summer I am positive.

13,452. They would have to cross the river twice a day, I suppose, to their work and back again?—Yes, they would, certainly.

13,453. You have told me, and I suppose it is the fact, that a great many of the poor do not call in doctors unless the illness is very serious?—That is so, only you must recollect that a large number of the patients I attend belong to clubs, and, therefore, they have the opportunity of calling me in for nothing.

13,454. With regard to scarlet fever, to which you have referred, is there a good deal of scarlet fever that goes on without medical men being called in?—I think there is not much, but there would be a good deal of measles. Many people have children with measles, and never think of sending for a doctor.

13,455. And, I suppose, *a fortiori* with diarrhœa?—Yes.

13,456. You heard Professor Corfield examined, perhaps. He seemed to think that the injurious effect of the river would show itself principally in scarlet fever, measles, and diarrhœa; would you agree with that?—I should not like to give an opinion about it.

13,457. Last year we have heard the river did not smell so much as on previous occasions?—I did not notice it particularly last year.

13,458. Have you practised elsewhere, or was this the first place you have practised in?—I practised in Hanwell for a year and a half, before I came to Woolwich, and before that I was in India.

13,459. Was there more typhoid fever before you came to Woolwich, do you know?—There was a considerable epidemic of typhoid fever before I came there, and I had to deal with one at Hanwell.

*Dr. T. Maxwell.*

23 May 1883.

Cross-examined by Mr. B. Morice.

13,460. Have you ever felt any illness yourself from this smell; I do not mean any serious illness, but any slight illness?—I cannot say that I have.

13,461. Have any of your patients had any illness of that kind without amounting to anything serious; nausea for example?—Many patients have, of course, nausea, which one cannot attribute to anything in particular, but I have never had occasion to attribute it to sewage in the river. I know I have heard patients attribute nausea and headache to the manufacturing smells that we get from the river.

The witness withdrew.

Mr. William Warman Coleman called in and examined.

13,462. (*Mr. N. Bazalgette.*) You are a member of the Royal College of Surgeons?—I am.

13,463. And you have lived for the last 26 years at No. 3, Plumstead Road, Woolwich?—Yes.

13,464. How far do you live from the river?—I live about 200 or 300 yards from the river.

13,465. First of all, will you tell us whether either you, or any member of your family, have experienced any ill effects by reason of your proximity to the river?—Not the slightest.

13,466. Have you been in practice in Woolwich during the whole 26 years?—I have.

13,467. I believe, for five or six years, you have been one of the doctors attending the Arsenal?—Yes.

13,468. And you are certifying surgeon for the district under the Factory and Workshops Act, 1878, are you not?—I am.

13,469. In the discharge of your duty, do you have constantly to visit factories and workshops?—Constantly.

13,470. In the course of your practice do you visit a great number of people who live upon the river bank?—Yes.

13,471. And you visit the families of working men?—I do.

13,472. Do you find zymotic diseases prevalent amongst your patients?—Certainly not.

13,473. Do you consider Woolwich a healthy town?—I should call it a particularly healthy town, considering the enormous population of Woolwich and Plumstead; it is all one place, in which the population is very large and the health very fair.

13,474. (*Sir John Coode.*) Do you know what is the average death rate over a period of seven years?—Unfortunately we have no statistics; though it is a very large town, and I daresay they have plenty of money, yet I think it is the only town in England where they have no medical officer.

13,475. (*Chairman.*) A part of Woolwich, I should suppose, is a naturally healthy place, it is high ground, and it is chalk and sand?—Yes, it is a nice gravel and sandy soil.

13,476. Could you discriminate between those higher parts and the lower parts in regard to the death rate?—Singularly enough, the greatest number of zymotic diseases have occurred across Plumstead Common, at a place called the Slades; they have the largest number of zymotic diseases at that part which is more remote from the river; whether due to defective drainage or not, I do not know. As a matter of fact, the lower part compares very favourably with the higher.

13,477. (*Mr. N. Bazalgette.*) Now I will ask you, with your experience, have you ever known a case of zymotic disease which has been produced by sewage in water, except where the mixture has been drunk?—I do not think I can call to mind one case that I have ever seen or heard of.

13,478. I believe you had eight cases of death amongst your patients in 1882?—Yes, I had.

13,479. Were any of those cases from zymotic disease or blood poisoning?—Not one.

13,480. Has the drainage of Plumstead Marshes had any effect upon cases of intermittent and typhoid fever in the parish?—A very great effect. Since the opening of the outfall sewer, many of these dykes have been drained, and now the marshes are very much more healthy than they used to be.

13,481. As you told the noble lord, you think that the cases of zymotic disease are, as it happens, more prevalent in the districts that are more remote from the river?—I cannot say that has always been the case, but I have noticed that recently.

13,482. Have you often seen the mudlarks playing about in the mud off Woolwich Arsenal?—Yes, I have.

13,483. Do you attend many of the poorer class of parents there?—Yes, I do; the boys are constantly bathing off the Arsenal the whole day long.

13,484. Have you ever had any cases of evil results arising from that?—Never, except from immersion and suspended animation when a boy has gone beyond his depth.

(*Chairman.*) He must have swallowed the mixture then, it would not be a case of the gas only.

13,485. (*Mr. N. Bazalgette.*) On the night of the

*Mr. W. W. Coleman.*

*Mr. W. W. Coleman.*

23 May 1883.

"Princess Alice" disaster what were you doing?—I was rowing about in a small boat, examining all the people who were picked up.

13,486. What were you doing the next day?—I was on board the "Heron" steamer, and we were picking up the bodies.

13,487. Were the bodies that were found put on board the "Heron" steamer before they were brought ashore?—Yes, they were.

13,488. Of course you saw them?—I did.

13,489. Did you see all the bodies that were brought on board the "Heron"?—I did.

13,490. Did you notice whether they were particularly muddy, or had the appearance of sewage about them?—No, not especially.

13,491. You have seen many cases of drowning, I presume?—Yes, I have.

13,492. Do you find as a rule that bodies which are taken out of the Thames are more or less always in a muddy condition?—Yes, always.

13,493. Did you ever notice any smell in the river?—Since I was first interviewed with regard to this matter, I have crossed the river by the ferry at low water to notice whether the paddles would stir up the mud particularly, and I have been surprised to see how little smell there really was.

13,494. Previously to your having paid special attention to that fact, had you ever noticed the smell from the river, passing it as a casual traveller?—No, never.

13,495. Have you noticed the smell from the factories in the neighbourhood?—Frightfully, at times.

13,496. Is that very bad?—Very bad, particularly at night, when the wind is in the east or the north-east.

Cross-examined by Mr. Balfour Browne.

13,497. You have said that since your attention has been directed to this inquiry you have noticed the smell, though you were surprised it was so little?—I was surprised to find so little smell, I expected to find more.

13,498. Why did you expect to find more?—I had heard so much of the offensive state of the river.

13,499. Did you hear that from your patients?—No, from reading the newspapers and hearing of what was going on.

13,500. Going on where?—At the examinations and in various places.

13,501. What papers were you first referring to when you said newspapers?—The daily papers, and I have seen boats floating by with people taking samples for an examination of the Thames water.

13,502. But you say you have seen accounts in papers speaking of examinations; what examinations were those; the reports are not published of this Commission?—They are not published verbatim, but you get sufficient hints of what is going on to have an idea, and when I was going to be examined with regard to this matter I took the trouble to go down to the riverside to see it myself.

13,503. Did you ever try whether the mud upon the banks of the river smelt offensively?—I have been down there sometimes and have not noticed it.

13,504. But you have been there sometimes and have noticed it, I suppose?—Very slightly indeed.

(*Chairman.*) This gentleman is giving his evidence in an excellent manner, and I would ask you, do you think you can make a good affirmative witness out of him?

13,505. (*Mr. B. Browne*). No, I do not think I can. (*To the witness.*) What diseases would you expect to find alongside of a river into which large quantities of sewage had been poured?—Typhoid fever and scarlet fever.

13,506. I thought you said zymotic diseases were never communicated from water, in your experience, unless the water were drunk?—Not from the water, but from the residue which remains upon the bank of the river.

13,507. If there be a deposit formed upon the bank of a river; that deposit might cause typhoid fever, and the typhoid fever might be communicated to other places, is that so?—It might be.

13,508. (*Sir J. Coode.*) How do you think it might be communicated?—You are aware that, when the sun plays upon a bank where you have noxious matter exposed, you have emanations given off which no doubt more or less poison the air.

13,509. Would you think that the germs of disease would be conveyed from that through the air?—It is a very doubtful point. I very much doubt whether the great physiologists agree upon that matter.

13,510. (*Mr. B. Browne.*) I am not asking, nor is Sir John Coode asking, what great physiologists would agree upon, but have you not found in your own practice that zymotic diseases have been conveyed by sewer gas?—Yes, undoubtedly by sewer gas.

13,511. Therefore the germs or the factors of the disease must be carried by means of the air?—Yes, undoubtedly.

13,512. Therefore, if noxious matter were deposited upon the bank or the shore, it would be carried by the air to the people along the banks?—I do not know that, because I have had one man living upon the bank who has resided there 19 years with his family, who has had no cases of that kind in his family.

13,513. But do you mean to say that one man is a criterion?—No, but there are other families which have no case of disease. This man I am now speaking of has resided at No. 1 Land Magazine, upon the marshes, 19 years, and has never had a case of disease in his family from that cause.

13,514. Have you compared the death-rate in the parishes by the banks of the river with the death-rate in the parishes not affected by the river?—I have not done so.

13,515. Have you ascertained whether diarrhœa, measles, and typhoid fever, are more frequent in the riverside parishes than in other parishes?—I have not gone into that.

13,516. (*Sir J. Coode.*) This is a very important point, and I am not quite sure whether I rightly understand Dr. Coleman's evidence; he meant that typhoid fever might be communicated by gas emanating from a sewer, but do you think the same would apply to emanations from river banks under a hot sun?—I do not know so much about that, that would be a moist vapour more than anything else.

13,517. You would be more sure about sewer gas than the gas from a deposit on the banks?—I should not like to give an opinion upon the last point.

13,518. That, as you say, is a moot point between the highest authorities?—Yes, I believe so.

13,519. (*Mr. B. Browne.*) Do you think that, because there would be a larger proportion of moisture in the atmosphere, that would render the germs innocuous?—No, I do not say that, but I think it would be more doubtful than in the case of sewer gas.

(*Chairman.*) The witness has come prepared to speak to matters within his own knowledge, and we shall have scientific witnesses who, as I understand, will come prepared with such evidence as you are now endeavouring to get from this gentleman, and he might very fairly say, Do not ask me about this, I have not studied this matter.

13,520. (*Mr. B. Browne.*) If he says he would not express an opinion, that would be a different thing. (*To the witness.*) Have you seen the Report of Messrs. Bidder, Hawkesley, and Bazalgette, upon this matter?—I have not.

13,521. In fact, you have not prepared yourself in any way to give evidence?—I have not. I did not

know I was coming up here as a witness till yesterday afternoon.

13,522. The conclusion those three gentlemen came to was, "The condition of the stagnant mud is injurious to health,"—you would not agree with that?—I would rather not answer that question.

*Mr. W. W. Coleman.*

23 May 1883.

Re-examined by Mr. MICHAEL.

13,523. A thing may be injurious to health, I suppose, without creating zymotic disease?—Undoubtedly.

13,524. Whether it is communicated by germs or by gas, is the condition the same of gas given off by sewage in a closed sewer, and of gas or vapour given off from the banks into the open air, where it is diffused in an immense bulk of air?—No doubt, there is that difference.

13,525. May there be something bad given off from mud without its being productive of zymotic disease, either typhoid fever, measles, or scarlet fever?—Undoubtedly.

13,526. As I understand, you do not want to give any opinion as to what is the special origin of zymotic disease?—I would rather not give an opinion upon a matter of that nature.

Examined by the COMMISSION.

13,527. (*Dr. F. de Chaumont.*) Have you been aware of any change in the general condition of the health of the district before and after the outfall?—I find a very remarkable change. Operations I had to perform many years ago were very frequently followed by intermittent fever; that was while the marshes were full of foul water, and the same thing was the case with regard to confinements.

13,528. Do you wish to make us understand that the general tone and health of the district has rather improved than otherwise since the opening of the outfalls?—I believe so, greatly.

13,529. There has been no deterioration since the establishment of the outfalls, at all events?—Not the slightest.

13,530. Did I understand you rightly as saying that there was no medical officer at Woolwich?—Not one.

13,531. (*Colonel Ewart.*) You stated that you had, since you were interviewed, more closely observed the river; when did that interview take place?—I dare say six weeks or two months ago, and that drew my attention to it more particularly in the first instance.

13,532. Your examination did not extend to the hot season of last year?—No, but six weeks ago my attention was drawn to the matter, and, thinking the question might arise, I went down to see some patients of mine who live upon the river bank, and I also went across the ferry at low water more frequently to see the effect when the water was stirred up by the paddles of a steamer.

13,533. And that was within the last two months?—Yes.

13,534. (*Dr. Stevenson.*) You spoke of the bodies taken out of the river after the "Princess Alice" disaster, and compared them with other bodies found in the river; from what other portions of the river were those others taken?—They were mostly the bodies of people who had fallen in from vessels, or from swimming and getting out of their depth.

13,535. But in the same locality?—Yes, mostly, just by the arsenal.

13,536. You have not observed the condition of bodies taken from other portions of the Thames?—I have not.

13,537. Do you know in what time decomposition set in in the bodies that were recovered after the "Princess Alice" went down?—From their all dying in good health and in full habit of body, decomposition would set in more readily than it would in ordinary cases of death, but moreover you will remember, that that was a warm September, and I think that had a great effect.

13,538. Were the bodies black?—No, the faces were all turgid and bloated, as is invariably the case in cases where animation is suspended suddenly.

13,539. It was given in evidence that the bodies were in a very offensive condition in two days, was that so according to your experience?—That would be so in the cases of many of the more obese people, as decomposition sets in so suddenly.

13,540. (*Chairman.*) Does your practice extend at all in the direction of Erith?—I go up the marshes frequently. I have been down there to see people who have removed in the direction of Erith from Plumstead, they having been my old patients.

The witness withdrew.

(*Mr. Chatterton's Level Books were handed in for examination.*)

Mr. F. LETT called in and examined.

13,541. (*Mr. Michael.*) You are a member of the Royal College of Surgeons of England, a licentiate of the Royal College of Physicians of Edinburgh, and a Licentiate of the Society of Apothecaries also?—Yes, I am.

*Mr. F. Lett.*

13,542. And you reside at 32, Rectory Place, Woolwich?—Yes.

13,543. How far is that from the river?—It is about a quarter of a mile from the river.

13,544. How long have you been there?—About 11 years.

13,545. You practise as physician and surgeon, I presume?—Yes.

13,546. And you are one of the district medical officers to the Woolwich Union?—Yes.

13,547. In what part of Woolwich do you practise?—Near the centre of the town, I think.

13,548. Does your district extend from the side of the river to Woolwich Common?—Yes, towards the top of Woolwich Common from the riverside.

13,549. Have you many patients among the labouring classes employed upon the river and residing near it?—Yes, residing near it, certainly, and upon it too.

13,550. Have you had any cases in your practice that you could trace to the presence of sewage in the river?—No, not distinctly traceable.

13,551. What is the general ratio of zymotic disease in your practice, as compared with the ordinary ratio of zymotic disease to other diseases in the country?—I consider it is low comparatively.

13,552. Have you cases of typhoid fever?—I have had some.

13,553. And diphtheria?—Yes.

13,554. And diarrhœa?—Yes.

13,555. Have you had any cases of scarlet fever?—I have.

13,556. And measles?—Yes.

13,557. With respect to all those diseases, have you ever had any case that could be traced to riverside occupations?—No, I have not.

13,558. Have you had occasion to look at the river with respect to its sanitary condition?—No, I do not know that I have been called in officially to do that, though I have had opportunities of judging.

13,559. But have you used your opportunities, have you considered in your practice whether or not the condition of the river had any effect upon the general

*Mr. F. Lett.*

23 May 1883.

health?—I have not been able to trace that it has had any deleterious effect upon the health of the inhabitants.

13,560. In your opinion, what is the general health of the inhabitants?—Very fairly good.

13,561. Have you been able to smell the sewage in the river in hot weather?—Yes.

13,562. Did you during the last year?—I am not sure that I did during the last year.

13,563. Have you formed any opinion as to whether the deposit, upon the banks of the river, of the mud has occasioned any disease?—I have not been able to trace any disease from it.

13,564. Whether zymotic disease or otherwise?—Whether zymotic disease or otherwise.

13,565. Do you think that sewage in water could create zymotic disease; I do not mean drains, but flowing along past the district?—Really, I would not like to answer that question.

13,566. Have you any smells from factories in your district?—Yes.

13,567. Are they offensive?—Certainly.

13,568. (*Chairman.*) Are they productive of disease?—I would not like to say that, but certainly they are very disagreeable, and smelling very strong indeed at times.

13,569. Just let me interpose this question: have you had this sort of thing happen to you, that your patients say to you, We seem to have been very poorly. There has been a good deal of diarrhœa and a tendency to nausea, so that people, without having a sufficiently specific complaint to come to a doctor for, would be uncomfortable. Do you have anything of that sort?—Nothing to call for any special remark upon my part.

13,570. When you say you have smelt the river yourself, has the sewage smell been to such an extent as to be merely unpleasant to those who have to smell it, or injurious to their well-being?—It would be very unpleasant, and, in the hypothetical case of people being already in ill-health, it might be to a certain extent injurious, or of a prejudicial character; but I could not give any specific instances within my own knowledge.

13,571. (*Mr. Michael.*) Upon the shore of the river or inland?—What I am now saying would, I think, apply to the river side.

13,572. Have you ever been able to divide your practice into two zones, the riverside zone and the inland zone, so as to enable you to say whether this is more unhealthy than that?—I have not been able to do that.

13,573. (*Sir John Coode.*) Have you ever thought of that before?—Not until lately, but I have had so much to do with it, that I should be able to remark it if such a thing had existed.

13,574. (*Mr. Michael.*) Would you have been able to record whether one zone was more remarkably unhealthy than the other?—Certainly.

13,575. With regard to the diseases supposed to be derived from bad air and bad water, have they been of such prevalence near the river as to draw your attention to them?—They have not.

Cross-examined by Mr. Lumley Smith.

13,576. Have you in all cases been able to trace these diseases of typhoid fever, diarrhœa, and measles, to the river?—No.

13,577. Have you been able to trace them to any cause, or has the origin of them been left untraced in most cases?—It has remained untraced in most cases.

13,578. With regard to the class of people who live nearer the river, are they of a poorer class than those who live further back?—They are of a poorer class, no doubt.

13,579. And for that reason, being poorer, they would be less likely to call in medical attendance?—I am medical officer of the Union, and they have medical attendance gratuitously.

13,580. But with regard to what the vicar of Plumstead described as being a diminution of the *vis vitæ*, they would not be likely to call in the assistance of the medical officer in such a case as that, would they?—But then, you see, the medical officer has the power to order other things besides medicine, which are very much desired by the poorer classes, such as aliment.

13,581. But clubs are not very liberal in these matters, are they?—But I am the medical officer for the Guardians, and I have the power to order many more things other than medicines.

13,582. (*Chairman.*) Your work is not piece-work; it is not your interest not to diminish your patients?—No, not at all.

13,583. You are paid a salary, I take it?—Certainly.

13,584. (*Mr. Lumley Smith.*) As regards such ailments as the vicar of Plumstead described, the people would be hardly likely to come to the district medical officer, would they?—I think they would in many cases.

13,585. Now, with regard to what you told us, that the effect of the river would be injurious to persons in ill-health?—I meant that anything of a disagreeable nature would more affect persons of a delicate constitution and weak persons than strong people; that was the sense in which I meant it would affect them.

13,586. (*Dr. Stevenson.*) Have you had an opportunity of comparing your district, medically speaking, with other districts; have you practised in any other part?—I have not practised in any other part, or very little.

13,587. Have you any reason to suppose that these sensations of nausea are more prevalent in your district than in others?—I am not aware of that.

13,588. Have you no reason to believe it?—It has not been brought before me.

13,589. You do not think such cases are more prevalent there than elsewhere?—It has not been brought before me, and I have no reason to think so.

The witness withdrew.

Dr. Alfred Rowarth called in and examined.

*Dr. A. Rowarth.*

13,590. (*Mr. N. Bazalgette.*) You are medical officer of the "Exmouth," are you not?—I am.

13,591. Where is the "Exmouth" stationed?—Off Grays.

13,592. Do you live at Grays?—Yes.

13,593. Do your duties constantly take you on board the "Exmouth"?—I go on board every day excepting Sunday.

13,594. Therefore every day you have opportunities of judging of the state of the river?—Yes.

13,595. Will you tell us first of all whether you have ever observed any traces of sewage in the river?—I never have.

13,596. Have you ever observed any smell from the water?—None.

13,597. How about the banks; have you ever observed any smell from the banks?—Not of sewage.

13,598. Have you observed anything beyond what you experience from mud banks as a general rule?—Not anything.

13,599. Do the boys of the "Exmouth" bathe in the river?—In the summer months.

13,600. And do they have a bath on board the ship which is filled from the water of the river?—Every morning.

13,601. Do you bathe yourself?—Occasionally.

13,602. I need hardly ask whether you would bathe in your own practice, if you thought there was sewage in the river at that point?—I do not think I should.

13,603. Have you ever seen anything perceptible in the state of the water which would lead you to suppose that sewage was discharged at a point higher up?—No, I have not.

13,604. What is the health of the "Exmouth" boys?—It is very good indeed.

13,605. Is fever or diarrhœa distinguished by its absence on board?—It is.

13,606. (*Sir John Coode.*) How long has the "Exmouth" been where she is now anchored?—I think about 11 or 12 years. I have been in connexion with the "Goliath" and "Exmouth" for the last 11 years.

13,607. (*Mr. N. Bazalgette.*) How many boys are there on board?—There are between 500 and 600.

Cross-examined by Mr. Balfour Browne.

13,608. At what age are the boys received on board the "Exmouth"?—Twelve is the youngest.

13,609. And at what age are they discharged from the "Exmouth"; how long do they remain?—Until they are 15, not over 15.

13,610. Those are peculiarly healthy ages, are they not?—But they are not healthy boys when they are admitted, they are just the contrary.

13,611. As I understand you, you row out to the ship every day?—Every day.

13,612. Do you mean to say that you never detect any smell of sewage in the river?—Never.

13,613. Not even in hot weather?—Never.

13,614. You say you have detected the smell from the mud, but not what you would expect from the sewage; what kind of smell was it?—An earthy kind of smell, not an unpleasant smell.

13,615. If it occurred in hot weather, does not that look as if it were due to some decaying matter rather than to earth?—It is not a disagreeable smell; there is a difference between what I should call a sewage smell and an earthy smell; I could detect the difference directly.

13,616. Now Purfleet is where the "Arethusa" is stationed, is it not?—No.

13,617. Where is the "Arethusa" stationed?—She is at Greenhithe.

13,618. Is not there one of the vessels opposite Purfleet?—Yes, the "Cornwall."

13,619. Do you know that they complain very much on board the "Cornwall" of the river, and of the smell of the mud?—I dare say they do; I should say it is very bad indeed on Board the "Cornwall" at Purfleet.

Cross-examined by Mr. Beaumont Morice.

13,620. Do you know whether it is bad at Greenhithe?—I do not know whether it is bad at Greenhithe.

13,621. Do you know that on board the "Arethusa" they complained?—No, I do not know that; my observations have been confined exclusively to Grays, except that now and then I have been to Purfleet and have seen that the river was not so clear at Purfleet as it was at Grays.

Examined by the Commission.

13,622. (*Chairman.*) How many miles are you above Gravesend?—I do not know exactly how many miles, but I should think from four to five.

13,623. Is Gravesend still a bathing place; it used to be a bathing place at one time?—There are baths there, but I do not think the people bathe in the river there now, because there is no convenience for it.

13,624. Have you noticed the water at Grays at low water?—Yes, at all times.

13,625. Is it even then sweet enough to bathe in?—I have bathed upon the lowest ebb tide.

13,626. Without any consciousness that you were bathing in foul water?—Yes, I should prefer to bathe at the top of the flood, of course.

13,627. It is salter of course then?—Yes, it is.

13,628. Is that your only reason?—It is clearer.

The witness withdrew.

(*Mr. Michael.*) I have exhausted my four witnesses, and I now propose to read the extracts from the papers relating to Erith. You know we agreed that the Report from Mr. Easton, and a variety of other reports in connexion with Erith, should be put in, and, as I mentioned to your Lordship at the commencement of our sitting, it would be necessary to direct the attention of the Commission to those matters which we have extracted from a very voluminous mass of papers—they are before you—it would take much longer than 20 minutes to read them, but if you like, I will commence reading them now.

(*Sir J. Coode.*) Is this the residuum?

(*Mr. Michael.*) Yes, and I propose to read these extracts. These are matters agreed with the Erith people; we have gone all over the papers belonging to Erith, and these are papers which we think are of importance, and we have mutually agreed that they should be laid before the Commission.

(*Chairman.*) Then I should say, the sooner we begin it, the better.

(*Mr. Michael.*) My learned friend Mr. Bagalzette will read them.

(*Mr. N. Bazalgette.*) The first is a Report by Mr. Edward Easton.

(*Chairman.*) I think we had better first understand exactly what the papers are.

(*Mr. Michael.*) Erith has appeared here specially to make a complaint against the Metropolitan Board of Works; a great deal of correspondence had taken place, and a great many matters had been discussed at Erith with respect to the getting rid of certain difficulties which they have experienced with respect to drainage and other matters; a great deal of that we thought it was unnecessary to bring before the Commission, or to trouble the Commission with, and therefore my learned friend Mr. Beaumont Morice, and myself went over the whole of the documents to see those things which I considered material, and that he might see that I did not make any undue selection, leaving out other matters which would in any way modify those things which I had selected. It was agreed that the documents so selected should be put in before the Commission, but I knew that if they were put in the Appendix they might entirely escape the notice of the Commission, and I therefore proposed that they should be read. I think, mainly, they may be divided into three heads; a gentleman called Easton, who will subsequently appear as an engineer on behalf of the Metropolitan Board of Works, was called in by the Erith Local Board for the purpose of advising them with respect to their drainage, and many of these documents are reports addressed by Mr. Easton to the Erith Local Board. Besides that,

22 May 1883.

there are some reports of the Surveyor, and there are also reports and letters addressed to the local board with respect to nuisances arising on the banks of the river, other than the nuisances complained of, with respect to the river itself. Those are the three heads under which the evidence may be divided.

(*Chairman.*) You put these letters as a sort of evidence against Erith, saying, as it were, Erith has done this, that, and the other, and we put this in against you.

(*Mr. Michael.*) It will modify the evidence which Erith has put in, and will explain what it is essential the Commission should know. I can put it generally in this way. Erith says, The whole of the complaint that we make is against the river. Now these documents show that these matters of which they complained arose from the drainage of Erith itself, and from other matters, and those are matters which arose upon the cross-examination of their witnesses, and which they agreed to put in. There are many documents which they offered to produce, and which they undertook to produce.

(*Chairman.*) I understand that the principle upon which these are put in is that Erith has said and done this, that, and the other, and it is proposed to put in this against Erith.

(*Mr. B. Morice.*) Yes, but if you will allow me to say so, my learned friend Mr. Bidder, or my learned friend Mr. Michael, in cross-examining, was anxious to know if there were not any complaints to the Erith Local Board of the factories in the neighbourhood. It was stated that there was correspondence with respect to the factories, and the Chairman, then Sir Benson Maxwell, asked if there would be any objection to putting in this correspondence. We stated we would be perfectly willing to put forward, for the purpose of my learned friend, any correspondence which had taken place with regard to the factories.

(*Mr. Michael.*) But that is a very small portion of it. We asked if it were not the fact that Erith had been endeavouring for years to remedy grave defects which had existed with respect to the drainage and the drinking water. Erith alleged that it had suffered, owing to the sewage poured in by the Metropolitan Board of Works, and we asked, Was it not the fact that your people have suffered from your own bad drainage, and your local arrangements, and did you not call in Mr. Easton? I ask permission now to read the first letter from Mr. Easton to their own local authority, which will put the Commission at once *au courant* as to the whole of these matters.

(*Chairman.*) I am doubtful about it, because the right thing to do would be to call Mr. Easton and ask if he proposed to do one thing or another.

(*Mr. Michael.*) I propose to call Mr. Easton by-and-bye.

(*Mr. B. Morice.*) My clients were anxious to withhold nothing from the Commission, but, on the contrary, to give them every information in their power, and that is what we do here.

(*Mr. Michael.*) You will remember that Mr. Jessett was examined, who was one of the local officers of health, and he was asked if he did not make reports upon the health of the place to the Local Board, and here we have the reports, not only of Mr. Easton, but of the Surveyor, and of Mr. Jessett, and of others.

(*Chairman.*) If that is agreed to, we must read these documents.

After an informal discussion, it was ordered that, in the first place, the documents be printed as an Appendix.

Adjourned to Tuesday next, at half past 12 o'clock.

---

# THIRTY-FIFTH DAY.

## Tuesday, 29th May 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

Mr. HENRY LAW, Memb. Inst., C.E., called in, examined by Mr. NORMAN BAZALGETTE.

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

13,629. You are a member of the Institution of Civil Engineers?—I am.

13,630. And a member of the Council of the Sanitary Institute of Great Britain, and a Fellow of the Meteorological Society?—Yes.

13,631. When did your acquaintance with the River Thames commence?—In 1837. I was then articled to Sir Isambard Brunel who was constructing the Thames Tunnel.

13,632. Did the nature of that work render it necessary that you should acquaint yourself with the movements of the tide and the conditions of the river bed?—Yes; it was so important to know what was going on in the river that we always had one of the engineers afloat to communicate with the engineer in charge of the tunnel below; we had signal poles for the day and lamps at night, so that if it were reported that water was coming in at a particular part of the shield the engineer was communicated with.

13,633. (*Chairman*) You had, in short, occasion to watch the tides?—Yes, I had occasion to watch the tides carefully, and to make daily observations upon the river.

13,634, (*Mr. Norman Bazalgette.*) Then upon the conclusion of the Thames Tunnel, I believe, you became chief assistant to the late Mr. Thomas Page?—I became chief assistant to the late Mr. Thomas Page, who was the chief acting engineer of the Thames Tunnel, and I made the working drawings under him for Westminster Bridge.

13,635. Was Mr. Page then employed in making drawings for the embankment of the Thames?—Yes, he was engaged in making drawings for the embankment of the Thames, and I, as chief assistant, was employed in making the plans for that work; the plans for the Thames Embankment must have been made in the years 1843 and 1844.

13,636. Did you, when those plans were being prepared, and in order to their being prepared, take a considerable number of soundings of the river?—Yes; soundings had been taken in 1796 by Capt. Shields, and in 1823, by Mr. Telford, extending from

Chelsea to Blackwall—it was 10 years before the removal of London Bridge—and in 1843 I took sections over the same lines for the purpose of comparing with the former soundings and seeing what change had been occasioned by the removal of London Bridge.

13,637. Can you tell me roughly how many sections you took between those points?—I cannot tell you the number at the moment, but I shall have occasion to produce them.

13,638. But I can put the figure to you; I have it that you took 61 sections?—Yes, I took quite that.

13,639. I believe that at the time you were with Mr. Page, all applications for leave to execute work upon the foreshore of the river had to be referred to Mr. Page, had they not?—Yes, proceedings had been taken in the Court of Chancery, in a matter between the Government Board of Works and the City of London, who were Conservators of the river, as to the ownership of the soil, and an interim order was made that before sanction for any works was given by the Conservators, a veto should be permitted to the Board of Works.

13,640. Did you when these applications came in, as Mr. Page's engineer, make the necessary local examinations?—Yes; I had occasion to visit all the spots, wherever they might be in the river, and to make the necessary examination.

13,641. I believe that in addition to preparing those plans for the embankment of the Thames, when you were with Mr. Page you also prepared plans for certain bridges across the River?—Yes, for the Chelsea Suspension Bridge, which was built by Mr. Page; for the Westminster Bridge, which was built by him, and for other bridges; one at Charing Cross, and one at Lambeth, where the present suspension bridge is; and I also had charge of two bridges which were built over the Thames at Windsor; the Victoria and Albert Bridges at Windsor were built under my direction.

13,642. Then I may take it generally that under this experience you acquired intimate knowledge of the Thames?—Yes, I did.

13,643. Have you read the whole of the evidence which has been given before the present Commission?—I have either read or heard it given.

13,644. Have you examined the whole of the plans and documents which have been put in?—Yes.

13,645. Now, I will ask you, first of all, what your view is with regard to the sufficiency and efficiency of the existing system of metropolitan drainage?—I heard the evidence which was given by Mr. Baldwin Latham, the general tenour of which was that the increase of London had outgrown the proportions of the drainage system, and that, in consequence, whenever any rain fell, it became inevitable that that rain would be discharged at one point or another by the storm overflows. I went very carefully into the matter to determine how far that was the case.

(*Chairman.*) I should very much like to know, as Mr. Baldwin Latham is here, does he agree that that was the tenour of his evidence (*to Mr. Baldwin Latham*). Do you agree that that was the tenour of your evidence?

(*Mr. Baldwin Latham.*) That was not the only point.

13,646. As far as Mr. Law has gone, is it correct?

(*Mr. Baldwin Latham.*) That is one of the points, but it needs qualification, because I pointed out as well that another cause of insufficiency was that the western district had been brought into the metropolitan drainage area.

13,647. (*Mr. Norman Bazalgette to the witness.*) Mr. Baldwin Latham has admitted that that was his meaning as far as your remark goes; will you now continue?—This plan (*handing in diagram No. 22, Appendix N.*) shows by the heavy dotted line the district of the Metropolitan Board of Works—the coloured portions are those which are drained; it will be seen that some portions of the district of the Metropolitan Board of Works are left white and are not drained.

13,648. (*Chairman.*) That is upon the south side, is it not?—Yes, both upon the south and upon the north, Hackney Brook, North Woolwich, figure 79, and a considerable area in the neighbourhood of Eltham. The district coloured red is that drained by he High Level sewer. The district coloured green is that drained on the north side by the Middle Level sewer; and on the south side by the Outfall Sewer; and the district coloured blue is that drained by the Low Level sewer. In order to ascertain precisely the work which each of those sewers, the High, the Middle, and the Low Level sewers, has to perform I have divided the several districts, which are each distinguished by separate numbers, according as they are drained into one or the other system. I have divided the population accordingly. I may as well give the whole population. Mr. Baldwin Latham, in his evidence, took the population of registration London as being more or less identical with that of what I may term drained London. Registration London, at the time of the census in 1881, contained 3,814,571 persons. I have, in a table, the number upon the North and South side, which I need not give separately, whereas Metropolitan London, which is not quite the same, contained 3,832,441.

13,649. (*Sir John Coode.*) Is what you call Metropolitan London that part within the black dotted line?—Yes; there are about 20,000 more persons in the district of the Metropolitan Board of Works than in the Registrar-General's District.

13,650. (*Chairman.*) We need hardly trouble ourselves with such a small fraction as that, need we?—No, but then I am going on to the district drained which contains 3,880,102. That I have divided into the portions coloured red upon the north, being those drained by the High Level, which contains 256,329, that drained by the Middle Level sewer containing 1,209,081, and that drained by the Low Level sewer containing 1,130,644 persons, The figures upon the south side I also have here, and, as I propose to put the table in, I do not know that I need read them, because I am dealing in these observations with the northern side, as that was the side which Mr. Baldwin Latham alleged during one year had really only discharged the sewage and allowed the whole of the rainfall to go into the river.

*Table No. 1 was handed in, and was as follows:—*

POPULATION of the METROPOLIS in 1881.

| | North of the Thames. | South of the Thames. | Total. |
|---|---|---|---|
| Registration London - - | 2,548,993 | 1,265,578 | 3,814,571 |
| Metropolitan London - - | 2,548,993 | 1,283,448 | 3,832,441 |
| Drained London - - - | 2,596,054 | 1,284,048 | 3,880,102 |

| | |
|---|---|
| *On the North side of the Thames:* | |
| Draining into the High Level Sewer - - - | 256,329 |
| " " Middle Level Sewers - - - | 1,209,081 |
| " " Low Level Sewer - - - | 1,130,644 |
| | 2,596,054 |
| *On the South side of the Thames:* | |
| Draining into the High Level Sewers - - - | 331,851 |
| " " Low Level Sewers - - - | 857,785 |
| " " Outfall Sewer - - - - | 94,412 |
| | 1,284,048 |

*Note.*—The population of North Woolwich is included in the numbers for the South side of the Thames.

I have here another table which I need not read, but the table contains, first, the numbers of reference to the plans; it is then divided into three columns, which give the population draining into the Middle, the High, and the Low Level sewers respectively for each of the districts, and therefore affords data for arriving at the quantity of sewage. Table No. 3 contains the same for the south side.

*Tables No. 2 and 3 were handed in, and were as follows:—*

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

POPULATION of the DISTRICTS drained on the NORTH SIDE of the THAMES in 1881.

| District. | Population draining into | | | Total Population in 1881. |

13,651. (*Chairman.*) Would you give us your results upon your own authority. Of course you can be cross-examined if the other side does not agree with you?—I am giving you the results, but I am only now going through these to show the principle upon which these tables have been calculated. The importance of the point is this: owing to the largeness of the district, the sewage from these different districts arrives at the terminus at Barking at very different times, and you will see, by the diagram which I shall put before you, that it is that which really answers the question.

(*Chairman.*) You had better do it your own way. I never found that I could save any time by endeavouring to cut matters short, but I do not mind telling you that, as far as I am concerned, there really, to my mind, has not been a substantial complaint established of the condition of the water above Greenwich. I do not mean to say that sewage has not been traced to be there, but what then? It is not a grievance of which anybody has made a loud complaint, or a complaint which you would be justified in going to an expenditure of millions to remedy.

(*Witness.*) Adding to that, that no plan you could adopt would prevent the necessity of having recourse to overflows at times.

13,652. (*Chairman.*) I suppose, if you trebled the sewers at a cost of about ten or it might be twenty millions of money, they would run over much less frequently than they do now?—No doubt, but it would be practically impossible to make those gigantic sewers.

(*Chairman.*) What has struck me is that there has been really no substantial complaint as to the condition of the river above Greenwich; there is no one who comes forward and says that there is.

(*Witness.*) No; but, as the evidence stands upon the notes now, it might lead you to believe that an essential part of any outlay would be for such a material alteration of the sewers within the metropolis as would prevent the overflows overflowing so frequently.

(*Mr. Norman Bazalgette.*) The way it stands now against the Metropolitan Board is that the discharge of the storm overflows above Greenwich has contributed to the fouling of the river below Greenwich.

(*Chairman.*) So it has, theoretically; no one can say anything more; but it would be a wonderful thing if it should be innocuous between Hammersmith and Greenwich, and should suddenly break out in a noxious form below. But still it is impossible for us to refuse to receive such evidence as you are now tendering, because we must consider the case upon all the evidence; and it may be that the learned counsel—for the prosecution I was going to say,—or my learned brethren, might consider that there was a grievance; so we must hear it.

(*Witness.*) The result, therefore, of this Table No. 4 is to show the amount of sewage which is afforded in 24 hours by each of the districts coloured upon the plan; and I show in the last column the intervals of time which elapse between the sewage from each of those districts entering the sewer and the time it arrives at the outfall at Barking. In order to determine the hour at which the maximum flow from each branch sewer will come down into the intercepting sewer, by which I mean the Board's Sewer, I have adopted the gaugings which were taken by Mr. John Taylor for the Referees to whom the Metropolitan Drainage Scheme was referred by the First Commissioner of Works previous to the construction of those works; because those experiments extended over some three or four months, and were taken with very great exactness. In this Report on Metropolitan Drainage of 1857, which I believe is in the hands of the Commission, will be found extremely elaborate tables taken every hour, and in some cases every quarter of an hour, giving the flow of the sewers; and a table is also given of the dry-weather flow. From that table I have prepared a diagram, which is now in your Lordship's hands, and you will see that the hours are beneath; that the sewage is at the minimum at 4 o'clock in the morning; then it rises up to its maximum at 10 in the morning; then it falls until 3 o'clock and rises again in the afternoon, and falls down towards midnight. That has been the basis that I have taken for the discharge of the sewage from the branch sewers into the Board's main intercepting sewer (*handing in a diagram*, No. 23, Appendix AO). I have then been able to arrive at the amount of sewage that would actually be discharged at each hour at Barking, which is of course the result we want to obtain, and it is an important question.

13,653. (*Chairman.*) This diagram is taken from the figures of 1857, but are the same sewers in existence now?—Yes; that represents a branch sewer, and the behaviour of the branch sewers is very much the same now as it was then. In Diagram No. 24, Appendix AP, the vertical height between the line AA and the line BB is equal to the total discharging capacity of the outfall sewer at Barking, viz., 34,764 cubic feet per minute. The portion of the diagram coloured red shows at each hour how much of that discharging capacity would really be occupied in carrying away the sewage at that particular hour; and therefore your Lordship will see that the maximum flow in the outfall sewer upon the northern side is at half-past two, when it amounts to about 15,000 cubic feet per minute. Diagram No. 33 Appendix AQ, gives a section of the High, Low, and Middle Level Sewers upon the northern side, and shows the height to which those respective sewers would be filled by the maximum flow of the sewage at the present time, that is to say, the dry-weather flow. Your Lordship will therefore see that in the High Level Sewer, which from the plan, you see, serves an area which is only partially built over, a very large provision has been made for future increase and for rainfall. The maximum flow in the High Level Sewer takes place at half-past one; the maximum flow in the Middle Level Sewer takes place at half-past two, and amounts to 7,788 cubic feet per minute; whereas the total discharging capacity is 16,620 cubic feet; and of the Low Level Sewer the maximum discharge takes place at 4.30, the discharge then being 6,570 cubic feet per minute, whereas the total discharging capacity is 14,524 cubic feet.

13,654. Do you take the end of the sewer to be the point of discharge?—Yes; the lowest point above their being united into the three sewers below; the three sewers below represent the three outfall sewers which carry the sewage from Abbey Mills to Barking Reservoir.

13,655. Are they the same size all the way through?—The outfall sewers are; the other sewers are graduated, commencing at from three to four feet in diameter, being graduated according to the work they will ultimately have to do, by which a great saving of expense was effected. Your Lordship will see the combined sewage of the three sewers fills the outfall sewer to a height of four feet, and leaves the carrying capacity shown upon the section No. 24 by the blank space above the red colour. So far with regard to sewage. Now I come to the rainfall. I have prepared a plan, No. 22, which shows also the proportion of each district, the rainfall of which has to be carried off by the sewers respectively.

13,656. Putting it very shortly, is what you say this: that the capacity, leaving out rainfall, is double the quantity they are now called upon to discharge at their maximum amount of flow?—Very much more.

13,657. I know that the High Level Sewer is very much more?—And the others also.

13,658. In dry weather, I am saying?—The High Level nine times, the Middle Level more than twice, the Low Level more than twice, the outfall sewers much more than twice. Now, with regard to rainfall. In the

*Mr. H. Law. M. Inst. C.E.*

29 May 1883.

same way I have a table, No. 5, showing Registration London, Metropolitan London, and Drained London, and I need only trouble your Lordship with these figures. Registration London contains 78,080 acres, of that number 3,361 acres consist of the River Thames or canals or other water, which, of course, must be excluded. Metropolitan London, without the water, contains 74,547 acres, but Drained London (without the water, of course) contains 65,001 acres, of which 32,158 are upon the northern side of the Thames and 32,843 upon the southern side.

*Table No. 5 was handed in, and was as follows :—*

AREA OF THE METROPOLIS.

| Total Drained London - | | 65,001 |

65,001 acres, equal to 101·56 square miles.

Here I might just incidentally mention that we have an explanation of the difference in the quantity of sewage per person upon the two sides of the river, because, while we have a very much larger population upon the northern side than we have upon the southern side, on the southern side we have to provide for an equal area of general drainage, such as the rainfall from the roofs of houses and the leakage from house drains, and imperfectly formed drains entirely beyond the control of the Board of Works, which are really inevitable and cannot be excluded. I may say the total acreage drained is 65,000 acres, which is equal to 101·56 square miles ; that is really the area in square miles which is drained. In order to arrive at the hours in which the rainfall will arrive at Barking, I have divided the areas amongst the several sewers precisely upon the same principle as I did the people ; and, in order to determine how much of the rainfall would be delivered into the sewers, I have made this assumption, which is really going upon the same lines as were suggested by the Referees in their Report of 1857. I have made this assumption, that wherever the population exceeded 80 persons to the acre,—and in some of the districts, as shown in the table, there are 300 persons to the acre,—but wherever the population was in excess or reached 80, I have taken the whole of the rainfall as going into the sewer. I have made the quantity of rain falling and actually reaching the sewers proportionate to the population, so that, if there were 40 persons to the acre, half the rain would go into the sewers ; and that is a very rational mode of doing it, because the density of population expresses very nearly the comparative proportion occupied by gardens and by houses, and for other purposes.

13,659. What you mean is that, if it is a sparse population, it falls upon the ground and gets absorbed; that is your supposition ?—That is so.

*Tables 6 and 7 were handed in, and were as follows :—*

AREAS of the DISTRICTS DRAINED on the NORTH SIDE of the THAMES, showing also the DENSITY of POPULATION and the RAINFALL discharged.

13,660. If it is a dense population, it falls either upon roofs or upon the paved streets?—That is so, and it finds its way to the sewers.

13,661. That is your proposition?—That is so, and that enables me to determine the quantity. Then, to enable me to determine the time, I have assumed that, if rain falls at any given spot, for instance, at Hampstead, the time which it would take to traverse the local sewers before it reaches the great sewer would be 180 feet to a minute, which is, I think, a fair and proper velocity to give. The diagram I have placed before you contains figures showing the hours the sewage will occupy in traversing the sewer before it reaches Barking, assuming the sewer to be running half full. I have desired really to make an investigation which should not be open to any question; and, therefore, I have taken the velocity as that due to the sewer when either half or quite full; whereas, under ordinary circumstances, the sewers are not nearly half filled, and the velocities are consequently not so great; but I wish it to be taken upon such principles as I think cannot be questioned. The result of the calculations so based is shown upon diagram No. 25 (*handing in the same, see Appendix* A k). I have assumed in this diagram that the rain commences to fall at the same time all over London, and falls at the rate of a quarter of an inch every 24 hours continuously without cessation for any period which you please. It will be then 2 hours and 20 minutes before the first rain reaches Barking, as shown by this diagram, because the outfall sewers are not sewers of reception, but merely of conveyance; they receive nothing after Abbey Mills; therefore, the first rain which falls, which will be that of the district of Bow, will take 2 hours and 20 minutes, or thereabouts, before it reaches the outfall, and this diagram shows you the successive increments of rain in the sewer until it has attained its full quantity, which would be delivered for ever if the rain continued at that rate.

13,662. (*Sir John Coode.*) This diagram reads from right to left, does it not?—Yes, it shows the intervals of time; the figures at the bottom are intervals of time before any given quantity will arrive. If we take the figure 6 and apply to it a scale, we shall see that it there measures about 10,500, and that means that it will be six hours after the rain has commenced to fall before the quantity being discharged at Barking will have amounted to 10,500 cubic feet per minute.

13,663. (*Mr. Beaumont Morice.*) You begin at the 2 hours and 30 minutes; that is the time before the first rain reaches Barking?—That is so.

13,664. (*Sir John Coode.*) The 0 is at Abbey Mills?—Yes, the 0 is at Abbey Mills.

13,665. And the rain entering at Abbey Mills takes 2½ hours to flow from Abbey Mills to Barking?—That is so. Now, if you apply the maximum rainfall to the maximum of sewage, you will still see a discharging capacity of 6,000 cubic feet per minute left in the sewer; so that is a very different state of things to that alleged by Mr. Latham.

13,666. (*Chairman.*) But I do not see that at present?—Applying the height of the blue to the height of the red, you can see how far it exhausts the discharging capacity.

13,667. Is that what you mean it for?—It is what I mean. I have made two separate diagrams in order that you may superpose the red at any part you like.

13,668. Suppose it rains for a week with a steady rain at the rate of a quarter of an inch per diem?—Then the quantity of rain coming off the ground would amount to 14,000 cubic feet per minute.

13,669. But I do not understand the use of the hour in the diagram, because, if it continues, I will put it for a week, as an extreme case, then you would have an equable flow all the way along, would you not?—You would have an equable flow all the way along, and what you would have to do would be this: having taken the height by your compasses, to see how much of your sewer would be occupied at any hour of any day, you would merely have to apply it upon the top of the red, and you would then see that, even when the maximum of sewage was flowing, your sewer would be only discharging that amount.

13,670. It would be more plain to an uneducated mind like mine if you put it in this way; how much of the sewer would that rain occupy, supposing there were no sewage flowing at all?—The rainfall alone without any sewage would occupy the proportion of the sewer shown upon the extreme left hand of the diagram No. 25, there would then be a parallel line all the way along. When the rain became continuous the line would become a uniform line, that will be the quantity of rainfall which came off the ground.

13,671. (*Sir John Coode.*) Assuming that it is not

an excess of a quarter of an inch in 24 hours?—Yes.

13,672. (*Professor Williamson.*) But is that in accordance with the fact; does it not sometimes rain in more than that proportion to the hour?—It certainly does, but I am coming to that point directly. What I have done is this, I have taken a quarter of an inch, because that is what the system is designed to carry, as Sir Joseph has told you. Therefore I want to show that the system is capable of doing that, and that a margin is left for an increase of population and of sewage.

13,673. (*Chairman.*) I think I understand generally what you mean, but still I think your diagram is a little too ingenious for me. What I understand you to say is that the sewer would carry off a continuous rainfall for a week of a quarter of an inch per diem, together with the maximum amount of sewage at any time?—Yes, that is so.

13,674. (*Professor Williamson.*) If it rained uniformly for 24 hours, but not otherwise?—That I am coming to; you have a surplus discharging capacity of between 5,000 and 6,000 cubic feet a minute.

13,675. (*Chairman.*) I do not quite see what the use of this blue diagram is, I understand perfectly how you apply it?—The use of this diagram, my Lord, is this. I think it is really necessary that I should now refer you to an answer.

13,676. I remember very well what Sir Joseph Bazalgette said, if that is what you are thinking of. Sir Joseph Bazalgette told us that he thought when he was designing the sewers, unless I am doing him an injustice, that when the sewage began to run there would be some time of the day at which it would be at its maximum, that it would be at its maximum at one spot, but that he found out that, in consequence of some of the supplies of sewage being nearer to the outfall than the rest, the distribution of the flow was more even than he had expected to find that it would be?—That is what the pink diagram shows. It is very remarkable how uniform the flow is until nine at night, but of course that arises from the fact that the sewage which comes from Chiswick takes nine and a half hours to reach the outfall, whereas that which comes from Bow only takes two and a half hours. But Mr. Baldwin Latham stated in his evidence that whenever it rained the storm overflows came into action at some part or other of the river. It was a most important statement, and one which it was only right fully to investigate, because, if it were so, some remedy would be absolutely necessary.

13,677. Mr. Baldwin Latham could not have said that whenever it rained in any quantity, no matter how small the quantity, the storm overflows came into operation?—It is so stated, it is upon the notes.

(*Chairman.*) I may put it hypothetically. If Mr. Baldwin Latham did say that, I should not believe Mr. Baldwin Latham.

(*Mr. Baldwin Latham.*) I should not have expected you to believe me.

(*Witness.*) It is upon the notes.

13,678. (*Sir John Coode.*) It must have been a misapprehension, or else explained elsewhere?—I am very glad that that is removed. I may further call your attention to this fact, that I have gone a little carefully into this matter of rain, because you have also a report which Dr. Frankland put in, in which Dr. Frankland assumes that of the whole quantity of rain which falls upon the whole of London, including the River Thames and the canals, however slight the shower, four-fifths falls into the sewers, and upon that very elaborate tables have been put in to show the quantity of detritus which is brought by the sewer and delivered and discharged into the Thames, so that it is a very important question.

13,679. (*Professor Williamson.*) Does Dr. Frankland say that there is always that proportion, or that that is the average proportion?—He says in this table, "The rain is calculated as falling upon 122 square "miles," the absolute area is only 102 square miles, and that of course contains an enormous quantity of vacant land, parks and squares, and places from which the rain cannot find its way to the sewers. "And "20 per cent. is allowed for evaporation, which is "probably much in excess of the truth;" he assumes that the whole of the rest falls into the sewers.

13,680. That must be the average?—No, each case. For instance, when only two-tenths of an inch fall, he has multiplied out the quantity of detritus (from what I think were imperfect data) which were supposed to be in the sewage with that quantity of rain, and has taken that as being discharged from the sewer into the river at Barking.

13,681. (*Chairman.*) I wonder whether Dr. Frankland ever knew this, I happen to have two cottages in the country, one covered with tiles and one covered with slates, and there are rain water tanks to both cottages, and the slate man, if he has the least shower of rain, gets rain in his tanks, but the tile man does not get a drop?—That is so. If you see a summer shower fall, it wets the pavement, but does not go into the sewer.

13,682. (*Sir John Coode.*) Was there no qualification in Dr. Frankland's statement?—So far from there being a qualification, he has reduced it to numerical results, and tables were put in to show them.

13,683. Under all conditions?—Under all conditions, however small the rain, and I shall of course have occasion to deal with that when I come to the discharge of the mud into the river, which is a very important point.

13,684. We shall hear your evidence, and shall see how that bears upon the table. I confess it did not strike me so.

13,685. (*Chairman.*) Have we no direct evidence from observation of the number of times the storm overflows have been seen to be in action?—Yes. Sir Joseph Bazalgette has given that to you, but you must bear this in mind, those observations could only be made at those stations where, from there being pumping or other operations going on, the Board have men to observe. Now at Question 7828 Mr. Baldwin Latham is asked, "Taking that district, how often "would the sewers be incapable upon the South "side?" To which he replied, "Upon the average "every time rain occurred the sewers must overflow "in the case of London."

13,686. I do not understand that "upon the average "every time"?—That is his answer. Then he is asked, "whenever it rained," to which he replied, "whenever it rained, at some point or other they "must overflow." I felt it desirable that that should be cleared up one way or another; it is very explicitly stated in the evidence. Now I wish to address myself to Professor Williamson's suggestion, which is a very important one, that of course this calculation of mine would be disturbed by a violent shower of rain; but this must be borne in mind. My diagram, No. 33, which shows the section of the sewers, shows how large an area remains unoccupied to be filled up by rain. The High Level Sewer, when the maximum flow of sewage is taking place, is only a seventh filled, and the vacant space which would be left available for rain would be 1,362,350 cubic feet before that sewer would become sufficiently filled to overflow by the storm overflows. The Middle Level Sewer would in the same way be capable of receiving with its maximum flow of sewage 1,115,290 cubic feet of rainfall before its overflows would come into operation, and the Low Level Sewer 1,675,623 cubic feet.

13,687. You mean for its whole length?—Yes, and the three outfall sewers, in the same way, 2,715,180 cubic feet, giving a total of 6,868,443 cubic feet, which is equal to eight hours' rainfall.

13,688. I do not quite understand you. You say the united capacity of the three main sewers and of the outfall sewers is so and so, what has that got to do with the storm overflows, because there is nothing overflows from the outfall sewer?—No, that is quite true, but that does not affect the question of the storm overflows; but the capacity of the three sewers, the

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

high, the middle, and the low level, must be filled before the storm overflows operate.

13,689. Do you mean there would be a sort of penning back?—Yes. If you recollect, Mr. Baldwin Latham stated that the joint discharging capacity of the three sewers was considerably in excess of that of the outfall sewer, which he said was a blot upon the plan.

13,690. Is it so?—No; this is the principle upon which they were proportioned. If you were to lay down for a moment the principle that each sewer should be capable of receiving all that the sewers coming into it would discharge, the principle being that the outfall sewer should carry all the three could bring down; then, if we come a little way further, and say the intercepting sewer must discharge all the branches can bring down; we should then be landed in this absurdity. There are 490,000 houses in London, each with a drain. Assuming each of those drains were only six inches diameter, and would discharge 40 cubic feet a minute, we should require, if the sewers in London were all discharging their maximum at once, 19,600,000 cubic feet, and we should require 1,680 sewers of that size to take away the sewage of London, instead of three.

13,691. The three intercepting sewers would not all be discharging at the same time?—That is so. The High Level having its greatest discharge at half past one, the Middle Level at half past two, and the Low Level at half past four, therefore the greatest economy was effected in proportioning the sewers to what they have to do. Before those sewers, the High, the Middle, and Low Level sewers, are united in the outfall, a storm overflow is provided in the River Lea, and similar storm overflows are provided, as indicated by Sir Joseph Bazalgette upon the plan, because it would have been practically impossible to have so designed the sewers as that they should have been competent to deal with the whole of the rainfall, which might under extraordinary circumstances have been delivered into them; but that is a very different thing from saying that whenever rain falls the storm overflows come into play.

13,692. As a matter of *a priori* calculation, have you come to any conclusion as to the number of times your storm overflows should come into operation?—I have not made that calculation; but the result of my calculation bears out the reasonableness of the return which has been furnished from observation. I would, in addition, say this, that these figures I have given you of the capacity of the sewers to be filled up by sudden falls of rain simply apply to the intercepting sewers themselves. I have calculated the capacity of the sewers of London, of which I have the dimensions; that would add two millions, and the sewers of the metropolitan district would be at least as much more, so that a very large number of hours would elapse before an overflow occurred, even after sudden rain. Now I have here an extract from a report which Mr. John Taylor made to the Referees as the result of his observations of the gaugings during heavy storms of rain. He says: "During the first four weeks of "the series of sewer gaugings, there was a "remarkable absence of rain, and, with the ex- "ception of the falls accompanying the storms "of June, there has scarcely been a sufficiently "decisive rain throughout the whole time to give any "very well defined results. An attentive considera- "tion, however, of the rainfall, with reference to the "gauging, evidently shows that no definite quantity "can be pronounced to flow off any given district, "with a given fall, so much depending on the "previous state of the ground, whether dried up or "saturated, on the season and amount of evapora- "tion, on the quantity of rain falling in a given time, "and on the long or short duration of the fall. In a "town district, such as that drained by the Savoy "and Northumberland Street sewers, it appears the "quantity running off into the sewers within six "hours after the fall of rain, varies from 10 to 60 per "cent. of the quantities fallen; while in a suburban "locality, such as the Counter's Creek sewer drains, "the quantity reaching the sewers would vary from "0 to 30 or 40 per cent. in 24 hours after the rain, "according to the previous conditions of the surfaces, "as above described, the remainder being carried off "by evaporation, absorption, and other causes." Then there is a footnote which is very valuable. "Of the "rain during the storm on the 20th June (nearly one "inch in 1¼ hour) 65 per cent. ran off this district "within 15 hours of the fall." It took 15 hours for the 65 per cent. to run off; 46 per cent. ran off in three-quarters of an hour after the rain ceased; 14 per cent. more in the next six and three-quarter hours, and 5 per cent. more in the next seven and a half hours, making the total of 65 per cent. Now I may mention that in the calculation I have made I admit of 70 per cent. running off. I am sure the calculation I have made is in excess of that which really happens. The result therefore is this, that, while the discharging capacity of the sewer is 34,764 cubic feet per minute, the maximum of the sewage will be 15,070, and the rainfall 14,242, leaving a surplus of 5,452 as the carrying capacity of the sewers, with the maximum sewage and rainfall.

13,693. (*Mr. Norman Bazalgette.*) That is to say, the margin which would be available for increase of population?—Yes. Now, I would wish to call your attention to Plan No. 22; you will see that certain districts are hatched round.

13,694. (*Sir John Coode.*) Are those discharging capacities which you have given to us the discharging capacities of the sewers when they reach the lip of the storm overflow; or do you assume the sewers to be absolutely full?—When they reach the lip of the storm overflow.

13,695. That will be their carrying capacity before the storm overflows have come into action?—Precisely so. Your Lordship will observe a certain district in the centre of London has hatched lines round it; that is the portion of London in which the population is now decreasing, and has been decreasing for several years. Out of the 80 districts into which I have divided London, you have 29 of those districts which have been for the last two censuses diminishing in their population and diminishing to this extent.

13,696. Each number represents a separate district?—Yes.

13,697. Does that apply to each of the 29 districts?—It is so. The figures are in the tables I have put in. In every one of those districts the population is diminishing; it contains 8,068 acres, or nearly one-ninth of the whole of the area under the Metropolitan Board of Works.

13,698. And what is the per-centage of diminution, taking it over the whole 29 districts?—In the city of London it is about a third of what it was 20 years ago.

13,699. But taking it over the whole of this hatched district?—I cannot give it at this moment but it is easily taken. Then I may mention that the adjoining districts show what has been called a decremental rate of increase, that is to say, that, although they increased very rapidly many years ago, that rate of increase as they attain their maximum is now becoming very slight, and after a few years they will have to be included in the shaded or hatched districts.

13,700. (*Professor Williamson.*) When you speak of diminution of population, you mean diminution in the number of people who sleep in the district?—Certainly. Then I would also point out another fact, which is this, that the future increase of London will be around its margin; it is diminishing in the centre; its population is spreading, consequently, the additional sewage which has to be brought in will be brought in at hours when the existing sewage is not running at its maximum; and that, again, makes a very important point when you are considering the size which should be given to the sewers. The principles upon which you would lay out the drainage for

a city of 117 square miles are very different indeed from those for a country town.

13,701. (*Chairman.*) If I cross Westminster Bridge, as I understand, I get into a district which you have marked as No. 58 ?—Yes.

13,702. Do you say the population is diminishing there ?—I say the population of Lambeth is diminishing, and I will give your Lordship the figures. I will put in the populations of all those districts; it will be a simple table.

13,703. Never mind that, unless they cross-examine you as to it. I will take it to be true. What inference do you draw from that ?—The inference I draw from that is that the population of London is spreading; that people now, who formerly lived in London, are enabled by the railways to live a little way out of London, so that the resident population of the denser portions is becoming less.

13,704. And what then ?

(*Professor Williamson.*) As regards sewage; that is the point ?—As regards sewage, of course the sewage round the margin of London is increased.

13,705. But does it diminish in the centre, that is the point ?—I have not referred to the day census of London, but I think the day census will be found pretty much the same.

13,706. (*Sir John Coode.*) Is there a day census ?—Yes, there is.

13,707. (*Chairman.*) How will all this affect our Report to Parliament with regard to the sewage of the metropolis ?—Very largely indeed, because, for instance, men do not take baths in the middle of the day, and the bath is one element and the largest element of the supply of water to the sewers.

13,708. (*Sir John Coode.*) What we want to arrive at is this: although the number sleeping within this particular district may be affected, how far is the sewage affected ?—I do not suggest, for a moment, a diminution of sewage, although I feel confident there is one.

13,709. You do not mean to convey to us that there is a diminution of sewage in anything like the ratio of population ?—No, but what I did mean was this: Mr. Baldwin Latham put in certain tables which assumed that the rate of increase of London was going on as it had done for some considerable time before, and I wish to show that not only is that ratio not going on so rapidly as it did, that it is what has been termed a decremental rate of increase; but I wish also to show that, as that increase takes place round the margin of London, that increase does not affect the sewer at the time when it is flowing at its maximum flow from the centre of London itself.

13,710. (*Chairman.*) There would be a more gradual flow from the sewers ?—Yes, the sewers would be filled at times when now they are not filled. I may mention also that, owing to some experiment now being made for a totally different purpose, one of the outfall sewers has been temporarily diverted from its use, the whole of the sewage being turned into the other two sewers, and that both the maximum time and the quantity of the sewage are singularly confirmatory of the conclusion which I have drawn here from these figures.

13,711. (*Sir John Coode.*) How long has it been that the two sewers are doing the work of three ?—The result is that they have been doing it with about 3 feet 9 of sewage in one and 4 feet of sewage in the other.

13,712. But how long have they been doing it ?—They have been doing it for about a month, and on Saturday, when it rained very heavily indeed, about 6 to 7 inches extra were gauged.

13,713. Was it gauged often on Saturday ?—It was not gauged, except by myself, for my own curiosity.

13,714. (*Chairman.*) Was the storm overflow at work ?—No, it could not have been, because the sewer was only running a little over 4 feet.

13,715. As I understand, if it rains very heavily at Chelsea, there might be an overflow at Chelsea, might there not, although the sewer were only half full ?—No, because you would have to fill up the Low Level Sewer.

13,716. Would you ? Because, as I understand, and that is certainly the case with the intercepting sewer, all the sewers are smaller the farther they are from the main outlet ?—They are, but proportionately to what they have to do at those places.

13,717. But what I said was, supposing a heavy shower at Chelsea, you might have at Chelsea an overflow, though, if there had been time for the water to get to the outfall, there would not have been an overflow ?—But, before an overflow can take place, you must have exhausted the carrying capacity of the sewers at Chelsea, and have filled up all the sewers; they would not begin to overflow until you had filled them; you must exhaust their carrying capacity, and also fill them; then they overflow, and not till then.

(*Sir John Coode.*) It would be what we call headed back.

13,718. (*Chairman.*) With great submission to you, I deny it. (*To the witness.*) Suppose you bored a hole in a tobacco pipe, and put some water in with very great pressure, the water would come out through that hole, though the bowl were not full, would it not ?—Yes, it might, but in this case the sewers are proportional to their work, and the water is not headed back; if it were headed back, the house drainage could not run into them.

(*Chairman.*) If I am wrong in this, let me be set right. Suppose the sewers at present in London to be of such a capacity that a shower of rain would fill them more quickly than they can discharge themselves, there would be an overflow there.

(*Sir John Coode.*) Yes, granting the premises, the conclusion is right.

(*Witness.*) Yes; but before you can do that, you have to fill the sewer up to the height at which the storm overflow is arranged to act, and, in doing that, you will have absorbed an enormous quantity of rain first to fill the sewer; and you will bear in mind that it is not stagnant water, but that it is flowing at very great speed, becoming greater as the sewer gets fuller.

13,719. (*Chairman.*) I know that, but I understand you to say that there could not be an overflow at Chelsea, because the outfall sewer was not full ?—If you so understand me, I did not express myself rightly.

13,720. (*Mr. Norman Bazalgette.*) Now, to go to another point. Will you tell us what your view is upon the question of the dilution of the sewage at the outfalls in the river ?—A very important part of this inquiry has been the percentage of sewage in the river, and I will address myself to that now; and, to avoid confusion of terms, I would say that we have to consider in the river the upland water, by which I understand the water which drains from the surface into the river, which finds its way by natural drainage into the river. Another kind of water which has not been spoken of, but is very important, is the spring water, which finds its way into the bed of the river through the springs; we have the sea water entering the Thames at the mouth; and the sewage; those four elements. Up to the present time you have heard nothing of the spring water; it has been quite ignored.

13,721. (*Sir John Coode.*) Can you show us cases of any perennial springs ?—Yes, I am now going to that question, and it is a very interesting one. I first of all wish to ascertain what it is reasonable that the river should deliver, comparing the upper and the lower. I therefore first ascertain the quantity of water which is abstracted by the water companies. I take the figures given by Mr. Baldwin Latham that the water supply was 16,090 cubic feet per minute, and I divide that according to the evidence given by Lieutenant-Colonel Bolton, who is the inspecting officer on behalf of the Local Government Board. The quantity abstracted from the Thames above Teddington Weir amounts to 7,778 cubic feet a minute, which must be added to the quantities gauged by Mr.

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

Baldwin Latham to ascertain what was the real discharge from the river; that is to say, what would have come over Teddington if the water companies had not abstracted it. In the same way, I add for the Lea 2,444 cubic feet per minute abstracted by the East London Waterworks, and I have also to add water taken by the New River Company from the underground springs at Amwell, amounting to 5,868 cubic feet per minute.

13,722. (*Chairman.*) What do you do with them?—You will see immediately.

13,723. At present all we are to take is that there is such a supply at Amwell?—5,868 cubic feet per minute are pumped up from springs in the Lea valley for the supply of London, principally into the New River; the New River, as your Lordship is aware, comes from that district. Taking Mr. Baldwin Latham's gaugings from the 7th September to the 30th November, during, in fact, the whole period, the mean discharge over Teddington Weir amounted to 338,488 cubic feet a minute, to which we must now add the 7,778 cubic feet per minute, and by that we find the quantity draining from the 3,676 square miles of country above that point was 346,266 cubic feet per minute, or 94·2 cubic feet per minute per square mile; that is the drainage of the Thames above.

13,724. That is to say, of the Thames basin?—Yes; the Thames basin above Teddington Weir.

13,725. Does that include the Amwell supply?—No, because that is in the valley of the Lea. Now, if we take Mr. Baldwin Latham's gaugings from the 7th of September, we find that the mean discharge below Teddington was 61,709 cubic feet a minute, to which we have to add the water abstracted by the Lea, and the water abstracted from the springs, which is 5,868 cubic feet; that makes for the 1,486 square miles below Teddington 70,021 cubic feet per minute, or 47 cubic feet per minute per mile, being only half below what is delivered above.

13,726. I have not the slightest notion what you are driving at?—Having given you the figures, I will explain what I have said, that, according to the figures which have been placed before your Lordship by Mr. Baldwin Latham, the quantity of water delivered from each square mile above Teddington is twice as much as that delivered from each square mile below.

13,727. It is said so?—It is so.

13,728. You say it is so?—I say it is so, and I will give your Lordship the figures; it is an arithmetical calculation, and now I am going to explain why it is so.

13,729. The quantity of water that runs off each square mile of the Thames basin above Teddington Weir is double that which runs off each square mile of the Thames basin below Teddington, is that your proposition?—Yes, as shown by Mr. Baldwin Latham's figures, and I am now going to give you an explanation.

13,730. (*Sir John Coode.*) That is what Mr. Baldwin Latham says?—That is what Mr. Baldwin Latham says, and I agree with him, and I will explain to you the reason why. Now Mr. Symons put in certain tables of rainfall.

13,731. (*Chairman.*) What it matters is what I should like to know?—Your Lordship will see that it is of the utmost relevancy, I can assure you. Now Mr. Symons, who is the highest authority upon rainfall, put in a map and certain tables upon which he gave the rainfall during the same period; that is to say, September, October, and November, in certain districts which he has numbered on that map which I have here. I have made a slight correction in the tables for this reason: Staines has been accidentally put by Mr. Symons in the lower river, whereas Staines, of course is in the upper river, it is above Teddington; that was done inadvertently, of course. In the same way, Crawley has been put in the upper, whereas it should be in the lower; and Salisbury, which is many miles from the district, and Andover and Cheltenham should not be included in the watershed of the Thames, whereas they are included by him, and I have excluded those places.

13,732. Cheltenham is in the Severn basin, is it not?—Yes, it is.

13,733. If I am not mistaken, there is a large stream at Salisbury called the Avon?—There is.

13,734. And which runs out at Christchurch?—That is so.

13,735. There is also a small stream at Cheltenham called the Chelt, which runs into the Severn?—It does so.

13,736. (*Sir John Coode.*) How does this correction affect the result?—Very slightly; but the result is, that the rain during the three months in the upper basin amounted to 13 inches, and in the lower to $11\frac{1}{4}$. Now, of course, to be fair in our estimate, to arrive at a reasonable result, we must discount these relative rainfalls.

13,737. Why should you discount them if they are ascertained facts?—For this reason: we want first of all to ascertain the quantity which would be delivered; of course the quantity delivered in the lower Thames to the quantity delivered in the Upper Thames Valley would bear the ratio of the rainfall in the one to the rainfall in the other.

13,738. That depends upon the geological conditions and other circumstances?—I am assuming that the geological conditions are the same, and I say, supposing the surface of the ground were of a similar character, and would allow all the rain to run off, then the quantity of flow you would gain by gauging at Teddington would bear to that which you would obtain in the lower Thames the proportion that the rainfall bore in the one to the other.

13,739. Assuming the geological character to be the same?—Yes, assuming the geological character to be the same. That being so, instead of 70,000 cubic feet a minute, furnished by the 1,486 square miles below Teddington, there should be delivered 121,230, being in excess of the 70,000 gauged by Mr. Baldwin Latham by 51,209, and that difference or loss is, as Sir John at once perceives, due to geological considerations, and that is the point I am coming to.

13,740. There are other besides geological conditions?—Yes, such as where the country is more or less wooded, and the slopes, and the time it would take to run down, and the soil, and the evaporation. Now I am going to show why it is that the water which falls over Teddington Weir is so much in excess of that which is obtained by gauging the Lower Thames. This is the published geological map (*producing a map*).

13,741. (*Chairman.*) You are going to show why the water which comes over Teddington Weir is so much in excess of what?—Of the rain, which is found by gauging, delivered by the surface to the Lower Thames. I say that the water which comes over Teddington Weir amounts to 94 cubic feet per minute per mile, whereas that which is gauged by Mr. Latham below amounts only to 47 cubic feet per minute per mile.

13,742. You do not impeach the accuracy of Mr. Baldwin Latham's gaugings?—No, certainly not.

13,743. Does anybody impeach the accuracy of the other thing?—I may tell you at once the drift of the whole thing, but I want to put the story complete upon the notes. I am going to show that a very large quantity of the water finds its way into the Lower Thames through its bed by springs, and that that makes a very important difference indeed in the ratio of the upland water to the lower. I would now call your Lordships' attention to this enormous bed of chalk which forms the basin of the Thames (*pointing to the plan*); it is coloured pale green. It extends also above the lower green sand, crops out all along the southern coast, lies under the channel, and occupies a very considerable part of France. Now, I think I may dispense with that plan, as I have another which shows the matter much more clearly.

(*Producing a map. See Appendix* BP). This is the index map of the Ordnance, 10 miles to the inch. I have coloured upon that the outcrop of the gault. The gault upon the line coloured blue is from two to eight hundred feet higher than the level of high water. On the Surrey side, in Kent, it is not so high, but still it is sufficiently high to form a basin; it descends to a depth of about 600 feet, and it is perfectly impervious to water.

13,744. (*Sir John Coode.*) You mean a depth of 600 feet below the sea level?—Yes. The chalk and the gault run beyond the Thames Valley towards the sea, but owing to the incline of the strata the water which falls upon the chalk within the valley of the Thames finds its outlet in the valley of the Thames. The whole of the space left white within the valley of the Thames is chalk, and upon the section which will now be laid before you, taken from Merstham to Dunstable, the gault forms a perfect watertight basin. The whole of the surface of the chalk is singularly free from rivers, and I will show your Lordship directly where numerous "swallow holes," as they are called, exist, absorbing enormous quantities of water, the 5,868 cubic feet per minute pumped up by the New River Company being only a portion of that water. Now immediately above the gault, and forming the green line, there is the upper green sand.

13,745. Is the line of that section marked upon this map?—It is not, but I will have it put on. I should say this section is reduced from Mr. Whitaker's section, the geologist who was called by the Corporation, and who is an eminent geologist attached to the Geological Survey. This is identical with his sections, except that if it were drawn to the natural scale it would occupy the length of this room, and would be very inconvenient; therefore, the scale is distorted. The portion of that plan which is coloured pink is the outcrop of the tertiary beds, which are pervious to water. The portion coloured grey is the London clay; that is impervious, so that you have an enormous reservoir of water imprisoned between the London clay and the gault; that is the first step.

13,746. That is the reservoir from which the London brewers derive all their supply?—Now, I wish to point out to you what happens with regard to all that water.

13,747. (*Chairman.*) Your object now being to show that there is a larger amount of fresh water in the Lower Thames than would be attributable to water coming over Teddington Weir and what falls from rain immediately above it?—Yes.

13,748. (*Sir John Coode.*) That is your object?—That is my object.

13,749. There is more than visibly flows into it?—That is so. The water which has entered into the bed of the river above Teddington from rain and springs has come over the weir and been gauged, but the water which enters silently into the Lower Thames by springs has not been observed and has not been estimated, and would very seriously affect the result.

13,750. (*Chairman.*) You have gauged all the river supplies, such as the Dart, have you not?—Yes, all the surface water has been carefully gauged.

13,751. But you want to say that there is a quantity of unseen water that goes into the Lower Thames?—There is. I am now showing how it comes to be so, and then I am going to give you positive evidence that it is so. The sections I have now put before you (*handing in sections Nos.* 27 *and* 28, *Appendices* A.S. 1 *and* 2), are sections taken at right angles more or less to the course of the river through the Thames Valley Section No. 27 is from observations of my own which were taken for another purpose and continued for a twelvemonth. The names of the places show where wells extending to the chalk were dipped at intervals to show the level of the water, and your Lordship will see that whereas the water stands at Tring at 453 feet above the Thames, it falls gradually until at Isleworth it is at the level of the Thames. It is always being supplied from above; it is always escaping into the Thames and into the sea round the margin of the coast, either into the bed of the river or the sea.

13,752. (*Sir John Coode.*) This would be much more valuable if you had a key plan showing the lines upon which the sections were taken, and also the scale of this large section No. 26. (*See Appendix* AT). The scale is not mentioned?—I will have the scale put on; it is drawn to scale; it was really intended as a diagram. Now, the amount of rain which is absorbed by these surfaces may be gathered from the fact that there are 3,794 square miles of chalk exposed which drain into the Thames basin. This is according to Mr. Prestwich, who is looked upon as the best authority upon that subject. If you take the lower tertiaries, the chalk, and the upper green sand, all of which are pervious and admit the rain, we have upwards of 4,000 square miles of country which is absorbing a large proportion of the water which falls upon it.

13,753. The total area of the Thames basin is how much?—The total area is 5,162, adding the two together.

13,754. (*Chairman.*) The upper and the lower Thames valley?—Yes, altogether. Now I would wish to point out this. In many parts, where either the gault or the London clay meet the chalk, the rivers which had been formed upon less pervious strata disappear, being absorbed by the chalk. The Mole is so called because of the swallow-holes which exist between Dorking and Leatherhead. At Canterbury a very large number of swallow-holes exist at Farnham there are a very large number; at Newbury, at Hungerford, and in the valley of the Lea between Hatfield and Barnet, there are a series of streams or rivers which have no outlet whatever, but disappear, and are the feeders of the Amwell Spring, which is in the neighbourhood. I have coloured upon the ordnance the streams as they exist. (*Producing a Map. See Appendix* BQ). They have no outfall into any river at all, and could not have been gauged by Mr. Baldwin Latham.

13,755. Do you find these streams come to an end, as it were?—Yes; at South Mimms and at Mimms they have no other outlet than being swallowed up in the ground. They are called "swallow-holes" or "swilly-holes," and there is a very large extent indeed of them in the River Mole. There are some of them near Canterbury 50 feet in diameter.

13,756. And the River Stour?—The River Stour is kept clean by the water which has fallen on to the chalk and escaped through its bed; it scours away the mud, and keeps it clean. Now, I do not wish to occupy time further upon that, but will put the references upon the notes, because I would wish to refer the Commission to a paper by Mr. Prestwich.

13,757. There is another thing, which may fairly be mentioned now, upon which anybody can judge for himself. In many of the chalk districts there are no streams, and if you look on the Ordnance map you will find that it is so?—Between the Ravensbourne and the Medway there are no streams of any consequence. The Dart and the Cray are very small streams.

13,758. (*Sir John Coode.*) The chalk may be compared to a sponge, in fact?—I have a plan which shows the sections No. 27 and No. 28; they are laid down by blue lines on the map (*Appendix* BP). This was prepared for another purpose.

13,759. (*Chairman.*) Your theory, I understand, is this. There is the water, and it must get away, otherwise that which fell upon the land would be visible?—It must get away, and we find that the level all round the margin of the river is at the mean level of the water.

13,760. May not some of it get to the sea?—An enormous quantity of it gets to the sea, and I am going to show the importance of that as bearing upon this question.

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

13,761. (*Sir John Coode.*) I conclude, from your last answer, that you have directed your attention to the points where it does get into the sea?—Yes. Directing you to where you will find it, I would refer the Commission to Mr. Prestwich's paper in the Proceedings of the Geological Society, volume 10, page 222, and to Mr. Long's paper in the Proceedings of the Geological Society, volume 3, page 101, and to Mr. Clutterbuck's paper in the Journal of the Royal Agricultural Society, volume 25, page 306.

13,762. Could you give us a summary of them?—These are descriptions of the swallow-holes which exist at Canterbury, at Barnet, and at Farnham. There is one point I should like to mention, which is important, viz., the variation of the water-level. In the section No. 27, during the whole of the year the levels varied from ·58 of a foot near the Thames to 18·9 feet near Tring. The water in the chalk varied with the season, with the rainfall, below that height, so that the hydrostatic head was a little greater at some times of the year than at others.

13,763. What is there in these sections?—That is the mean. I would refer you to Mr. Barlow's paper, read at the Institution of Civil Engineers on the 5th of December 1854. It is in the Minutes of the Institution, Volume 14, and I can very briefly tell you the general subject of that paper. It was a suggestion that a large quantity of the water which finds its way into the Thames from the chalk should be intercepted by galleries running parallel with the river, and used for the supply of London. It was a suggestion made by Mr. Barlow to the South-eastern Railway Company's directors, he being engineer at that time to the South-eastern Railway Company. Mr. Ansted, the celebrated geologist, also made a report, of which I have a copy here. I need not read it, but the general purport of that report is this,—It was stated by Mr. Whitaker that the chalk crops out in the river first at Deptford. The chalk is in the bed of the river, coming down as far as Windsor, and thence, from Windsor to Deptford it is overlaid by the London clay, so that no springs can escape into the bed of the river from the chalk for that distance, but at Deptford the chalk begins to appear, and the tertiaries also, and continue until you get down to Tilbury. Through that length of the river large springs come out into the river and are visible at low water at spring tides. The particulars are given in the report of Professor Ansted and Mr. Barlow of visible springs at near low water.

13,764. (*Chairman.*) Do you know any very remarkable one—any large one?—There are numerous springs near Greenhithe, and if the Commissioners choose, when they are going down a low spring tide, they might themselves see the springs running into the river.

13,765. (*Sir John Coode.*) Have you seen them yourself?—I have. Now Mr. Whitaker, at Question 7014, is asked, "What is the fourth set?" that is in the enumeration of the strata he had described, and he says, "The fourth is the chalk, the lowest bed we "get in this part of the Thames valley." Then he is asked "Where does that extend from and to?" To which he replies "That extends from Deptford right "down the valley, being occasionally hidden, however, "from just below Woolwich to near Erith, by some of "the beds just described. In the neighbourhood of "Woolwich and from just above Erith to below East "Tilbury the valley is wholly cut in chalk." That is Erith, Long Reach, and the river below. Then he is asked, "Is the chalk a very permeable stratum?" To which he replies, "Yes, as a rule it is, especially "the part with which we have to deal here, that is to "say, the upper chalk." Then in his re-examination he is asked, at Question 7042, "I understand you to "say that no doubt the chalk does at its outcrop get "a considerable amount of rainfall into it." To which he answers "Yes."

13,766. (*Chairman.*) What is that gault you referred to a little while ago, is it a sort of chalk?—No, the gault is a very strong clay indeed, from which gault bricks are made.

(*Sir John Coode.*) It is one of the most tenacious clays you can possibly find, almost of the consistency of marl.

(*Witness.*) I wish to refer the Commissioners now to Diagram No. 29 (*producing the same, see Appendix* AU). This is merely a diagram expressing Dr. Way's determination of chlorine. If you will remember, Dr. Way put in certain tables which gave the quantity of chlorine upon the 14th and 22nd September and the 30th November at high and at low water, and the lines there shown express as ordinates the quantity of chlorine, and your Lordship will see that instead of being continuous lines as they would have been, if the chlorine had been a mean quantity, they all of them become elevated at Erith in consequence of the spring water which is entering the river there, diluting the sea water and making it more fresh, it is observable in all of them. Having pointed out that, I now wish to show the influence that that would have upon the tables which were put in by Mr. Mansergh as showing the percentage of sewage existing in the river upon certain days. I want now to show your Lordship the practical bearing, but I would first, in referring to Mr. Mansergh's tables, point out that Mr. Mansergh has over-estimated the quantity of sewage. I do not know how it arose, but Mr. Baldwin Latham, at Question 7688, took it at 64,158,122 from Crossness, and from Barking 84,005,145, making a total of 148,163,267, and that would give only 23,706,000 cubic feet per minute, whereas Mr. Mansergh took 26,000,000, why I do not know, there was no explanation of that. You will observe, upon Table M 3, Mr. Mansergh says that the sewage discharged at Barking is calculated at 14,760,000 cubic feet, and at 11,240,000 at Crossness, making a total of 26,000,000, which is 9, or nearly 10 per cent. in excess of that which Mr. Baldwin Latham had estimated more exactly by taking the population and the estimated quantity of water delivered. I, however, make the estimate of Mr. Baldwin Latham too high, for I have already given you the population actually drained in 1881. According to the census, which was then, as I said before, 3,880,102. Taking the increase as estimated by the Registrar General, which may be considered to be very exact, because it is founded on the relative birth and death rate, we must add to that 2 per cent. to arrive at the population in December 1882, about the time when these tables were made.

13,767. (*Chairman.*) This case will not turn on a matter 2 per cent.?—No, it is not a question of 2 per cent., but when the calculation is followed, as your Lordship will see, it makes a difference of cent. per cent. in the amount of sewage; that is to say, that population, taking 5 cubic feet per day per individual, (and Mr. Baldwin Latham only took 31·5, 5 cubic feet being equal to 32·5) gives only 13,742 cubic feet a minute; whereas Mr. Baldwin Latham has taken 16,296, and Mr. Mansergh has taken 18,055, and 18,055 as compared with 13,742, is in that respect alone a very important difference. So much for the quantity of sewage. Now I want to ascertain the quantity of upland water, and I have to refer to the mode in which Mr. Baldwin Latham and Professor Unwin estimated the quantity of water which was to be found in the Thames at Crossness on any particular day. Mr. Baldwin Latham was asked this question by Mr. Bidder in reference to taking the same quantity of water flowing past Crossness at any given moment as that which was at the same time coming over Teddington Weir; he was asked at question 8301, "Is not that necessarily erroneous, for this "reason, that the river water which came over Ted-"dington Weir upon the 14th is not the quantity "that is mixed down at, say, Crossness, upon that "day, and would not be mixed down at Crossness for "several days to come." To which he replied, "But I do not admit it to be an error, for according "to the theory of propulsion, whatever is put in at

" the upper end would push out an equal volume at " the lower end of the river." Then he was asked, " Do you mean to say that if we suddenly alter the " volume of the water that went over Teddington " Weir, that would produce an instantaneous altera- " tion at Crossness." To which he replied, " Yes, " or very shortly, in proportion to the rate at which " the impulse can travel. If you put a quart of water " in a long channel or a short channel, a quart will run " out at the lower end."

13,768. If that were true, if you threw a bucket of water upon the top of a house it would be upon the ground without any interval of time at all?—Yes, but this is of immense importance, because it affects the whole results of all the tables put in, as showing the percentage of sewage at any given time in the river. Your Lordship will see the bearing of it, and I think your Lordship already sees that what is here stated to occur is impossible. I only wish to show that it was said.

13,769. The river is not a rigid thing, in which, if you push one end you move the other?—But it is as clear as possible in the evidence, and I will take Professor Unwin upon the same point. Then Mr. Baldwin Latham, further asked, " So you consider that " you are justified, however many miles there are " from Teddington Weir to Crossness, in adopting " the quantity of water coming in at Teddington " Weir, as representing an equal quantity of river " water all the way down the river. To which he replies " Yes, I am justified in that." Then Professor Unwin is asked in cross-examination at Question 9706, " Although it is quite true that a certain " amount of fresh water poured in at the head of the " tidal section of a river must displace an equal " volume past every section; that is to say, assuming " that the same amount of water is put in every day " at Teddington, it is true that the same amount of " water must be pushed past every section of the " river in 24 hours, if the river is in its normal " régime; but in the first place, it does not follow " that the water which is pushed past is that " amount of fresh water, it may be mixed water," and Professor Unwin answers, " It does follow that " the same amount of fresh water must be pushed " past every section," Then he is asked " Why is " that. I am dealing with 100,000,000 cubic feet " poured in every day at Teddington. 100,000,000 " cubic feet must pass every section every day, but " that need not be fresh water," that is the question; he answers, " It is the simple mathematical law of the " continuity of the tide, that if you take two sections " of a river, the external conditions of which remain " constant, the inflow at one end is equal to the out- " flow at the other, and, further the inflow of each " material at the one end," and this is most remarkable, " is equal to the outflow of each material at the other, " otherwise the condition of the river changes." Now I do understand what he says there; what he says is this. If I come to day and find the river with a certain definite quantity of water in it, and I analyse that water and find that it has a certain chemical composition, and I come a month afterwards and find the conditions unchanged, both as to quantity and as to quality, I can then affirm that for every pint of any substance that was put in at one end a pint must have run out at the other, and he is quite right as to that; but it does not follow that it will run out upon the same day as it was put in, nor will you ever come a month afterwards and find the Thames with the same quantity of water in it, nor of the same chemical composition. Then he is asked at Question 9713, " So that the introduction of that extra 200,000 " cubic feet of water at Teddington coming down in " the sudden rush of a flood instantly purified to that " extent the river 50 miles away," to which he replies, " It instantly purified, to the extent of the " travel due to the upland water, the whole of that " water down to Southend; that is to say, in the " period due to one tide. The effect of a larger " quantity of upland water coming in at the top is " that the whole of the water is displaced down the " river by so much from the top of the river to " Southend"; that is to say, in the period due to one tide.

(*Chairman.*) I cannot tell how the gentleman could have said that it did such a thing; common sense tells you it could not, though ultimately it may have been so, no doubt.

(*Witness.*) But I should like to put upon the notes the whole of the scientific facts in three words. If you have a channel with water flowing through it, that channel having a considerable length, and you pour a large additional quantity of water in at the upper end, the effect is to increase the inclination of the water and gradually to increase the velocity all the way; but to say that if I were to pour into the Thames at Teddington suddenly a thousand tons of vinegar a thousand tons of vinegar would run out at Southend, I do not think that would commend itself to your Lordship; but that is what is said here, and upon that theory of propulsion is based the whole thing.

13,770. (*Professor Williamson.*) Do you mean to say that it is said to run out at Southend at the same instant as it is put in at the top?—Yes, it is so.

(*Sir John Coode.*) I think it hardly bears that interpretation.

(*Mr. Beaumont Morice.*) It does not.

(*Witness.*) Professor Unwin not only says it does flow out at the same time, but that it is the same quantity of each material.

(*Chairman.*) You must put a fair meaning upon it; he cannot have meant more than that what went in must go out.

(*Witness.*) But it is the application he makes of it, that I am going to point out.

13,771. (*Chairman.*) There may be an addition to it, as you say, from subterranean or subaqueous springs?—But this has an important bearing, as I will proceed to show; in fact, if I proceed with it you will perceive in two minutes the bearing that that has. If, for instance, instead of taking the water which was coming over Teddington Weir upon the 14th I take the quantity which was coming over seven days previously, that being the first record that I have in Mr. Baldwin Latham's tables, I get then 144,824 cubic feet per minute as against 118,000. That makes a very great difference with regard to the relative volumes of sewage and land water. If I now deduct from that the water supply, and add the spring water at 51,000 cubic feet per minute, and the sewage——

13,772. I beg your pardon; you are not giving us the whole of the rainfall in the Lower Thames Valley, which you have supposed not to be evident?—No. What I am doing is this. I am taking the deficit which there was in Mr. Baldwin Latham's gaugings of the Lower Thames as compared with the Upper Thames, and after making due allowance for the difference in rainfall, as the main quantity of the water would be delivered from the springs in the lower part of the Thames, and I think I am justified in doing that; it is only reasonable to suppose——

13,773. I do not know whether we are to go into it, but have you made any calculation of how much of the water that falls invisibly into the streams runs into the sea, and how much runs into the Thames; have you formed any notion of that; some of it runs into the sea, I presume?—Yes. Inasmuch as the gathering ground extends from beyond the upper part of the Thames Valley, I consider that I am quite justified in assuming that the quantity which escapes into the river along the margin of the river is proportionate to that which falls in the valley of the Thames, being confined, as it is, by the gault basin.

13,774. I may tell you my difficulty, if it is of any consequence at all. I understand you to say that it is manifest that in all reason there is as much rain falls in the lower valley of the Thames as in the upper?—Not that. I take the actual quantity by measure, and it is less, and I allow for it being less.

13,775. From its being in the east?—Not only

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

that, but it is not so high as the Upper Thames gathering ground; it is the height of the ground which affects the quantity of rain.

13,776. You say that all the rain that falls does not find its way into the Thames?—That is obvious.

13,777. It must go, surely, part of it, into the Thames, and would, you say, part into the sea?—Yes.

13,778. You think it is important to establish that, because that would show a greater dilution of the sewage than would otherwise exist?—Yes, no doubt.

13,779. Have you at all estimated the quantity that gets into the river of the whole deficit, if one may use such an expression?—Yes, I have estimated that at 51,207 cubic feet per minute upon the data which are upon the notes.

13,780. What proportion of the whole is that; how much goes into the sea?—The proportion which would go into the sea would form a very large quantity. I only assume that it is that which falls upon the Thames Valley, and is not accounted for which finds its way into the river; but there is a very large gathering ground, which is really in the valley of the Thames, which I have not taken into account at all; and, moreover, it is reasonable to suppose, that the water falling upon the chalk finds its way as directly as it can; that it will not go to the coast at a point 40 miles distant when it can reach the Thames at 20 miles; and, I may observe, that these sections I have put in actually show the fall of the water toward the Thames.

13,781. (*Sir John Coode.*) That it had been governed by the direction of the line of least resistance?—I would rather put it by the line of greatest fall, that is to say, the steepest gradient.

13,782. (*Chairman.*) You would give it all to the Thames, except where the sea could fairly compete with it, so to speak?—Yes; and to that upon this subject of the chlorine tests, I would add the influence of the drainage, not only from the east of England, but a large proportion of the drainage of the whole of Western Europe falls into the North Sea, and causes the water of the North Sea to be very much fresher than what the chemists take it to be, or than what they take as their standard for the purpose of their calculations. They never found it so salt as they said it ought to be, but they said the difference was due to the existence of sewage.

13,783. Do you say that the water of the North Sea is far less saline than that of the Atlantic?—It must be so. You have the Rhine, the Elbe, the Scheldt; you have the whole of the eastern half of England; you have a considerable portion of Russia, the whole of Prussia, the whole of Denmark, the whole of Holland, the whole of Belgium, the whole of Bohemia, the whole of Germany, and the whole of Switzerland draining into it; and it is impossible to have the rainfall from those countries draining into the sea without making the water of that sea fresher than that of the Atlantic.

13,784. You have a biggish river or two falling into the Atlantic, the St. Lawrence, the Mississippi, and the Amazon?—Undoubtedly.

13,785. Still, do not let us get into the ocean; let us keep to the narrow seas; what have you to say next?—The result of that calculation of the quantity of water which I have shown is 193,683 gallons, is to reduce the per-centage of sewage which Mr. Mansergh put at 15 per cent. to 7·1 per cent; as I say, therefore, cent. per cent. and more than cent. per cent. difference. The result of my calculation of the proportion of sewage to upland water upon the 14th September is 7·1 instead of 15 per cent.

13,786. One really ought to understand you, because you have taken an infinite deal of pains with it; do just tell me this, what additional fresh water do you mean, except this sub-aqueous or subterraneous contribution to the Thames? What other water do you add to that which gets into it below Teddington, otherwise than on the surface?—None.

13,787. But how much do you put it at?—The difference which is made upon the calculation, first, in consequence of spring water having been increased, and secondly, upon the assumption which has been made that the water which comes over Teddington Weir instantaneously appears at Crossness; those two together, I say, reduce the percentage of sewage and upland water from 15 per cent. to 7·1.

13,788. I cannot understand how that mistake or error, as you say it is, that it instantly appears at Crossness, arose, because it appears there ultimately?—That is just it. If I, upon the 7th September, have 144,000 cubic feet of water per minute over Teddington Weir, and if it takes a week for that water to reach Crossness, which is the fact, then I have to deal with 144,000 cubic feet per minute instead of the quantity which was actually coming over upon the 14th, which was only 118,000.

13,789. But what does that matter; in that space of time there is an average quantity comes down?—It matters this, a very delicate chemical test is made upon which I shall have something to say directly.

13,790. You are referring to something which has been taken out of the water?—Yes, I am.

13,791. That on some particular day they took something out of the water, and said that on that day a certain amount of water was flowing over Teddington Weir, which was true, but you say they ought to have looked at what flowed over Teddington Weir the week before?—Yes, you will see it in an instant. Their case is this: By means of the chlorine we can tell how much salt water there is; that being deducted from the whole bulk, leaves us the quantity of upland water and sewage; the ratio of the one to the other determines the quantity of the sewage, and that ratio is disturbed by the corrected calculation of the water; that is the whole process simplified.

13,792. Do I understand that there was more flowing over on the day of the experiment than was flowing over the week before, and that it was the water of the week before which had got down to the site of the experiment?—No; there was much less flowing over on the day of the experiment, and they assumed that what had got to Crossness was due to that day, and not to the water of the week before.

13,793. (*Sir John Coode.*) I thought it was the other way; that they gave rather a longer period than you are giving?—That was a totally different matter.

13,794. Did not Mr. Birch's diagram give a longer period?—That was a totally different matter. Mr. Birch's tables went to show that it did not matter how you dealt with this question; it would always lead to the same result.

13,795. (*Chairman.*) I should have thought it was against you, because they were ascertaining the percentage of sewage, were they not?—No, they did not ascertain that; they assumed that what they did ascertain was the absolute quantity of sea water in the river. They said, by means of the chlorine we can say what is the absolute quantity of sea water. The rest is a mixture of river water and sewage. Then if the river water that was there was only 118,000 cubic feet instead of 144,000 cubic feet; it left so much more for sewage. Now, I will address myself to the chlorine test itself, and the mode of dealing with the chlorine test.

13,796. What part of the river are you now going to speak of?—I am going to speak first of the estimate that the Corporation witnesses gave of the quantity of chlorine which was in the sea water when it came into the Thames, and upon which the whole is based. They made this assumption, that the sea water which enters the river from the North Sea always contains 1,961 parts in the 100,000 of chlorine, and if we find a less quantity of chlorine in 100,000 parts in any body of water, the difference is upland water, and sewage in the river. Now I contend that the 1,961 parts is far too high an estimate, and I base that upon this.

13,797. But suppose they were right, what re-

sulted from it?—That it showed a much smaller quantity of sea water than was actually present.

13,798. But where? — Everywhere where they wanted to determine.

13,799. It goes up as far as Chiswick?—Yes; but in order to determine the quantity of sewage at any given moment in any part of the river, they ascertained the quantity of chlorine, and if they found that the quantity of chlorine was less than there should be in sea water——.

13,800. That is to say they said in effect, we will show you that sewage exists to a certain extent, even at Gravesend, because we will show you the constituents of the water, and that involves a certain percentage of sewage matter; that is one of their propositions, is it not?—Yes, it is one of their propositions.

13,801. Then against that you say, If they had put the matter right it would have shown a less proportion of sewage there?—Yes, that is so.

13,802. But inasmuch as you know the river, and, consequently can gauge the quantity that comes in of upland water, and the quantity that comes in from the bottom, what is the use of going into a speculation of this sort?—Because it is one of the grounds upon which they have based the alleged pollution of the river to the degree to which they show it to be polluted. You have positive statements here that the river was polluted. You have the statement made here, that at Crossness, upon the 14th September, the whole body of the river contained 11·7 per cent. of sewage. If that were so, it is a very serious matter, that more than a tenth, in fact, nearly an eighth, of the whole river was sewage.

13,803. Cannot you get that to a certainty by telling the quantity of fresh water that comes in as compared with the sewage with which it is mixed?—Yes, and that is just where this estimate of the spring water and so forth has such a very important bearing upon the question.

13,804. Your view would corroborate your notion of underground supplies?—Yes. Now I wish to refer to Professor Way's Table No. 2, put in by him, in which he gives an analysis of the sea water at Margate upon the several days, beginning with October 29th and extending to the 30th November, and the mean of the chlorine in the water of all those observations is not 1,961 but is 1,899, and on no single occasion did it ever reach 1,961. The highest was on the 2nd November 1852, when it reached 1,951.

13,805. I suppose that is a difference of between 3 and 4 per cent., is it not?—Yes. Then the lowest was 1,737 at Margate, the mean, as I said before, being 1,899. And that is confirmed again by the mean of certain observations which he gives to your Lordship, which, curiously enough, also come out at 1,899. Now, if we take the mean of the sea water at Brighton, at Penzance, and other places, and in the Atlantic, as given by Dr. Frankland in his Table No. 3, we get at 1,900, which is nearly identical with Professor Way's mean; and curiously enough in the mid-Atlantic Dr. Frankland gives only 1,800, so that there cannot be a shadow of doubt, taking the water coming into the Thames from the North Sea with all this land draining into it, and also the water coming into it from the chalk, as we know all round the coast it does, and as I know from personal observation it does—I say, to assume that the sea always contains absolutely 1,961 parts of chlorine to the 100,000, and that if upon any day you find anywhere near the Thames a deficiency in that amount, you must attribute that deficiency to land water, containing sewage, is, I think, an assumption not borne out—it is somewhat unreasonable. Now, so much for the quantity of chlorine in the sea. I now want to make a remark upon the quantity estimated to be in the river itself; certain days are taken the 14th September, the 22nd September, and the 30th November. I will deal with the 30th November. Drawing No. 31, (*See Appendix* A.W.) is a longitudinal section of the river from Southend to North Woolwich, and it shows the positions in which the samples of chlorine were collected upon the 30th of November. On this day, the 30th of November, only two samples were taken at each spot—one was taken as shown upon the surface of the water, one was taken at 20 feet below the surface of the water. In some parts of the river, as the section shows, the depth of the river is 80 feet. Between Gravesend and South end Pier you will see on the section a very deep part. We have here a distance of 27 miles, and we have the assertion made, that by taking two samples at Erith and two samples at Southend, a distance of 27 miles apart, and the lowest sample only extending to 20 feet below the surface, when some parts of the river were 80 feet in depth, you get a fair representation of the mean quantity of chlorine throughout the whole length of the river, with sufficient exactness to enable you to say positively what is the composition of the water, and to determine that there is so much sea water, and consequently so much sewage; that is the proposition that has been laid before the Commission. Now I wish to point out from actual observation, the variations which occur in the composition of the water, as regards chlorine in very short distances. The analyses upon which this table is founded will be put in before the Commission by the chemists, and of course it will be regularly proved; the samples are all numbered, and this table (*producing Table No.* 8) contains the localities, the date, the state of tide, the number and position of sample, the amount of chlorine found, and the percentage of difference between two samples taken within short distances and at small intervals of time. By "short distances" I mean either at the surface, and at the bottom, or in the middle of the river, and on one side of it, and at the same points within a few minutes. The variations in these cases shown by the table are 10 per cent. in some cases, and 36·6 per cent. in others.

*Table No.* 8 *was handed in, and is as follows:—*

TABLE showing the VARIATIONS in the QUANTITY of CHLORINE in SAMPLES of THAMES WATER taken within short Distances and at small Intervals of Time.

| Locality. | Date, 1882. | State of Tide. | No. of Sample. | Position of Sample. | Amount of Chlorine. | Percentage of Difference in Amount of Chlorine. |
|---|---|---|---|---|---|---|
| | | | | | Grs. per gall. | |
| Greenwich - | Aug. 15 | Low water. | 284 | North shore | 33·3 | 12·9 |
| | | „ | 283 | Midstream - | 29·5 | |
| „ - | „ | High water | 279 | South shore | 258·4 | 12·7 |
| | | | 281 | North „ | 291·2 | |

| Purfleet - | Aug. 26 | High water | 361 | Midstream surface. | 695·8 | 10·0 |
| | | | 360 | Midstream bottom. | 765·1 | |

13,806. (*Sir John Coode.*) You do not mean to say they vary from 10 per cent. to 36 per cent. at the same points, do you?—Very nearly. At Blackwall Pier on July 22nd, half ebb, between the surface and the bottom in mid stream it varied 12·7 per cent.

13,807. Were they taken at the same moment?—They were taken at the same moment as nearly as they could be, by the same observer, within three or four minutes. I have one taken near Barking Outfall, on August 3rd, at half-flood, where the difference between the surface and the bottom was 11·4, and I have one taken at Erith on the 27th July between the surface and the bottom, the variation being 20·6 per cent.

13,808. Do they seem to follow anything like a regular rule, varying according to the depth?—No, they are very much disturbed by the spring water coming in, and some of the variations which occurred in the analysis at Erith may be attributed to those two circumstances, the spring water and the depth.

13,809. I understand you to say that the variations are so great, that they must be attributable to something of the kind?—Yes, there are two things; the set of the tide, the flood tide cutting up through the river, and the spring water coming in and diluting the water of the river. Now I wish to call your attention to Diagram No. 32 (*producing the diagram. See Appendix* A.X.) Mr. Mansergh laid before you the tables to which I have previously referred, M. 3*d*, in which he shows you a certain quantity of sewage existing in the river at low-water upon the 30th of November, and he also shows that upon the subsequent flood tide, no sewage having been admitted into the river in the interim, there was an increase in the quantity of sewage between Southend and North Woolwich of 108,073,126 cubic feet or a discharge of 5½ days sewage from the metropolis, which must have come from the North Sea, so that 5½ times as much sewage is capable of coming in in one tide from the North Sea, as from the Outfalls of the Board. These figures were absolutely given by Mr. Mansergh. Column 10 being, at low water, added up, amounts to 297,600,583; while the succeeding high water of that same day, adding up column 10, comes to 405,683,709, or the difference I have stated, which is equal to the whole sewage of London for 5½ days, which must have come into the river miraculously.

13,810. Were they both at high water?—At low water, and the succeeding high water, no sewage having been discharged in the interim.

13,811. (*Chairman.*) Let me understand. You say that the evidence given against you shows at the time of high water five times as much chlorine as there was at the previous low water; is that so?—No, it shows 108,000,000 cubic feet more of sewage in the River Thames from the outfalls downwards at high water than there was at the previous low water, no sewage having been discharged in the interim.

13,812. (*Professor Williamson.*) Is it in the same or in a particular area of the Thames?—In the whole area, extending from Woolwich to Southend.

13,813. (*Chairman.*) Does it show that the chlorine in a certain district had augmented in quantity?—No, the assertion is this: here is a column which is headed "Quantity of sewage in each division;" that is the absolute quantity of sewage alleged to be there.

13,814. They have got at that from the quantity of chlorine?—They have.

13,815. Then you say to qualify that, that if that statement of theirs is right, it follows that there was 5½ days more sewage in the river at high water than at low?—A difference of 5½ days.

13,816. It follows that there was more sewage at high water, when nothing but fresh water from the sea had come in, and no sewage had come in, than there was before?—It does show that?

13,817. Is it a possible explanation that the sea could have returned the discharge?—Do you mean of the 5½ previous days?

(*Chairman.*) Yes.

13,818. (*Professor Williamson.*) Would you kindly state, because I have no doubt you have it in your mind, what proportion this bears to the total amount of sewage in the river; that is to say this 5½ days accumulation; is it an error of two or five per cent., or is it an error of 30 per cent.?—The Commission will see how I arrive at these figures.

13,819. (*Sir John Coode.*) But how do you arrive at the quantity of sewage being 5½ days?—By multiplying the quantity which is about 23,000,000 feet by 5½ it will come to about 108,000,000.

13,820. (*Chairman.*) Those figures show the bulk of water at high water?—Yes, they do.

13,821. They show the proportion of sewage in it?—They do more than that; they show the absolute quantity in figures.

13,822. They show the quantity of sewage?—Yes, they do.

13,823. You say that quantity is equal to 5½ days average discharge?—It is so.

13,824. Then, inasmuch as none had been poured into the river after low water, it follows that that must all have come back from the sea?—Yes, if it was there.

(*Professor Williamson.*) It is important to know what proportion this bears to the total quantity, and how many days are usually stored up in the river.

13,825. (*Chairman.*) Now, I will ask you this; of course the river is not empty at low water?—No; it would contain about half as much at low water as at high.

14,826. (*Sir John Coode.*) I understand you to say you there refer to Table M 3*d*?—In the divisions between Crossness and Southend, Mr. Mansergh alleges that there are so many million cubic feet of sewage in the river, in each particular division upon the date to which these observations refer. Then, I say, adding up the totals at low water and at high water when no sewage had been discharged, the

difference is equivalent to a discharge of five-and-a-half days of sewage.

13,827. (*Chairman.*) And the total quantity would be equivalent to 11 days, would it not?—No.

13,828. What I want to get out is this; half of it had not run out, you say, because at high water there was double the quantity of water in the river that there was at low water. Therefore, half the water had not run out, consequently, it is only half that had come in from the sea?—It is not half that came in from the sea; they allege that the quantity that was contained in the river at low water amounts to more than five days; they say that there were seven or eight days' sewage in the river at low water, but that at high water there were 12 days sewage.

13,829. Then it is about five days which had come from the sea?—That is all.

If you start with a datum of seven days sewage at low water, and find 12 at high water, you have five days coming back from the sea.

(*Witness in answer to Professor Williamson.*) I find it is just 36 per cent. of the whole quantity.

13,830. (*Chairman.*) Do you say that the witness's statement is wrong?—I say it is physically impossible; I will put it quite as high as that. This same diagram that you have before you will show that it cannot be. If you look to the upper diagram on your right hand, you will see a diagram to show the way in which the mean of the chlorine was taken. For instance, a sample is taken at the top of the water, and is found to contain 290 grains, a sample is taken 20 feet down, and is found to contain 338 grains; those are added together, divided by two, and that is called the "mean composition of the water." Now, if that is so, taking a water which increased in saltness from 290 to 338 in passing 20 feet down, by the time it got to the bed of the river they have assumed it to have got equally fresh to what it was at the surface, instead of increasing in the ratio that it did between 1 and 20 feet, and when you come to a depth of 80 feet in a length of 27 miles of river with all its varying circumstances, and trust to an observation at each end to give you the quantity of chlorine, I do think that observations founded upon that slender basis are not sufficiently accurate to draw such very important conclusions from.

13,831. (*Professor Williamson.*) There is one point which I should be glad if you would be good enough to inform me about, because you have the figures more clearly in your mind as given by the other party, what do you attribute to them as their view of the matter, as to the conditions of the river at high and low water respectively; do you take it to have been stated by them, that at low water the downward range of the sewage has the same proportional dilution as at high water at any particular point, that is to say, whether at low water when a great deal of the water that was in the river has run out, the sewage is found further down than it was at high water, that if it were the case that a good deal of this sewage mixture, which was up, we will say, at London Bridge, at high water, has gone, at low water, down towards the Nore, then at high water this stuff would come up again, and not water from the North Sea. Would that have been their meaning?—No, this must have been water from the North Sea, because the whole of the water in the whole length of the river is included in this valuation.

13,832. You mean that what gets beyond goes down channel and up channel?—That is so. Now the next question is as to the quantity of chlorine in the river water. We have had the quantity of chlorine in the sea water, and we now come to the quantity of chlorine in the river water and the sewage mixed. In the estimates which they have made, they have taken the river water as containing 1·7 parts of chlorine in 100,000, but the water which enters by springs, especially when it comes from underneath the clay (as the largest proportion of the chalk water coming into the Thames does come), contains from 30 to 5 parts in the 100,000 of chlorine. I have taken the mean of 10 as against 1·7, so that if we take the discharge over Teddington Weir upon the 14th September, which I allege was 128,734 cubic feet per minute, at 1·7 parts, and take the 51,000 cubic feet, which, I say, comes in at the springs at 10, it gives as the mean quantity of chlorine in the water four parts of chlorine in 100,000 instead of 1·7. If, therefore, we now apply the principle, which I do not dispute, I say the chlorine test is in theory a very beautiful thing, and undoubtedly is theoretically perfectly correct; if you have accurate quantities to deal with, and you know that they express the mean values, you will get an accurate result. I say if you apply it upon this basis you will get a very different result.

13,133. (*Sir John Coode.*) Do I understand you to say that the quantity of chlorine in these springs has been arrived at by the actual analysis of the springs in question, which are flowing into the Thames?—Some of them.

13,834. Because you will see that a great deal will turn upon that?—At page 103 of the Sixth Report of the Rivers Pollution Commission there are several analyses of chalk water, the nearest I find here is at Witham, in Essex, which I think we may take as the water which would be finding its way to the Thames.

13,835. But you have not got it at the point near where it issues into the Thames, have you?—I have one analysis of Professor Way's.

13,836. (*Chairman.*) Do you say that the water at Witham would find its way to the Thames?—It is the water which is already on its way to the Thames; it is water from a well which is then flowing to the Thames.

13,837. (*Professor Williamson.*) Do you assume that after percolating through a considerable thickness of soil, it would be of the same composition as on entering?—These are analyses of the water from the wells.

13,838. That is where it goes in?—No, this is where it is taken out at Witham.

13,839. But you are assuming, are you not, that this water, as I understand at Witham, soaks through chalk or soil so as to get to the Thames?—No, I am not. Witham is one of the points of outlet, Witham lies low, and Witham is one of the points of escape. We have another example at Braintree, in Essex; there there were 38·8 parts of the chlorine in 100,000 parts.

(*Sir John Coode.*) The point is the constituent parts of the water where it absolutely flows into the Thames; that is the point I want to be clear about.

(*Mr. Beaumont Morice.*) From Witham would be some distance round to get to the Thames.

(*Witness.*) Thére is no fact better known, as shown by these analyses, than that where you have a water from the chalk from underneath the clay, it does contain these large quantities of chlorine, and that that is the exact condition in which the water which flows from the Thames does flow in.

13,840. (*Professor Williamson.*) That it usually contains 10 parts in 100,000?—It usually contains 15; the 10 is the mean.

13,841. And at Braintree?—At Braintree it is 38·8.

13,842. Have you any analysis of the water, as it is flowing into the Thames?—Not as it is flowing into the Thames, but I have from the South Essex waterworks, which are close to the point of the water flowing into the Thames, and from Professor Way's analysis it is 13·3 to 13·6 parts in 100,000.

13,843. *Sir John Coode.*) And that is pumped from a deep well, whereas the water at Witham is on the surface, if I understand you rightly?—No, the water there is in a deep well.

13,844. If you could give us the proportion of the chlorine in the water as it flows immediately into the Thames, that would be the point which I should like to have?—That might be taken.

13,845. (*Chairman.*) Where did the other side take their samples from; were they taken from water flowing over Teddington Weir?—Yes, they were

*Mr. H. Law, M. Inst. C.E.*

29 May 1883.

taken from water flowing over Teddington Weir, which gave 1·7.

13,846. (*Sir John Coode.*) I must say that for my own satisfaction I should like to have the water analysed at the point where it goes into the Thames; anything else is an inference?—Now, pursuing exactly the same calculation as that adopted by Mr. Mansergh, the result is, that instead of showing upon the 14th September 8·9 per cent., as he does show, in Table M 3*b*, in the division immediately below Crossness, as the quantity or percentage of sewage in the river upon that day, I make it 4·19, which is again just about cent. per cent. difference. Again, I would call the attention of the Commission to the fact that although Mr. Birch brought out a diagram in which he said he had not taken the rough-and-ready way of arriving at the result, which Mr. Mansergh's and Mr. Baldwin Latham's experience had enabled them to do, but that he had gone into it with greater exactness, I have compared the results which he so gives with the results of Mr. Mansergh's table for the 14th September, taking the six divisions below Crossness. I will not read the figures, but the result is this, that in the first division Mr. Birch's estimate is 8·9 per cent. more, in the next 3·31, the next 5 per cent., the next 14 per cent., the next 39 per cent., and the next 44 per cent., in excess of Mr. Mansergh's estimate upon the same day; Mr. Birch's average of the whole length of the river from Crossness to Southend being in excess of Mr. Mansergh's estimate by 16¾ per cent., whereas Mr. Birch said he had brought his forward to confirm Mr. Mansergh's. If you take the absolute quantity of upland water and sewage as given by Mr. Birch and Mr. Mansergh upon those days, the differences vary from 1½ per cent. less in the third division, to 20 per cent. more in the fifth division. Then if you take the percentage of sewage to upland water, that varies again in Mr. Birch's estimation and Mr. Mansergh's from 4 per cent. to 20¾ per cent. Those are the discrepancies in the figures given by two estimators upon the same data. Then I observethat in these tables of Mr. Mansergh's, lettered M, he assumes that in every case the quantity of upland water is constant from Erith downwards, whereas Mr. Baldwin Latham makes it increase upon the 14th of September by nearly 7 per cent. Mr. Mansergh makes the quantity of upland water and sewage in his column 9 constant every day for 27 miles of the river below Erith; he makes it the same at Southend as at Erith, and the same at high water as at low water. It is absolutely impossible, that is to say, thatt he proportion of the upland water to the sewage water never varies during the 24 hours; that whether you are at Erith or at Southend, whether the sewage has been discharging into the river, or the sluices are shut, that the percentage of sewage to upland water is always the same; it is quite impossible.

Adjourned to to-morrow at half past 12 o'clock.

---

# THIRTY-SIXTH DAY.

## Wednesday, 30th May 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
JAMES ABERNETHY, ESQ., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

MR. HENRY LAW called again; further examined by MR. NORMAN BAZALGETTE.

30 May 1883.

13,847. I believe, first of all, you wish to add something or to say something about the observation you made yesterday with respect to the capacity of the outfall sewers?—I wish to say that we have since ascertained the quantity of rain which fell last Saturday. I find that between 9 in the morning and a quarter after 12 in the day $\frac{17}{100}$ths of an inch of rain fell, and between half-past 4 and 6 o'clock $\frac{15}{100}$ths, making together $\frac{1}{3}$ of an inch in 9½ hours, and that although only two out of the three sewers were at work, no overflow occurred at any part of the system.

13,848. (*Sir John Coode.*) Was there nothing falling between 12 and half-past 4?—Yes; these are the observations made at Spring Gardens; and being at the outfall myself I can say there was a drizzling rain during the interval. The system, therefore, which was provided for a quarter of an inch in the 24 hours with the three sewers was sufficient to take the rain at the rate of one-third of an inch in nine hours when only two of the sewers were at work, and no overflow occurred at any part of the system, and that rain was running off during the period of the maximum flow, because the maximum flow was at half-past 2.

13,849. (*Mr. Norman Bazalgette.*) When we broke off yesterday, we were speaking upon the subject of the chlorine tests; have you anything to add to what you said yesterday?—I would first hand in Table 8*a*, showing the difference between Mr. Birch's and Mr. Mansergh's estimates of the sewage in the river below Crossness, to which I referred yesterday.

[*The Table No.* 8a *was handed in, and was as follows:*—

COMPARISON of the Estimates of Mr. BIRCH and Mr. MANSERGH of the quantity of PREVIOUS SEWAGE in the Six Divisions of the River below CROSSNESS, on the 14th of September 1882, as determined by the Chlorine test.

ABSOLUTE QUANTITY of PREVIOUS SEWAGE.

| | Mr. Birch's estimate. | Mr. Mansergh's estimate. | Percentage of difference upon Mr. Birch's estimate. |
|---|---|---|---|
| 1st division - | 140,400,000 | 152,913,468 | 8·91 per cent. more. |
| 2nd " - | 137,800,000 | 142,360,747 | 3·31 " " |
| 3rd " - | 117,000,000 | 123,041,069 | 5·16 " " |

| 5th „ - | 12·93 | 15·00 | 16·01 „ „ |
| 6th „ - | 12·42 | 15·00 | 20·77 „ „ |

Then I would point out that another circumstance which would appear to throw some doubt upon the conclusions drawn from the chlorine tests upon the 14th September, would be that they show that at St. Paul's Pier at high water there was 12 per cent. of sea water there, which is almost an incredible thing. Up to a few years back the Lambeth Waterworks took almost the whole of their supply from a point close to Waterloo Bridge, from a point very little above the point where it was alleged that the water was liable to have 12 per cent. of sea water in it. I do not think therefore that it could ever be so. I have only one more matter to add with regard to the chlorine tests, and that is a short calculation as to the result shown by Table M3*C*. of Mr. Mansergh. Referring to Table M3*C* it is there shown that in the 6th Division, that is the last division above Southend, there were 13,686,000,000 of mixed water, and that is stated to contain in each volume (that is dividing it by cutting off five noughts) 1,700 parts of chlorine. If therefore we multiply that number by the 1,700, we shall obtain the quantity of chlorine that was contained in the whole quantity of water in that division. If we then deduct from that the quantity alleged to be in the sewage, there were alleged to be 600 volumes of sewage containing each 10 parts; that gives 6,000 parts of chlorine. Then, again, if we take the quantity of sea water alleged to have been there, which is 118,000 volumes, and multiply that by the 1,961 parts which are stated to have been the quantity of chlorine in the sea water, those two last amounts deducted from the preceding leave the volume of chlorine in the sea water, which must have existed in that part. If we now divide that by 1·7, which is the quantity of chlorine alleged to be in every volume of land water, we arrive at the fact that there must have been 61,000,000,000 cubic feet of upland water, which is 34 times the quantity which Mr. Mansergh states in another column to have been there; four times the whole quantity of water in that division of the river, and 40 per cent. in excess of the whole quantity of water in the river from Teddington to Southend.

13,850. (*Chairman.*) I should think you have not the slightest hope or expectation that I understand a word of what you are saying, have you?—It is a simple calculation, which your lordship will have no difficulty in following when it appears on paper.

13,851. Although an accomplished mathematician might understand it, and I claim some small acquaintance with figures myself, would it not be better that you should state your conclusion, and give your reasons for it?—I am doing so. It proves that if the slightest value is to be attached to this table, the upland water in the river was 40 per cent. in excess of the whole of the water there.

(*Mr. Lumley Smith.*) It proves that the table was wrong.

13,852. (*Chairman.*) It shows that all the water there was what?—That it must have been river water, and a good deal more as well. I put that proposition before you, it is for the other side to contradict it. I say the test is one of such delicacy that it is impossible to draw any conclusion from it, except that they have been unable to take such an enormous number of observations simultaneously as to enable them to give you accurate data; but to take observations as they did at Southend and at Erith only, and then to assume that that gave them the whole composition of the water in the 27 miles intervening, it is that which upsets the whole conclusions of the table.

13,853. It goes to show that there was 40 per cent. more water than there was there?—Yes, if the table is right, that is the inevitable conclusion.

13,854. It practically comes to this, that the table is wrong?—Yes, the table must be wrong. Now I have only one word to say with regard to Professor Unwin's tables, and that is this: the tables of Mr. Mansergh, Professor Unwin, and Mr. Birch professed to give you results drawn from the same data in confirmation of each other; but if we compare them, taking only one day, the 14th September 1882, at high water, Mr. Mansergh states the total volume of the river above Crossness to have been 4,211,000,000, Professor Unwin states it to have been 4,397,000,000, or 4½ per cent. in excess; but if we take the total volume below Crossness we find the percentage in excess on the part of Professor Unwin over Mr. Mansergh is 27 per cent., which, is a very important difference; those are the errors in Table 2, they affect Table 3 and Diagram No. 1. Then Table No. 4 is entirely fallacious, because in it is assumed the theory of propulsion, which as I explained yesterday, is inadmissible; and the fallacy in Table No. 4 affects the whole of the subsequent tables. Then taking the same high water, comparing Mr. Mansergh and Professor Unwin, we find the total sewage in the river above Southend, according to Professor Unwin, is 15 per cent. in excess, and we find, if we compare the sewage above Southend at low water with the sewage at high water, while Mr. Mansergh makes it 13,000,000 less at high water, Professor Unwin makes it 10,000,000 more.

13,855. (*Mr. Lumley Smith.*) More than what?—At high water than at low water.

(*Mr. Norman Bazalgette.*) Now we will go to another point, what do you say as to the capability of the river to purify the sewage discharged into the river.

(*Sir John Coode.*) This I suppose is in respect to volume, not chemically.

(*Witness.*) No, not chemically, beyond merely stating the quantities. I do not profess chemical knowledge, or to deal with the subject from a chemist's point of view. Now Dr. Tidy told us, reading from page 11 of his paper laid before the Chemical Society on River Water: "On the other hand, I contend, if "sewage be discharged into a river in such proportion "that the pure water is at least 20 times the volume "of the sewage, that, after a moderately rapid flow "of a few miles, the whole of the impurities will by "oxidation and other agencies disappear, and the "water be again restored to its original state of "purity"; and at page 20 of his paper he sums up in these words: "Given then a fairly rapid river that "has received sewage in quantity not exceeding, say, "one twentieth part of its volume, is there evidence "to prove that after the run of a few miles the water "of that river will regain its purity and become "wholesome and good for drinking? To this "question I answered unhesitatingly, there is "undoubted evidence of such purification; and the "evidence I have adduced has been of a fourfold "nature, physical, chemical, medical, and statistical." Now I made a calculation to enable me to tell what proportion of pure water you would have to receive the sewage poured into it at the outfalls. The first element in that calculation is the quantity of water which will pass upon the ebb tide, and I have taken an average ebb tide, viz., that which occurred upon the 3rd of October 1882, when I find that almost all the conditions were those of an average tide midway between neaps and springs, and when the upland water at Teddington was at its average value or quantity. In order to determine the quantity of water which will flow out in a tide, we want to know the exact level of the surface of the water when it is high water at Crossness, and we want to know the exact level of the water in the river when it is low water at Crossness; and it is perfectly evident that

*Mr. H. Law.*

30 May 1883.

the whole bulk of water contained between those two planes with the water coming over Teddington Weir during the seven hours of that ebb tide must be the quantity which passed Crossness and Barking upon that tide. I have a diagram here (*producing a diagram*; *see Appendix BO.*) upon which the heights are plotted to the tenth of every tide, from tidal observations which were taken by the registering instruments, and which enable me to calculate with accuracy the volume of the water so discharged; and I find it to amount to 2,523,000,000 cubic feet. I add to that the upland water, which entered the river during the seven hours between high and low water, which I find amounted to 61,900,000 (I do not take the small figures), giving me a total of 2,585,000,000 cubic feet as having passed. The sewage discharged in one tide amounts to 9,894,000, being half a day's discharge, and that bears a ratio of 1 to 261 as compared with the river water.

13,856. (*Mr. Lumley Smith.*) Would you kindly tell me how you got your calculation of the difference between high and low water mark?—The mode of obtaining that was by calculating the volumes contained between the high and low water space for each successive length of the river starting from Teddington and going down to Crossness, a work involving some thousands of figures, but which has been done with accuracy.

13,857. (*Chairman.*) Let me see if I understand you; the water in the river at high water is of a certain height, at low water it is of a different height, the quantity of water between those two heights must have gone away?—That is so, *plus* that poured into it from other sources, which has also passed through it.

13,858. I do not see the "*plus*" so very plainly?—If I have a cistern, and I lower the water in that cistern three feet, I take out three feet of water; but if I have poured in a foot during that time, I must have taken out four feet, although lowering it only three feet.

13,859. Except that there is this difficulty, that you will have the tide running up in one part of the river while it is running down in another. How you make it as 1 to 260 as the amount of sewage to water, and Dr. Tidy says 20 times as much is sufficient for purification?—That is rather too rapid a calculation; you have to bear in mind that Dr. Tidy said that you are pouring it into water already contaminated with sewage.

13,860. That is the question I am going to ask you—otherwise, if it were one discharge of sewage only, it would go into 260 times its volume of water?—Yes, or 13 times as much as Dr. Tidy seemed to think was necessary.

13,861. (*Mr. Lumley Smith.*) You have the diagram there, would you supply us with a copy of that; that would show us the number of divisions into which the river has been divided for the purpose of giving the level at each point?—No, it would not show you that entirely; you will have an opportunity of asking me that in cross-examination. It is precisely the same operation as Mr. Mansergh carried out to give the quantity of water discharged from an isochronous line. It is the same principle, only Mr. Mansergh took the high water at Southend and I took it at Crossness, because that is the point which affects this inquiry.

13,862. You would have no objection to let us have a tracing of it?—Not the slightest, the tide has been divided into ten parts for other purposes. Now if we divide 261 by 20, then we get 13, and it therefore results that unless the river contains 12 days of unaltered sewage it would be competent to purify the sewage.

13,863. (*Chairman.*) 12 tides, would it not be?—Yes, 12 tides it should be. Then Mr. Mansergh told us, in the table which I referred to before, that on the 14th of September the percentage of sewage contained in the river at high water at Crossness was 6·4 per cent. of the whole volume, and at low water 8·7 per cent. I am taking the figures in column 11 of Table M3*a*. But now referring to Dr. Frankland's Table 9, which gives the actual chemical composition of the water in the river at North Woolwich immediately above the sewage outfalls on that day, I find it there stated that the organic carbon was ·366 in 100,000 parts, and at low water ·34, while the nitrogen was ·123 at high water, and at low water ·121. Now comparing that with the filtered water delivered by the water companies for drinking purposes in London, the water here is nearly as pure.

13,864. At what spot do you say?—At North Woolwich, the division immediately above the sewage outfalls, that is to say, the water which is going to pass down to receive the sewage. I take that division, because that is the water just going into the sewage. If I had gone up above, it would have been purer; but I speak of the water which is immediately going to receive the sewage.

13,865. (*Sir John Coode.*) What was the condition of the tide at this time?—I have taken high and low water. At high water it is ·366 of carbon, and at low water ·34, there being a difference of only one and half hundredth. Now referring to the analysis of the water as published every month by Mr. Crookes, Dr. Odling, and Dr. Tidy, furnished to the President of the Local Government Board, I find that upon the 7th December the Southwark and Vauxhall Company delivered water containing ·37 of carbon, or a little more.

13,866. (*Chairman.*) What have we to do with what water the people are drinking?—I am going to show that of this description of water you will have 260 times the bulk instead of 20 times the bulk diluting the sewage.

13,867. But did they say that it was always as pure as that at North Woolwich?—It is upon this day that they say the water is more impure than on any other of those taken, in consequence of there being only two-thirds of the flow at Teddington of the average flow during the whole year, so I purposely took the day upon which the Thames was alleged to be most impure. Upon the 30th of November it only contained 2·78 of sewage to the whole volume, as against 8·7 on the 14th September. I have therefore taken it when they say the river was in its worst state only containing two-thirds of the average upland flow, and upon that day we find the water at North Woolwich, nearly as pure as the drinking water supplied to the inhabitants of London, and therefore capable of purifying the sewage which was delivered to it in the proportion of $\frac{1}{260}$th part of its bulk.

13,868. Do I understand you to say that people might drink with impunity, and possibly without disgust, the water at North Woolwich upon that day?—Yes, at low water certainly; at high water it would have been a little salter.

13,869. At what state of the tide was that, was it when the tides were taking off, diminishing towards the neaps, do you know?—It was a day or two after the spring tides—when the tides were falling off a little.

13,870. That is the time when, according to the evidence, the overflow is greater than the inflow. What they say—and it is obviously true—is that when the tides are taking off, the sewage does not come back so high up the river as it does when the tides are making; indeed, I do not know that it would come up at all?—Some of the latter part would—that discharged towards the half ebb.

13,871. When the tides are taking off, it does not come up the river so high as when they are making?—That is so.

(*Mr. Lumley Smith.*) Simply as relates from tide to tide, it always is oscillating up and down.

(*Chairman to Mr. Lumley Smith.*) The truth of your float experiments was admitted to a certain extent—it was admitted that a float put in at Crossness would, when the tides were making, be higher up at the same state of the return tide than it was when it was put in, and that when the tides were

taking off, it would be lower down; do you know what the tides were doing then.

(*Witness.*) The tides were taking off, it was in fact just about an average but I take their own valuation of the sewage according to their own test and their own statement.

13,872. (*Mr. Lumley Smith.*) You are still taking the 14th of September?—I am still taking the 14th of September, and the river is stated then to be more than twice as impure as it was upon the 30th day of November. Mr. Baldwin Latham has given us three comparative tables, the 14th and the 22nd days of September, and the 30th day of November. Upon the 14th the flow over Teddington Weir was in round numbers about 80,000 cubic feet a minute, and then the river was most impure.

13,873. (*Chairman.*) This appears to me to be a mistification of some sort or other, for your own witnesses, if I may say so, that is to say the medical men from Woolwich, say, that when they cross the river the stench is most offensive occasionally—according to your account it ought not to be, in fact, you say that it is not, and almost that it ought to be drinkable?—It is the only evidence we have got so far—it is evidence put in by the other side.

13,874. It is unintelligible to me, because your own witnesses sometimes describe it as something that is positively loathsome when they are crossing in a steamer, whereas you say that it ought to be drinkable?—The river water at Woolwich, as far as my experience goes, is never in a stinking state.

(*Mr. Norman Bazalgette.*) With all deference to your Lordship, I do not think our witnesses said that that was the rule, but they said that on certain exceptional occasions they had smelt it.

(*Chairman.*) They did not say that was the rule—they said it was free from smell in the winter, but what I understand from Mr. Law is, that according to the evidence given upon the other side, it never could be a stinking river.

(*Witness.*) There are so many other stinks in that neighbourhood, it must be remembered, that it is very difficult indeed to say that; but I would venture to ask your Lordship to keep your mind perfectly open upon that point until you have some personal experience. I think that would be far more satisfactory to your Lordship.

(*Chairman.*) I quite think so too.

(*Witness.*) Therefore the result at which I arrive is simply this: that if you take 20 parts of pure water as delivered by the Southwark and Vauxhall Company, and mix that with one volume of sewage, because certainly that is pure enough to purify it, the mixture would often be less pure or less diluted than when mixed with the 261 parts of Woolwich water with which the sewage really is diluted at the time of its discharge.

13,875. (*Mr. Lumley Smith.*) That I understand, if I might ask, is based on Dr. Frankland's tables entirely?—Yes, upon Dr. Frankland's Table 9. I then pass on to the amount of oxygen. I would call your attention to question 12,289, which was put by Dr. Stevenson to Professor Way, he is asked: "Then "there is the mineral matter in the urine, which is about one fifth"; and he says, "Yes, that is a good "deal. I do not wish to overrate the matter. I will "put it in this way: If I take the fæces alone and "say that 100 tons of oxygen are wanted, it is an "enormous quantity to be obtained to bring to the "surface of the river to be changed for something "else; and my belief is that if it were possible that "the whole of the sewage should be burnt up day "by day as it went in, the air of the neighbourhood "would be irrespirable; all the oxygen would be "gone." That, of course, from Professor Way requires great consideration. I have therefore made this calculation. The sewage admittedly travels 12 miles, sometimes 15 miles, in its passage down the river, and it travels at least 11 miles back, at Spring tides it comes up the whole 12 again.

13,876. (*Mr. Abernethy.*) I may take it for granted that it all passes down, that no part is deposited?—The part deposited could not be oxidised by the atmosphere. Now the mean superficial area of the river 12 miles below Barking, that is to say, the mean between high and low water, is 151,000,000 square feet, and each cubic foot of air contains 123 grains of oxygen, so that a layer of air only one foot thick would contain 1,189 tons of oxygen; and then, taking the 11 miles back, the superficial area would be 138,000,000 cubic feet of air, which at the same rate would contain 1093 tons of oxygen, making altogether 2,282 tons of oxygen, or 46 times the quantity required; and if it did not take up the oxygen for more than a foot, it would not affect the atmosphere of the people breathing it in the neighbourhood. That only shows how very dangerous a thing it is to make random statements without making a calculation.

13,877. (*Chairman.*) Is it supposed that it is the atmospheric air which oxidises the sewage?—No, but it has this very important influence; if I have water containing its full quantity of oxygen, that is 2 cubic inches to the gallon, it will not absorb any more. If I, from any cause, deprive it of half its normal quantity, it sucks it in from the air with avidity, just as a sponge does water. Now if I take the oxygen of the water into which the sewage is discharged, a cubic inch of oxygen weighs ·3438 of a grain. Then if one gallon of tidal water at the outfalls contains an inch of oxygen, and, referring to the tables of analysis, we find it contains upon the average at least an inch, we shall have 354 tons of oxygen in the water itself, or seven times the quantity required before it has to take any from the air; and that is in the diminished condition of the water as it approaches the outfalls. Then what do we find, if we find the water as it approaches the outfalls has one inch to the gallon of oxygen, and if we examine it when it reaches Erith and find it only has ·42 of an inch, the inference is that the balance has been used in burning up the sewage, the deficiency proving that it has done its work.

13,878. I thought it was alleged upon your side that the unscientific fishes would die in spite of the oxygen?—That is precisely what happens, it is the oxygen being taken out of the water to purify the sewage which prevents the fish living. One thing or the other must happen, either the oxygen must be taken to purify the sewage, or it is not; if it is not, the fish would live and the human beings would suffer, but the fact is the reverse—the fishes suffer and the human beings do not.

13,879. (*Sir John Coode.*) When you take the quantity of oxygen in the air a foot above the surface, you only use that as an illustration, you do not put that as a fixed quantity?—No, the air is always being changed by winds and otherwise.

13,880. (*Mr. Norman Bazalgette.*) You have given some attention to the subject of deposits in the river, have you not?—I have.

13,881. What do you say to them?—I say, first of all, the Thames must be a muddy river, no river under the condition of the Thames can be other than a muddy river. When, in Queen Elizabeth's time, it was devoted to swans and pleasure barges, it might have been a clean one, but with the enormous commerce carried on upon it, and the changes which have been made in it since then, it must be a muddy river.

13,882. (*Chairman.*) You mean in the region of the metropolis?—I do; I mean as high up as Westminster Bridge, where the traffic is so large and the water kept in such continued agitation, that it is impossible for it to settle, and it is therefore always in a muddy state more or less, varying considerably. Now I would first refer to Dr. Frankland's Report, because Dr. Frankland attributes the mud in a very large measure to the sewage outfalls. He put in a report, with copious tables at the end, which showed that there were upwards of 1,000,000 tons of sewage poured into the river through the outfalls every year. The first observation I would make with regard to this report is this——

*Mr. H. Law.*

30 May 1883.

13,883. Do you say 1,000,000 tons of solid matter?—Yes, of suspended solid matter. The first remark I would make is that these tables have not been prepared with sufficient care to warrant their receiving much consideration. Table B, which purports to give the quantity of suspended matter contained in the sewage according to the heaviness of the rainfall (those quantities being derived from various authorities) I find contains errors. For instance, in Table B, at page 18, I find that the discharge from the Savoy Street sewer upon the 11th of June is taken twice over, and therefore affects the average.

13,884. (*Sir John Coode.*) Our attention was called to that?—Yes, but I am calling attention to that to show the bearing it has upon this table, and the value of the results at which they arrive. Then I find it stated on that day "very slight rain, not measurable" but on referring to the actual authority, so far from its being a very slight rain, and not measurable, I find that upon the day before, in six hours preceding midnight, $\frac{3}{100}$ths of an inch fell, and from midnight to noon of the day itself $\frac{65}{1000}$ths, and that consequently $\frac{15}{100}$ths of rain fell in 18 hours, which was very nearly the maximum provided for in the sewers of Sir Joseph Bazalgette, if the storm overflows were not to come into play. Therefore it was a very heavy rain indeed, and not so slight a one as not to be measurable; that of course affects the way in which these quantities are to be dealt with. Then I find, again, Messrs. Hofmann and Witt are quoted as being an authority for the discharge of 209 grains to the gallon of matter discharged from the Savoy Street sewer upon the 20th June, but I can find no such figure at all in Messrs. Hofmann and Witt's Report.

13,885. (*Chairman.*) Was this an overflow discharge?—No, this was from the sewers.

13,886. Into an intercepting sewer?—No, this was before the intercepting sewers were made; this was in 1857. And then, also, I may say that the value of these tables is quite destroyed, owing to the fact that when these observations were taken in 1857, the sewers were in a totally different conditions from what they are now, and that the catch pits, and the system of preventing mud from going down into the sewers, was not adopted then as it is now.

13,887. Dr. Frankland, I think you say, says that the sewers discharge 1,000,000 tons per annum of solid matter; what do you say it ought to, I want to ascertain that?—I have not gone into that.

13,888. You merely say they are wrong?—Yes.

13,889. Because I dare say Mr. Lumley Smith would give you 10 per cent. rather than fight it in detail?—No doubt, but I am coming now to a much more important point. The principle upon which these tables are calculated is, as I said yesterday, that Dr. Frankland assumes that $\frac{4}{5}$ths of every drop of rain which falls, however slight the fall may be, goes into the sewer. I did not exaggerate when I said that, because what do I find when I turn to the table? He says there were 191 days in the year when there was no rainfall, and when there were 131,000,000 gallons of sewage discharged in the 24 hours, each of those gallons containing 23 grains of solid matter. In that I concur. But his next step is this; he says that upon 32 days $\frac{1}{100}$ths of an inch of rain (which is the thickness of a sheet of paper) fell in 24 hours, and he deliberately states that the effect of that rainfall, amounting to the thickness of a sheet of paper, was to increase the flow of the sewage at Barking by 14,000,000 gallons. Now I say not a particle of it could have reached there. Then he says that it had the further effect of increasing the proportion of solid deposit in every gallon from 23 to 42·9, and upon those data this table is calculated.

13,890. (*Mr. Lumley Smith.*) Have you the reference to his answer?—No, it is from his table, which speaks for itself. Now that is an incredible statement, of course, because it requires a great deal more rain than that ever to reach the sewers. A shower of rain which in 24 hours would only amount, if the surface were perfectly impervious, to a depth of $\frac{1}{100}$th of an inch, could never reach the sewers; if it were to travel over any surface it would be dissipated by evaporation, it certainly never could travel and carry double the quantity of solid matter with it. Having made that observation to show that the sewers do not contribute the enormous quantity which Dr. Frankland supposes, I now proceed to examine what are the sources from which the mud really is derived, and I would refer to an answer given by Captain Burstal, in his evidence before the Rivers Pollution Commission, when he was asked, "Was the Thames ever a very bright stream?" and his answer was this, "If you mean pellucid, I should think not, "but there is no doubt about this, that it was far "cleaner before steamers were invented than it has "been since; it is the steamers that stir the shore "up. If you go down the river and watch the action "of a wave made by a paddle wheel steamer, it is "something frightful; it will tear away masses as "large as this table from the saltings, and the rebound "mashes the muddy portions up, at least, it mixes up "the muddy portions with the water, and makes the "water turbid." That answer was given in the year 1866, since then the number of steamers has more than doubled, and the tonnage has more than trebled, and screw steamers are almost universal now.

13,891. (*Chairman.*) Do let me understand this; does Dr. Frankland or anybody else say that all the mud in the river comes from the sewers?—The case as it is put upon the other side is——

13,892. But does he say so?—Yes.

13,893. Does Dr. Frankland really say so?—Not Dr. Frankland, but Mr. Leach.

13,894. Then we know of our own knowledge that it is not true?—It has been stated on the other side that the deposits which have taken place at Erith are, in consequence of the mud, discharged from the outfall.

13,895. That is a different thing; it is one thing to say that all the mud in the river is produced by the sewers, but it is quite another thing to say that the mud at any particular spot has been very much augmented by the sewers?—Extraordinary as that assertion is, it was made by Mr. Leach upon the Mud Inquiry, and can be found for the Commission to refer to.

13,896. There can be no doubt that if it was made, it was wrong; but at all events it has not been made here.

(*Witness.*) But the importance of it is, that we are made in great measure responsible for the muddy and filthy state of the river, whereas if you analyse the mud, you will find the mud washed from the banks contains nearly as much polluting matter as the mud from the sewage.

13,897. (*Mr. Abernethy.*) That is to say, if you take the mud from the saltings, you will find them of very much the same character as you would find the mud opposite Crossness?—Yes, just so.

13,898. (*Chairman.*) If you were to take a spade full of the mud from a bank which has not been disturbed, which is as nature put it, if I may use the expression, would you find noxious matter in it?—Yes, it would be nearly identical in its composition with the mud found in the bottom of the river; that has been carefully analysed by the chemists. Now, I was observing that screw steamers stir up the mud more than the paddles, because the screw is nearer to the keel, and the motion goes deeper; and it is not the swell caused by the paddles only, but it is the great wave which is raised by the bows of the vessel, it is the increasing size and speed of the vessels now in use which has that effect upon the banks.

13,899. (*Sir John Coode.*) Is that disputed by anybody?—I think you will find that Captain Burstal spoke of the paddle steamers having had an effect upon the banks; that was put to him. There is another circumstance which also causes the effect produced by steamers now to be very much greater than it was formerly, and that is the increased height to which the tide rises; it therefore affects the banks

further up and overflows the saltings higher up; it soddens them and disposes them to be washed away.

13,900. (*Chairman.*) Does the tide rise higher up below London Bridge than it used formerly to do?—Considerably; it rises two feet higher since the removal of old London Bridge and the dredging of the river.

13,901. I should have thought the removal of London Bridge would have diminished the height of the tide below, whereas you say it has not?—No, on the contrary; a certain amount of tidal force is delivered at the mouth of the river, and that is destroyed in two ways, first, by the friction it meets arising from shoals or bridges, and the rest is exhausted by heaping up the water against gravity, so that the water rises very much higher at the top of an estuary than at the mouth. In the bay of Fundy the difference is as much as 120 feet. If you take away the shoals, and so reduce the friction, the force has then to be exhausted by heaping up the water at the upper end.

13,902. I can understand that the removal of London Bridge would cause the tide to rise a good deal higher at Teddington or at Richmond; but I should have thought that it would have tended to reduce the tide at the lower part of the river?—That is so, as far as it goes, but it is the removal of the shoals lower down the river which affects the lower part of the river. The removal of London Bridge principally affected the part above London Bridge. The question and answer have now been found in which Captain Burstal suggested that the paddle steamers produced a greater action upon the banks than the screw steamers, but I do not think it is worth while to pursue that. Now, not only have you the banks below being disturbed, but you have the banks above bridge which are being seriously diminished by the steam launches. In 1880 I spent a week in examining the banks of the river from Kingston to Oxford, and I found that throughout the whole length of the river the banks were being rapidly washed away. The Conservators have not the funds at their disposal to enable them to take protective measures to prevent the banks being washed away.

13,903. (*Prof. Williamson.*) What led you to the conclusion that they were breaking away?—I saw them cracked, and breaking down with the grass upon the top of them.

13,904. But you said they had been washed away?—If you have upon a river of that character a perfectly perpendicular bank with a sharp edge and pieces gone here and there, an engineer knows in a moment whether the bank of a river is breaking down, or whether it is in its natural state. I think that if the Commission were to refer to the reports made monthly by Colonel Bolton, they would find there a statement made as to the large quantity of detritus which is brought down.

13,905. (*Sir John Coode.*) Now you are speaking of the quantity brought down from above?—Yes, I am speaking of the quantity brought over Teddington Weir. In January he reported,—"The river was "again in a state of flood through the month, and "was much polluted by the effluent waters bringing "down from the land quantities of marl and clay, "as well as decayed vegetation and other impurities, "which stained the water and rendered it exceedingly "turbid." And in the 6th Report of the Rivers Pollution Commission, in investigating the metropolitan water supply, they give at page 269, as a specimen of the influence which the quantity of rain has upon the amount of deposit it contains, one page from the book kept by the West Middlesex Water Company.

13,906. (*Chairman.*) I should think the Commission are satisfied that the greater portion of the mud in the river does not come from the mud in the sewers but comes from the abrasion of the banks and from other sources?—I am happy to hear your Lordship say so, because the very reverse was contended in the other inquiry.

(*Mr. Abernethy.*) It was contended that there were certain banks which were composed of sewage mud.

(*Chairman.*) But one remembers the time when there were no sewers ran into the river at all, and there was a quantity of mud then, and one remembers a time when there were no steamers upon the river, and the mud lay upon the banks, and that after the introduction of steamers the banks were, in places, washed clean, but the mud is still there in certain parts.

(*Witness.*) What I am coming to is this, that if you were to shut out the sewage to-morrow, you would not make any tangible difference in the quantity of mud deposited upon those mud banks; and I am going to show the reason why mud banks were formed in those particular places, that it is not in consequence of their proximity to the sewage outfalls, but in consequence of other conditions which the engineers will entirely appreciate, and I am coming to them immediately.

13,907. (*Chairman.*) That is coming to the point?—This (*producing Plan No.* 19; *see Appendix AE.*) is a plan of one of the large saltings in the river. I have had this made to show the manner in which the banks break down; these saltings break down in all directions.

13,908. (*Sir John Coode.*) Where is Broadness, to which this refers?—It is near Gravesend. I would merely mention that the total length of bank upon the two sides of the river, at least upon the southern side from Kingston to All Hallows, and upon the north side from Teddington to Yantlett, is 133 miles, of which 43 miles, when I had the surveys made in 1879, were unprotected, and little has been done in the way of protection since. So that the extent of this washing away may be understood, more especially when I mention the rivulets which intersect them in all directions, and which therefore expose a very much larger surface than the mere shore line of the river.

13,909. That mileage you have just given us is measuring round the irregularities, is it?—No, only measuring round the coast-line. Then I would call attention briefly to Diagram 34 (*see Appendix BM.*), which is really plotted from observations which were taken jointly by Mr. Keats and Dr. Tidy at the close of the subsequent inquiry. Observations were made at Teddington for a month of the quantity of water flowing over the weir, and of the quantity of suspended matter contained in the water; and it was shown by the diagram that, whereas upon the 7th February, when there was no rain, the amount of suspended matter per gallon was only ·18, only five or six tons came over altogether. On the 21st, at a time of rain, the quantity of water increased by six times, and the quantity of suspended matter per gallon rose to 24 grains, so that the quantity of suspended matter which came over upon that day was 4,666 tons, as compared with six tons upon the previous day I have given.

13,910. Was that over Teddington Weir in one day?—Yes, over Teddington Weir in one day; and those are the joint results of the observations of the chemists on both sides, Mr. Keates and Dr. Tidy,—to settle in fact a disputed point. The observations were made conjointly.

13,911. And they agreed upon that view?—They agreed upon that view. The table is contained in the Mud Report, which I believe is before the Commission. Now my next proposition is one which I am sure will be assented to, that in a river so laden with mud, if you have slack water, mud must be deposited. I have here the sections which were just referred to, taken by Telford above London Bridge in 1823, and by Captain Shields below London Bridge in 1796, to compare with those that were taken by myself in 1843 (*shewing the sections*), and upon those I have coloured the deepening of the water blue, and the shoaling of the water red; and it is very striking how all the sections above London Bridge are blue, the river having scoured itself; but all the sections below London Bridge are red, showing the deposit which had taken place before 1843 in the 20 years.

*Mr. H. Law.*

30 May 1883.

13,912. (*Chairman.*) Will you explain that a little further?—Upon each of these sections there are two lines representing the bed of the river; the upper line is the river as found by Telford in 1823, and the lower line is the river as found by myself in 1843, deepened, therefore, to the extent of the blue colour.

13,913. (*Sir John Coode.*) What is the vertical scale of that section?—The vertical scale is 20 feet to the inch.

13,914. Do those two sheets refer to the same section of the river at different times, or are they continuous all the way down?—The sections commence at Vauxhall Bridge—on one sheet they extend to London Bridge—upon the next sheet they extend from London Bridge to Blackwall Point; and they show that owing to the removal of London Bridge the river began to deepen itself from natural causes; the diagram at the junction of the two sheets shows from Fishmonger's Hall to Hibernia Wharf; and here you have it remarkably clearly shown that the natural action of the river is, owing to the acceleration of the current by the removal of London Bridge, to scour away the material above and to deposit it in the Pool. In some places you will see enormous deposits. I have for convenience mounted them upon one sheet but they are all to be found in the first report of the Metropolis Improvements Commission, of which a copy will be supplied to the Commission.

13,915. (*Chairman.*) Are the reds deposits?—Yes, the reds are deposits, the blue being deepenings. The value of this diagram is to show what was taking place long before either the Thames Embankment was constructed or the interception of the sewers. I beg to hand in the Report from which they are taken.

13,916. (*Sir John Coode.*) The last date is 1843, and the first date is what?—The first date above London Bridge, is 1823 and below London Bridge is 1796.
